Stephen L. Wood'

## PREFACE

The first insect I examined critically and collected for permanent preservation was Trypodendron retusum LeConte. At the age of 14 years I was introduced to it by T. O. Thatcher on 21 June 1939 at Lehman Creek Canyon, White Pine County, Nevada, near the base of Wheeler Peak. The attraction was immediate and permanent. An important factor in reinforcing that initial attraction was W. J. Chamberlin's (1939) The Bark and Timber Beetles of North America, which kept the interest alive and served initially as a guide to its expansion.

The human population explosion of this century applied increasing worldwide pressure on forests and agricultural resources to increase the efficiency with which their products are formed. Since bark and ambrosia beetles constitute an important destructive element that interferes with this production and with the esthetic values derived from our forests, increased knowledge of these insects should be of value to our society in dealing with them. Because of the enormity of the task, I selected one small facet, fundamental in nature, for my contribution.

The first and most fundamental step in the solution of a problem in biology is the accurate identification of the organism under investigation. Without it, all else is meaningless, because effective communication is not possible.

Among my first experiences in scolytid taxonomy was the discovery that numerous errors in identification had been made. They were made partly because of a faulty species concept possessed by early taxonomists and partly because of a consuming desire on the part of a few authors to indelibly engrave their names in the annals of science by naming species they presumed were new to science. More recently, we have learned that the behavior of a population in nature determines whether or not it is a species, not the taxonomist. Many of the early contributions must now be rejected as a result. Even so, those early contributions established the foundation on which we now build.

There has been a tremendous need for a comprehensive review of the Scolytidae of North and Central America to aid in the identification of species and to serve as a guide and reference work in the training and

[^0]in the professional work of entomologists, foresters, and others directly or indirectly concerned with these insects. This volume treats a sufficiently high proportion of the fauna and is based on sufficient research involving primary types that it should serve as an important standard of reference for several decades to come.

With the exception of a few cited instances, all the work is original with me. However, in the early stages of preparation of the manuscript, well-intended colleagues knowingly published as new to science several species which I had in manuscript form in order to "make them available" to my study. As a means of self-preservation and to avoid an endless comedy of locating types, rewriting manuscript, etc., all species new to science and almost all new synonymy were published as discovered. Those descriptions were originally written for the present work and were modified only slightly to get them into print in the minimum possible time. To this extent this work partly duplicates published literature.

A working knowledge of the world fauna was indispensible to the present study. Thus far, 45 species introduced into North and Central America from foreign lands were found. Most of them had been named as native species and their true origins had not been suspected. As knowledge of the world fauna is increased, this number will expand. It will be most surprising if 10 to 20 additional introduced species are not now established and await detection.

The preparation of this work has been an educational experience far exceeding original expectations. It was conceived in 1952, although writing did not commence until 1967. It was scheduled for completion in 5 years; it took 12.

This work is dedicated to those who unselfish contributions to this aspect of my life made this study possible, most particularly to T. O. Thatcher, W. H. Anderson, J. M. Swaine, and W. J. Chamberlin; to my wife and children, who endured decades of hardship and sacrifice for it; and to those young enthusiasts who will find it useful, correct its weaknesses, and continue the work.

The National Science Foundation supported the project directly or indirectly through most of the period from 1959 to 1977. Appreciation is expressed to those officials and colleagues who made these grants possible.

Publication of this volume was sponsored by substantial grants from the Boise Cascade Corporation, the Weyerhaeuser Company Foundation, and the National Science Foundation. Their concern and foresight in the support of basic research in forest science is recognized and greatly appreciated-and in this instance especially needed. They are outstanding examples of the support and interaction that has and should exist between private enterprise and the scientific community.

Following the completion of this volume, Schedl (1979) published posthumously a catalog of the type material in his collection. Included were (1) several neotypes, which have no standing in nomenclature because they were not published in a revisory work, and (2) numerous lectotypes. Although many of the lectotype designations are valid, a high percentage of the species involved had previously selected lectotypes designated for them; complications pertaining to ownership of the material also cloud part of that action. Because the article did not become available until this volume was beyond recall, and because the work needed to mravel this unfortunate act was enormous, no attempt to deal with this problem was attempted here.

## INTRODUCTION

The dramatic increase in the human population during the present century has focused ever-increasing attention on forests and their products. This once unlimited natural resource no longer satisfies the demands placed upon it. These circumstances have led to an increased interest in forest protection and an awareness of the destructive capacity of forest insects. We have learned a great deal about the biology and ecology of many destructive forms and now know how to reduce or eliminate much of the loss. Although much has been accomplished, much more remains to be learned before a new ecological balance in a managed forest is achieved.

In the primeval forest an ever-shifting ecological balance existed between the natural reproduction and growth of trees and the depredations of insects, fire, floods, disease, and climatic factors. When great losses resulted from any one or a combination of these destructive agents, natural ecological succession gradually restored the balance. It wasn't particularly important that several hundred years might be required to restore the original forest.

A managed forest must satisfy a multiplicity of needs ranging from the most ethereal esthetic end of the spectrum to the economic realities of tree farming at the other end. Losses from insects, fire, and disease are regarded as avoidable and action may be taken to reduce or eliminate them.

Although insects superficially appear to be the least dramatic of the destructive agents in a forest, they actually kill more trees each year than the combined total of all other natural factors (R. F. Anderson 1960:203). Among the insects, one group consisting of the two families Scolytidae and Platypodidae, commonly known as bark and ambrosia beetles, stand alone in their destructive capacity. It has been estimated that, in the United States, 90 percent of all tree mortality is caused by insects and more than 60 percent of the total is caused by representatives of
the Scolytidae (Anderson 1960:203). The Platypodidae, almost entirely tropical in distribution, equal or replace the Scolytidae in this role in tropical countries. For a variety of reasons the Platypodidae will not be considered further in this volume.

More than 6000 species of bark beetles have been named from throughout the world wherever woody plants grow. About 477 species occur in the United States, with approximately 179 of these, plus a few endemic species, extending their ranges into Canada and Alaska (Bright 1976). About 605 species are found in Mexico and about 632 in Central America; allowing for overlap in distributions, there are about 1,430 species in North and Central America combined. Most species restrict their breeding activity to one or a limited number of host plant species. In addition, most species have specialized ecologically to infest only a restricted part of their host plant. For example, some species confine their attacks to the cones or fruits of their host, others infest only tiny twigs, others small branches, limbs, boles, or roots. Some breed only in shaded-out branches of standing, living trees, others in felled or broken material, etc. A few are very aggressive and attack healthy, living tissue, and others prefer dying or dead plants.

Because of the large number of species and the extreme diversity in their habits, bark and ambrosia beetle attacks on economically important plants can be evaluated and meaningful corrective action taken only if species involved are correctly identified. In addition, research notes based upon incorrectly identified specimens may not only be meaningless, but misleading. This volume was written to simplify the process of identification of Scolytidae for those who work with problems involving these insects. Coleopterists and zoogeographers will also find information compiled here useful in their work.

Three noteworthy attempts have been made to classify North and Central American

Scolytidae (Blandford 1895-1905, Swaine 1918, Chamberlin 1939). Almost as noteworthy are series of revisional and other taxonomic articles relating to classification by Hopkins, Blackman, Wood, and Bright. This volume attempts to summarize and update their contributions as well as to add new information not previously reported.

## BIOLOGICAL ACTIVITIES

## Ecological Nicie

Most bark and ambrosia beetle species live only in recently cut, injured, or unthrifty tissues of woody plants that are in the process of dying. In most genera, they complete one generation only in this material then abandon it to search for other material in suitable condition. Host tissues must contain sufficient moisture for the completion of development. Such material usually bears wilted or vellowish green leaves. Older host material usually is unattractive to the beetles; however, a few species apparently prefer host material that is completely dead. Several other species normally attack healthy, living tissue of vigorous plants and cause its death. A few species of ambrosia beetles (e.g., Corthylus columbianus Hopkins) are capable of attacking a living tree, completing a svstem of galleries, and emerging a generation later without killing the host, although a permanent scar remains in the wood.

Bark and ambrosia beetles usually are the primary attackers of recently injured or felled woody plants. Most species complete their development in about 20 to 90 days then move to fresher material. Other woodand bark-feeding insects usually arrive later or develop more slowly, thus reducing or eliminating competition. Those scolytid species with longer life cyeles and those arriving late in the ecological deterioration of their host usually encounter much greater competition for survival from other insect groups.

## Host Specificity

Most Scolytidae are restricted in the number and variety of host species in which they can successfully reproduce. In gencral, phloeophagous (phloem infesting) species tend to be more restricted or specific in their
selection than are xylomycetophagous (woodboring ambrosia beetle) species. The apparent reason for this difference is that the former feed directly on host tissues, and the latter feed on fungal spores; any host on which the symbiotic fungus can survive will be satisfactory for beetle development.

Only two known species Coccotrypes, tribe Dryocoetini), one in Malaya and one in New Guinea, confine their attacks to Pteridophyta. Representatives of 14 of the 25 tribes recognized here in the world fauna normally breed in Gymnospermae, but of the 10 most primitive tribes worldwide only the Hylastini, Tomicini, and Scolytini are included within these 14 . It is of interest that all species of the Hylastini are restricted to the family Pinaceae of the Gymnospermae. Representatives of all tribes, with the exception of Hylastini, breed largely or exclusively in the Dicotyledoneae, althongh the American Polygraphini occur exclusively in conifers. Fewer than a dozen known species confine their activities to Monocotyledoneae, but only one of these represents a primitive group (Cnesinus vestitus Eggers, tribe Bothrosterini). In addition to these, several species of polyphagous Xyleborus may also breed in various palm logs, but host preference is not involved in the selection.

Within tribal or generic groups host specificity may be extreme, with most species confining their breeding activity to one or to a very restricted number of host species. For example, American Scierus, Hylurgops, Hylastes, Carphoborus, Polygraphus, Cryphalus, Crypturgus, Dolurgus, Pityogenes, Orthotomicus, Pityokteines, Ips, and Pityoborus are restricted to the Abietineae of Pinaceae, Phlocosinus to the Cupressineae or Taxodioideae of Pinaceae (many Oriental species occur in other plant families), Phrixosoma to the Guttiferae, Dendrocramulus to the Cucurbitaceae, Pseudopityophthorus to the plant genus Quercus, etc. The Bothrosternini, Cryphalini, and Xyleborini are unusually polyphagous.

## Host Selection and Dispersal

Scolytid beetles are dependent upon their power of flight to move from their brood tree to a new host. The original pioneer beetles
are guided in their flight (primary attraction) by volatile oleoresins, terpene hydrocarbons, alcohols, or other substances given off by the recently injured or dying host tissue (Rudinsky 1966). When such odors are in the air, flight is oriented and usually proceeds upwind to the source; when attractive odors are not detected, the dispersal tends to be random.
The objective of this flight is the location of new host material, but the use of that material varies with the reproductive readiness of the insect. When the gonads are mature, as is usually the case, a new tree in which brood can be produced is sought. In many species, however, the beetles seek the green bark of a healthy host, where they bore into the outer phloem and feed or hibernate for a period of time before emerging to seek a host in which to reproduce. In some species the construction of feeding tumnels is not a regular habit but may function as an emergency means of waiting for the availability of suitable host material. At times these emergency tumels are formed in hosts not normal for the speeies and have resulted in numerous erroneous host records.

The original pioneer flight may be taken by either the male (e.g., Ips) or the female (e.g., Dendroctonus) beetle. but, regardless of which sex makes this flight, the habit is consistent for the species. Once a pioneer has found a suitable host, it bores in then begins to release a chemical sex attractant or pheromone that attracts both males and females of its own species to that host. Thus, subsequent flights are oriented by both tree volatiles and pheromones until sufficient beetles are present to overcome any resistance to the attack that might be given by the host.

## Climate

The factors which constitute climate, that is temperature, precipitation, humidity, soil moisture, sunshine, air currents, and air pressure, are of extreme importance in determining the distribution and abundance of bark and ambrosia beetles and of the predators, parasites, and other organisms with which they are associated. Except for a few hours once each generation, during which time the dispersal flight takes place, these inseets live
entirely within the host plant, where the sul)strate and micro-environment are remarkably constant. This constancy in the immediate environment has had an obvious effect on in-tra-populational variability and apparently has reduced the effect of climate; but certain long-range effects are clearly evident. For example:

1. In Canada and Alaska fewer than 10 percent of all scolytid species are xylomycetophagous, and more than 90 percent are phloeophagous; in Costa Rica and northern South America approximately 60 percent are xylomycetophagous, and 40 percent have other habits, only part of which are phloeophagous.

2 . Of the genera treated in the present study 50 percent (including far more than half the species) are largely or entirely tropical in distribution, 30 percent are largely or entirely temperate in distribution, and 20 percent occur in both areas (but a disproportionate majority of the species in these genera are tropical). Comparatively few species are found in Alaska and Canada and. among those that do occur there, the distributions of a high percentage of them are restricted to southwestern British Columbia or to the southern tip of Ontario.
3. Scolytid species are comparatively uncommon in deserts. A surprisingly high percentage of the genera present in desert regions are restricted to desert or semi-desert areas (Chactophlocus, Cactopinus, Stenocleptus, etc.).
4. Temperate groups of scolytids may extend their distributions into tropical areas along mountain ranges, providing the altitude is high enough to assure cool temperatures, and a dry season is sufficiently pronounced to produce conditions suitable for the growth of their host plants.
5. Unusually high or low temperatures cause fluctuations in bark beetle populations over extensive areas. High and low letlaal temperatures vary from species to species. from one developmental stage to another. and with the length of exposure (Rudinsky 1962). This principle has been used in controlling certain species by exposing infested material to solar radiation during the hot summer season. It is also noted that, in a fallen log, one species may infest the uppermost
(hottest and driest) surface, another may infest the sides (moderately cool), and others may infest the lower (coolest) area. In addition, it is observed (Dixon and Osgood 1961:3. Wood 1963:17-18) that, in a given widely distributed species, more generations are completed at the southern than at the northern limits of the range, presumably the result of a longer season of favorable temperatures.
6. Prolonged drought may reduce the resistance of trees to a point where they cannot resist bark beetle attack (Rudinsky 1962:342). Many species of twig borers cannot be reared successfully outside a growth chamber unless melted wax or liquid plastic is painted over cut ends to conserve moisture. lt is also a common practice of bark beetle collectors to cut limbs of trees and place them in a cool, shaded place, where moisture loss is minimized, so that they might remain attractive to scolytids.
7. In their dispersal flight bark and ambrosia beetles normally move only short distances (a few meters) from one host to another. Occasionally, however, these weak fliers are caught by the wind and carried distances up to 15 km (Rudinsky 1962). Their occurrence on certain oceanic islands suggests flights of considerably greater length.
8. Flood waters undoubtedly have had an effect on bark beetle populations, either by covering infested hosts and drowning the local population, or by carrying infested material downstream to initiate an infestation in a new area. Living larvae immersed in water cooled to near the freezing point have been kept alive by me for 200 days. Infested logs presumably could be carried completely immersed for hundreds of kilometers during spring floods and still produce living beetles.

## Hibernation anio Estivation

Unfavorably high or low temperatures, such as those encountered during the tropical dry season or the northern winters, cause a cessation of beetle activity. The life cycle usually is synchromized with the seasons, and the most resistant stage predominates when the period of physiological stress begins. Estivation, the period of inactivity during hot or dry weather, occurs principally in tropical
regions and apparently may be as short as two weeks or as long as five months, depending on the climate. In all probability, this inactivity is not controlled hormonally (except Xyleborus dispar (Fabricius)), but may be interrupted at any time by the return of favorable temperature and moisture.

High temperature.- Bark temperatures of $42-50 \mathrm{C}(107-122 \mathrm{~F})$ usually cause disorganized behavior of bark beetles and, in time, thermal paralysis, and death. Higher temperatures, $50-55^{\circ} \mathrm{C}(122-131 \mathrm{~F})$, are lethal in a shorter period of time.

Graham (1920, 1924) found in Minnesota that the thickness, color, structure, and surface features of bark and the light intensity, solar attitude, and angle of incidence influenced the subcortical temperature of logs. He found that midday subcortical temperatures reached maximum levels of 45-60 C, with the highest levels in dense, dark, thinbarked, rough logs. The highest levels of 60 C ( 140 F ) were reached in Pinus strobus on a day when the air temperature was 40 C (104 F).

Patterson (1930), using Pinus contorta logs in Oregon, recorded midday subcortical temperatures of $43-51 \mathrm{C}(110-123 \mathrm{~F})$ while air temperatures were $24-26 \mathrm{C}$ ( $75-78 \mathrm{~F}$ ); subcortical temperatures in adjacent standing trees were 22-24 C (72-75 F).

Miller and Keen (1960) summarized 45 years of studies on the effect of high temperatures on Dendroctonus brecicomis LeConte. Decreased activity was noted at $35 \mathrm{C}(95 \mathrm{~F})$ and thermal paralysis at $38 \mathrm{C}(100 \mathrm{~F})$. Currents of warm air with low humidity could be fatal to larvae at $38-41$ ( $100-105 \mathrm{~F}$ ) within 30 minutes. At "normal" humidity paralysis commenced at 42-43 C (108-110 F) and death at 43-46 C (110-115 F). No larvae survived even bricf exposures at $48 \mathrm{C}(118 \mathrm{~F})$. In field tests, sustained temperatures of 38 C ( 100 F ) resulted in 34.2 percent mortality, and at $49 \mathrm{C}(120 \mathrm{~F}) 100$ percent mortality.

Low temperature. - The mortality of bark beetles due to low temperature apparently is an important factor in determining local abundance and the expansion and contraction of distributions.

Beal (1933) reported that the egg stage of Dendroctonus brevicomis LeConte was the most resistant of all immature stages to low
temperature. Air temperatures of $-21 \mathrm{C}(-5$ F) did not affect the hatching of eggs; however, temperatures as low as $-12 \mathrm{C}(10 \mathrm{~F})$ resulted in 43 percent mortality of larvae in the moist cambium (moisture level 200 percent of dry weight) while larvae in the outer bark (moisture level 30 percent of dry weight) suffered ahmost no mortality. When exposed to $-21 \mathrm{C}(-5 \mathrm{~F})$, mortality of larvae was 100 percent, pupae 90 percent, and adults 100 percent in the moist phloem. Pupae and adults in the dry, outer bark suffered almost no mortality at this temperature.

Miller and Keen (1960:71-73) reported cold periods in the winters of 1924 (-29 to -32 C or -20 to -25 F ) and 1932-1933 (-29 to -39 C or -20 to -38 F ) in which Dendroctonus brevicomis , larval mortality was estimated at $25-80$ percent and $50-90$ percent, respectively. Unprotected summer brood larvae exposed in the laboratory at $-18 \mathrm{C}(0 \mathrm{~F})$ suffered 20-50 percent mortality, at -21 C $(-5$ F) 75 to 100 percent mortality, and at $-21.7 \mathrm{C}(-7.5 \mathrm{~F})$ almost always 100 percent mortality. At $10 \mathrm{C}(50 \mathrm{~F}$ ) larvae become sluggish and dormant; at -9.5 to -12.2 C ( $15-10 \mathrm{~F}$ ) larvae freeze but recover when returned to warm temperatures. A "brief" exposure of eggs at $-21 \mathrm{C}(-5 \mathrm{~F})$ resulted in 90 percent mortality; none hatched after exposure at $-23 \mathrm{C}(-10 \mathrm{~F})$. Results with the exposure of pupae were about the same as for larvae. Adult mortality commenced at -10 C ( 14 F ) and was complete at $-12.2 \mathrm{C}(10 \mathrm{~F})$.

Massey and Wygant (1954:23-24) studied the effect of low temperatures on cold-hardy Dendroctonus rufipennis (Kirby) and report 100 percent mortality at $-26 \mathrm{C}(-15 \mathrm{~F})$ for adults and $-34 \mathrm{C}(-30 \mathrm{~F})$ for larvae. Low temperatures in Colorado in 1951 extending in some areas down to $-49 \mathrm{C}(-56 \mathrm{~F})$ killed approximately 75 percent of the overwintering larvae above the snow line; adults hibernating below the snow line at the bases of their hosts were not affected by these temperatures.

Hopkins (1909b:24) attributed the complete extermination of Dendroctonus frontalis Zimmermann in Virginia and West Virginia to the unusually cold winter of 1902-1903.

Activity ravge.- From the above data it would appear that bark beetles are active at temperatures of about $10-38 \mathrm{C}(50-100 \mathrm{~F})$.

Daterman, Rudinsky, and Nagel (1965) report that the minimum threshold air temperature necessary to initiate flight ranges from 12-13 C (54-55 F) in Pseudohylesinus nehulosus (LeConte) to $20-22 \mathrm{C}(68-72 \mathrm{~F})$ in Scolytus unispinosus LeConte. It is noted, however, that once flight is initiated it may continue even though temperatures may decrease to 5 C ( 41 F ) in Pseudohylesinus spp.

The spring flight usually commences when daytime temperatures reach this threshold. As the season advances and temperatures increase, the period of flight is restricted to the early morning and evening periods to avoid desiccation.

Hibernation.- Whether or not the life cycle is synchronized with the seasons, most scolytids do not hibernate in the true meaning of the term. Instead, when subcortical temperatures fall below the threshold activity ceases; when temperatures rise above that threshold activity is resumed. In Xylehorns dispar (Fabricius) true hibernation occurs (French and Roeper 1972); however, the mechanism governing it has not been investigated.

The winter may be passed in any stage of development, but the overwintering stage is constant and characteristic in each species. The larval stage is the most commonly represented. Most species appear to make no special preparations for winter; others bore into the sapwood (e.g., Scolytus rugulosus Müller) or into the outer bark (some Dendroctonus): others fly to living trees where feeding tunnels are excavated in green tissue (e.g., some Phlocotribus), or they overwinter in the duff on the forest floor (e.g., Ips, Trypodendron).

Estivation.- This phenomenon has not been reported in the literature. In Costa Rica during the latter part of the dry season I found Metacorthylus velutinus (Wood) in an inactive state in radial tumnels $1-2 \mathrm{~cm}$ deep in a $\log$ too dry for reproduction. Apparently, they were waiting for spring rains before resuming activity. Tropical Dendrocranulus apparently pass the wet season outside their normal hosts, then appear in large numbers as the dry season begins. Hibernating specimens were not found. Many tropical scolytids apparently ignore the seasonal changes observed by other insects and continue their reproductive activity throughout the year.

## Ecological Spechimization

Each group of organisms entering a new adaptive zone, as chid the Scolytidae when they began to utilize unthrifty and dying tissues of woody plants, soon discovers that its food resource is limited and its greatest competitors for food and space are other members of its own kind. The resulting competition results in an adaptive radiation or ecological specialization along mmerons avemues that enables the group more completely and more effectively to utilize the available food source.

For example, it probably would be physiologically impossible for one species of scolytid to develop that could utilize both bark and wood of all woody plants in all parts of the world. Such an occurrence would subject that species to enormous population fluctuations and other matural disasters. It is of greater advantage to the group to develop a variety of species each specialized to meet the requirements of life in a particular climate on specialized tissie of a restricted host. This is essentially what has happened in the evolution of the Scolytidae.

Scolytids utilize at least some representatives of gymmosperms and virtually all dictyledonous families containing woody plants. Few species inhabit pterydophytes or monocots. While many woody plant species are not infested by any scolytid species, others (most Pinaceae, etc.) are the host of mmerous species. When two or more species share the satme host species, competition between them for space and food results either in extinction of one of them or in ecological specialization. Such specialization has resulted in the development of forms that live only in seeds or fruits (eertain Araptus, Coccotrypes. Conophthorus, Hypothenemus, Pagiocerus, spermophthorus, etc.), others only in muthrifty twigs aud branches of living trees (eertain Carphoborus, Chaptophlocus, Hypocryphalus, Liparthrum, Pityohorus, ete.), others in cut or broken twigs and branches (eertain Cryptocaremus, Cnesinus, Mypothenemus, Pityophthorus, Tricolus, etc.), others in suppressed seedlings in dense growth (certain Carphoborus, Pityophthorns, Xylechinus, etc.), others in the tops and limbs of overmature trees (certain Ips, Phlocotribus,

Pityophthorus, Scolytus, etc.), others in slash (certain Ips. Pityogenes, Pityophthorus, Scolytus, etc.), others in boles of standing trees (certain Dendroctonus, Ips, Phloeotribus, Scolytus), others in butts and stumps (certain Dendroctonus, Dryocoetes, Gnathotrichus, Ip.s, Xyleborus, etc.), and others in roots (certain Corthylus, Dryocoetes, Hylastes, Hylurgops, ete.). Some species utilize leaves (certain Cactopiuus, Hypothenemus, Pseudothysanoes, Scolytodes, etc.). and a few live in herbaceous plants (all Dendrocranulus, Hylastinus, certain Hypothenemus, etc.). Pagiocerus frontalis (Fabricius) has been reported as a minor pest in stored corn in South America, hut not in the northern parts of its range. Several species, particularly in the genus Hypothenemus, apparently are capable of living in almost any available source of plant material; for example, Hypothencmus cruditus Westwood was named from a series found boring in the cover of a book. It also may live in seeds, weeds, twigs, bark of the bole of large trees, and shelf fungi. Of greatest economic concern, however, are those species that infest healthy, living tissue, such as Conophthorus spp., Corthylus columbianus Hopkins, several Dendroctonus spp., Hypoth enemus hampei (Ferrari), Xylosandrus compactus (Eichhoff), and many others.

## Food and Feeding Habits

The Scolytidae are among the few insect groups in which the adults burrow into the host plant for the purpose of depositing their eggs directly in the food substrate to be consumed by the larvae. The concealed tumnels (Fig. 1) offer a greater degree of protection than oceurs in many groups; furthermore, the adults usually remain in their galleries to prevent the entry of predators and parasites into the gallery system, thus increasing the protection given to the larvae. Several forms of feeding are associated with this habit.

Herbrbiagy, feeding upon nonwoody plants, is rare in the Scolytidae. Hylastinus olvscurus (Marsham) breeds in the roots of various clovers and may become a serious pest. Chramesus pumilus (Chapuis) breeds in the larger stems of wild beans. Hyothenemus pubescens Hopkins breeds in the fruiting stalks of grass; H. eruditus Westwood, H.

arectae (Hornung), H. crudiae (Panzer), $I$. columbi Hopkins, and occasionally other species may breed in a wide variety of herbaceous vegetation, although they are not restricted to these plants. All Dendrocramulus species and allied Old World genera breed exclusively in the stems of cucurbitaceous plants.
Spermophagy includes feeding on seeds and at least parts of the protective fruit that covers them. In North America this habit is best known in the Conophthorns species that infest cones of Pinus, particularly those with large seeds. Spermophagy is much more common and widespread among tropical genera such as those listed in the preceeding section (Ecological Specialization).

Myelophagy, feeding on the pith of small stems, evidently is considerably more common in the American tropics than in other parts of the world. Several species of Pityophthorus have this habit in the United States and Canada. Almost all species of the Bothrosternini, all Cryptocarenus and Micracisella, several species of Hypothenemus, and a few species of Araptus, Chramesus, Scolytodes, Tricolus, etc., also have this habit. A few of these species are extremely aggressive and destructive.

Phloeophagy, feeding on phloem tissues of the inner bark, is the habit usually associated with this family and is the basis for their common name; however, fewer than half the species in the family are phloeophagous. In temperate areas of the world the most common genera burrow in the cambium region of their hosts and thereby produce the characteristic engravings that show on the surface of peeled bark or wood. Most of the Hylesininac, Scolytini, Ctenophorini, Dryocoetini, and I pini fall into this category.

Xylopiagy includes living in and feeding directly on the xylem or wood tissues. Although almost all ambrosia beetles may be partially xylophagous, they are excluded from this category since their principal food is not xylem. Apparently all xylophagous species are associated with fungi that alter the character of the wood consumed, but the mycelium does not form a conspicnous element of the diet. Xylophagous forms inchude Chramesus xylophagus Wood, two species of Chaetophloeus, all Dendrosimus, Lymantor,

Hylocurus, Micracis, and Thysanoes, Scolytodes multistriatus Wood, and many other isolated examples in other genera. I am unaware of any nutritional studies involving a xylophagous species; the food source and the modified color and texture of the wood near a tunnel suggest that symbiotic organisms are involved in some way.

Xylomycetophagy includes the cultivation and utilization of a symbiotic fungus as a food source. The term "ambrosia beetle" has been applied to the Scolytidae and Platypodidae having this habit regardless of their phylogenetic origin or relationships. The habit apparently has arisen independently in the Platypodinae of the Platypodidae and in the Scolytidae in the Bothrosternini (Bothrosternus), Hylesinini (Hyleops of Australia), Scolytini (Camptocerus), Scolytoplatypodini (Scolytoplatypus of Asia and Africa), Xyloterini, Xyleborini, and Corthylini. More than 99 percent of all species of Platypodidae and more than half of all tropical Scolytidae have this habit.

## Galleries

The gallery systems of the Scolytidae are unique and represent the product of a long and complicated evolution. These beetles probably arose prior to the Cretaceous geological period from a saprophytic group of beetles found under bark. Early representatives probably formed crude cavities in the phloem after entering the bark through injuries or the excavations of other insects. The earliest galleries probably were of the cave type similar to those presently seen in Mecopelmus (Platypodidae), many Scolytodes, Cryphalus, Procryphalus, Trypophloeus, and phloeophagous Coccotrypes, in which the eggs are deposited individually or in small clusters and mixed indiscriminately in the frass. Later the eggs were placed in specially prepared niches and packed in a mixture of boring dust held together by an adhesive secretion, as now seen in Liparthrum. Further specialization of the system included the extension of various irregular pockets for the protection of the eggs; these eventually became egg galleries and may occur either with or without egg niches. The addition of the polygynous and xylophagous habits modified the basic gallery only slightly.

The gallery system of a typical phloeophagous or myelophagous species consists of the following parts:

1. Entrance tunnel: The entrance hole (Fig. 2: parts 5, 11, eh) is usually located at a leaf scar, axil, crevice, or other irregularity in the bark; however, many Micracis and Corthylus, and genera allied to these two, commonly select smooth areas. This short, simple, cylindrical tumnel is usually directed obliquely upward in its passage through the bark to facilitate frass removal and, apparently, to protect the entrance from precipitation. In xylophagous forms (Fig. 2: parts 12-14, 16-18) it is a direct radial tumnel perpendicular to the outer surface. The diameter of the entrance tumnel is very slightly larger than the beetle making it, such that its body might effectively prevent the entry of predators, parasites, or other unwanted intruders when a defensive position is taken in the entrance tumnel. A major task of one of the parent beetles is blocking the entry.
2. Nuptial chamber: In many groups, when the entrance tunnel reaches the cambium a flattened (tabular) cavity is usually excavated (Fig. 2:5, 11, NC). This oval or irregular chamber usually has a diameter about three to five times greater than the length of the beetle excavating it. The entrance tunnel usually enters the nuptial chamber at its lowest margin to facilitate frass removal. In the most primitive gallery systems adult participation in excavating the tunnel ends at this point; as indicated above, eggs are scattered indiscriminately or in clusters and larvae enlarge the excavation. In most groups, however, additions are made. The nuptial chamber is best developed in groups in which the male forms the initial parts of the system, particularly when polygyny occurs. It is partly or entirely eliminated in other groups, particularly when a male does not enter the gallery.
3. Egg galleries: When a female enters a tunnel she forms one or more egg galleries (Fig. 2:1-16) that extend along the cambium following a course away from the nuptial chamber. They usually are straight, but curve characteristically in some species. Very commonly it is possible to identify the genus or even the species from the gallery system without seeing the beetles that made it. In
their primitive form egg galleries are no more than indefinite pockets along the margin of the nuptial chamber. In their more advanced form they are more slender and longer, and in their most advanced form they are cylindrical, very slightly larger than the width of the beetle forming them, and very long. In most genera the female cuts egg niches along the margins of the tumnels: in others these are absent. The egg niches usually are as wide as the female head and about as deep as wide; their size, shape, position, and spacing usually are characteristic. Long egg galleries in thick bark usually have ventilation tunnels placed at irregular intervals on the outer side. These extend to near the surface of the bark but rarely open to the surface. Their function is not definitely known but they might serve as turning niches, as sources of oxygen, for ventilation and temperature control, or as easily opened avenues of escape in an emergency.
4. Larval mines: After hatching the larvae may (a) feed exclusively on mycelial or other materials supplied to them, (b) enlarge the parental chamber, usually feeding communally (in congress), or (c) form individual larval mines. The latter habit is by far the most common in temperate regions. Larval mines may be little longer than the larval body (Pityoborns, etc.), or exceedingly elongate (some Scolytus, etc.). Though the egg gallery, nuptial chamber, and entrance tunnel are usually kept entirely free of boring dust, the larval mines are closely packed with frass. In many species the larval mine engraves both wood and bark throughout its. length; in others part or all of the mine may be entirely in the wood or entirely in the bark. Near the end of the larval mine an expanded area is usually cleared to form a pupation chamber where transformation occurs. It may be formed in the cambium region. deep in the xylem, or in the outer bark. Following transformation many species emerge immediately through individual exit holes: others require a maturation feeding period before they emerge. The brood of phloeophagous and myelophagons species rarely emerges through the parental entrance hole. although it does in Pityoborus, in many Cryphalini, and in most ambrosia beetles.

Fig. 2. The common kinds of gallery systems lorned by Scolytidae: 1, biramous longitudinal; 2, monoramons longitudinal: 3, stellate, radiate, or multiramons; 4, cave-tumel (two postoriposition feeding tumels are shown); 5, stellate system of Ips concimus showing entrance hole (eh), nuptial chamber ( NC ), egg gallery (et), egg niche (ep), larval mine (1g); 6 , modified stellate; 7 , transverse stellate; 8 , transverse biramous; 9, longitudinal stellate; 10 , transverse biramons with larval mines added; I1, moditied stellate with metial chambers entirely in the bark; 12, ambrosial stellate without cradles (Xylehorus); 13, ambrosial cave-tumel (wood grain rums left to right; in 12 wood grain rums top to bottom); 14, ambrosial stellate with larval cradles (Monarthrum); 15, pith tumel (Micracisella); 16, ambrosial stellate, modified, with eradles (poor example of Gnathotrichus): 17, 18, ambrosial branching tumels (Xylehorus obesus). (After Swaine 1918:13.)

In xylophagous and in most spermophagous forms the same basic parts of the gallery system are found except that they are distrubuted in a three dimensional system rather than two.

In ambrosial forms the larval mines are usually reduced to larval cradles just large enough to accommodate the new adult or they are eliminated. In most groups having larval cradles the eggs are deposited in niches and the larva enlarges this niche into the cradle as it grows (Monarthrum, Trypodendron, etc.). In some Corthylus the parents form the completed cradles and deposit the eggs only when the ambrosial fungus is well established. In other groups that lack egg niches and larval cradles, the larvae may develop in the adult galleries (many Xyleborus) or the larvae may form a common, tabular chamber parallel to the grain of the wood. Numerous variations of these basic patterns occur.

## Gallery Patterns

Scolytid parental galleries might be classified as follows (Fig. 2):
I. Cave-tunnel: A simple cavity formed (1) in the cambium region, (2) in the wood, or (3) in the pith of small stems. When this type of cavity is formed by ambrosia beetles (Xylosandrus), most or all of the cavity usually is formed by the larvae.
2. Uniramous gallery: A simple, (a) longitudinal or (b) transverse egg gallery either in the phloem or xylem tissues. Primitively, a conspicuous nuptial chamber occurs at or near the entrance; this chamber may be reduced to a turning niche or, in galleries made by previously mated females, it may be eliminated.
3. Biramous gallery: A system in which two egg galleries arise from the same nuptial chamber. In its more advanced form the nuptial chamber may be eliminated and the pattern is a simple fork. The galleries may be (1) longitudinal, (2) transverse, or (3) diagonal. Among phloeophagous groups it is the most widely distributed pattern. It also occurs in some xylophagous groups.
4. Stellate, radiate, or multiramous gallery: This type of system is most common in polygynous species. Three or more
(19 were found in one species of tropical Pityophthorus) egg galleries extend from the nuptial chamber. The egg galleries may be (1) straight and radiate in all directions away from the nuptial chamber, (2) curved so as to (a) parallel the grain of the wood, (b) cut transversely across the grain, or (3) form a pattern independent of the grain.
5. Branching galleries: This type of system is rare and apparently occurs only in species communally sharing the same entrance hole, as in Dendroctonns brecicomis LeConte, Cladoctonus boliviae Wood, apparently Microborus spp., and a few other species. In this system, beetles arriving late at the host use a previously made entrance tumnel and follow the gallery of another pair for a distance before starting their own branch tunnel. Phloeophagous species that form tumnels of this type do not remove the frass from the gallery, but pack it tightly a short distance behind the working area. This is also one of the most common systems formed by ambrosia beetles, although the entrance may or may not be communal.
6. Ambrosia beetle galleries: Ambrosia beetles construct gallery systems of the five basic types listed above except that (a) they are adapted to a three dimensional system rather than two, and (b) the larvae may extend and modify the original parental tumnel. as indicated in the preceding section, either the larvae or adults may form series of larval cradles in either one or two ranks both above and below the egg gallery (ambrosial Corthylini, Scolytoplalypodini, and Xyloterini). In many of the Xyleborini the larvae form tabular extensions of the parental tunnel along the grain of the wood that sometimes are enormous when one considers the size of the beetle.

## Social Organization

As with other woodboring Coleoptera in which the adults form tunnels and euter the host to reproduce, the Scolytidae have developed a distinctive subsocial behavior. Most species infest hosts that are unthrifty or in a somewhat living though injured state. When the beetles bore into these living tissues the host reacts by exuding quantities of resin to plug the wound and expel or drown the

Fig. 3. Pitch tube of Dendroctonus brevicomis showing an unsuccessful, expelled beetle on a pitch tube. (Atter Keen 1955:2.)
intruder (Fig. 3). If only one or a few beetles are present a vigorous host usually is successful in resisting the attack. Most scolytids overcome this resistance through mass attacks that overwhelm the resistance of the host. The communication necessary for coordinated attacks is accomplished through secondary attraction with pheromones released by the beetles.

The original pioneer beetles that first enter a new host release one or a combination of chemical substances (pheromones) begiming about the time their tumnels reach the cambium region. These volatile substances are in the fecal pellets that are mixed in the frass and expelled from the tumel by the beetles. The odors carried by the air currents have a strong attraction to both males and females. Upon arrival at the host moder attack the members opposite in sex from the pioneers, seek out an entrance tumnel and, through the process of auditory, tactile, or possibly chemical signals, or a combination of these, the potential mate is identified and admitted to
the tumnel. Following mate identification, pheromone production ceases. A masking or repellant pheromone may also be released after the mate is admitted (Rudinsky 1968). An extensive annotated bibliography on secondary attraction in Scolytidae was published by Borden and Stokkink (1971) and Borden, VanDerSar, and Stokkink (1975).

As indicated above, one of the principal functions of pheromones is the attraction of potential mates. The secretive habits of these insects, coupled with their ability to communicate through olfactory and auditory signals, has led to the development of unique reproductive behavior. When the potential mate arrives at the entrance hole, in certain species, it stridulates actively. This stridulation in male Dendroctonus pseudotsugae Hopkins causes the female inhabitant of the new gallery to stop the production of the aggregating pheromone and to admit the male ( Ru dinsky 1968). In Platypodidae this courtship apparently includes tactile as well as auditory elements, and in certain genera (Diapus) the female mandibles are equipped with special processes used for identification by the male, which are shed after this event. The elaborate sexually dimorphic sculpture and ornamentation of the head and declivity in one or both sexes of numerous species of Scolytidae suggest that tactile stimuli are used extensively in the Scolytidae for mate identification at the entrance of the gallery. Chemical stimuli also function in this courtship activity, in addition to basic secondary attraction (Rudinsky and Michael 1972).

There are four distinct types or levels of social organization associated with reproductive behavior. These are (1) monogamy, (2) normal (heterosanguineous) polygyny, (3) extreme (consanguineous) polygyny involving arrhenotokic parthenogenesis, and (4) gynogenetic parthenogenesis.

Monogamy is the most common and widely distributed habit. It occurs in all Platypodidae (except Protoplatypus), in all Hylesininae (except Polygraphini and some oriental Phlocosinus), in Scolytini (except some neotropical Scolytus), in Ctenophorini (except a few Scolytodes), in all Scolytoplatypodini, Cactopinini, Crypturgini, and Xyloterini, in phlocophagus Micracini, in part of the Cryphalini (Cryphalus, Hypocryphalus,

Stegomerus), in part of the Dryocoetini (Dendrocranulus), and in part of the Corthylini (Pityoborus, Conophthorus, Corthylus, many Araptus, and a few Pityophthorus). In monogamous species either sex may initiate the boring of a new gallery, but the habit is constant within a species. For example, in Dendroctonus and most Scolytus species the female performs this function, but in Phloeosinus and Corthylus it is the responsibility of the male. In most monogamous species, after pairing has occurred, the female is responsible for boring egg galleries, the formation of egg niches, and laying of eggs and caring for them and the larvae (if the larvae remain in the parental tunnel). The male keeps the nuptial chamber and entrance tunnel clean and expels the frass from the entrance hole. He also blocks the entrance with his body to prevent the entry of predators and other intruders. Kalshoven (1959:170) observed rapid pumping movements of the body (stridulation of a disturbed individual?) and quick, short movements backwards and forwards in the tunnel near the entrance and suggested that these activities might be associated with ventilation of the gallery system. Although similar action has been observed in other Scolytidae, its function has not been investigated.

In monogamous species both sexes usually participate in the construction and care of the galleries. However, in many forms one or both sexes may abandon the tumnel as soon as egg deposition or hatching is complete, and in a few Scolytus the male may mate on the bark surface and never enter the gallery system. One or both sexes may then participate in the formation of a second, third, or even fourth set of galleries (Simpson 1929).

The division of labor in tending the gallery system apparently has led to the evolution of much of the observed sexual dimorphism in the groups. Most of these features occur either on the head or elytral declivity and, as suggested above, many of them may be associated with mate identification. However, others clearly are associated with frass removal, preparation of the niches for the eggs, or cultivation and care of the ambrosial fungi. The most radical modifications include the head and antennae (Camptocerus, Hylocurus, Corthylus), pronotum (Amphicranus,

Pityoborus), elytral declivity (Ips, Monarthrum, Amphicranus), abdomen (Scolytus), and legs (Xyleborini).

Polygyny occurs in many tribal groups and undoubtedly has originated independently several times. Two distinctive types of polygyny are recognized: (1) Heterosanguincous and (2) consanguineous polygyny. In heterosanguineous polygyny the male flies to the new host and (almost always) excavates the entrance tumel and nuptial chamber. He then admits about two to five females to his chamber (up to 19 females were admitted in one neotropical Pityophthorus). The females then push the frass resulting from their activity into the nuptial chamber. The male has the responsibility of ejecting their frass and of protecting the entrance hole. The function of each sex is about the same as in monogamous species. The advantage appears to be the greater speed and efficiency with which the host can be occupied. In addition, a portion of the more vulnerable attacking males can be lost to weather and predation without affecting the population. This polygynous habit occurs in Phloeosinini (some oriental Phloeosinus), Polygraphini, Scolytini (certain neotropical Scolytus), Ctenophorini (polygynous Scolytodes), Micracini, most Dryocoetini, Ipini, and Corthylini (except several monogamous forms and two species noted below). ln most xylophagous Micracini, in Pseudopityophthorus, and in some neotropical Scolytus the male is always associated with two females; a different number may characterize other groups.

In consanguineous polygyny the males are incapable of flight and, consequently, they almost never leave the brood chambers. The deformed, dwarfed, haploid males attain sexual maturity and mate very early and usually die before they are fully colored. The sex ratio of the brood in these species ranges from about 3-50 females per male. Both mated and unmated females may attack the new host. Entwistle (1964) reported that in Xylosandrus compactus (Eichhoff) unmated females, and those that have exhausted their supply of sperm, produce only haploid males by facultative arrhenotokic parthenogenesis. The haploid males mate with either their mother or their sisters in order to produce diploid females (see also Norris and Chu
1970). Thus, an isolated female whether or not she has mated prior to isolation, is capable of colonizing a new area. Since both males and females have been observed to wander outside their galleries, it is apparent that some outbreeding might occur if they enter other galleries. Due to the recency of the discovery of the genetic mechanism, it is only speculation that male haploidy occurs in other tribes with consanguineous polygyny. This habit occurs in many Cryphalini (Hypothenemus, Cryptocarenus), in a few Dryocoetini (Coccotrypes, Ozopemon), in all Xyleborini, and in two species of Corthylini (Araptus laevigatus (Eggers) and A. costaricensis (Schedl)).

Reproduction by gynogenetic parthenogenesis was discovered in Ips tridens engelmanni Swaine by Hopping (1961, 1962) and was confirmed by Lanier and Oliver (1966). In this example it appeared as though the penetration of a sperm in the egg membrane is required to trigger a parthenogenetic response. Theylytoky, in which female offspring are produced with no participation of the male, has not been reported but almost certainly occurs in a few species such as Bothrosternus foveatus (Blackman), where males are mknown.

## Seasonal History and Development

Mate identification.- In all monogamous and heterosanguineous polygamous species, the first step toward the production of a new generation, after the host has been selected and the new gallery is started, is the identification and admission into the gallery of one or more potential mates. The admitting sex has initiated the gallery and tightly blocks the entrance with its body in order to prevent the entry of a predator, parasite, or competitor. Mate identification to gain entry into the obstructed entrance may involve the exchange of sound stimuli (Rudinsky and Michael 1972), behavioral stimuli (Petty 1977), and, apparently, chemical stimuli, or a combination of two or more of these factors. Female Diapus (Platypodidae) have special mandibular processes that are shed after fulfilling a tactile function. Following mate identification, either a position for copulation is taken or else the chosen mate is admitted into the gallery.

Mating. - As indicated in the preceding section, a diverse social order has had its effect on mating behavior. In most species with heterosanguineous polygyny and in many phloeophagous monogamous forms (Dendroctonus, etc.) copulation takes place only after both sexes have entered the new gallery system. In these species it most commonly occurs while one member is in the nuptial chamber or turning niche and the other is in the entrance tumnel or at the entrance of an egg gallery. In this protected site it may occur repeatedly throughout the period of oviposition. In Platypodidae, Scolytus, Trypophoeus, Procryphalus, and probably in other monogamous groups, copulation occurs when the female is partly or wholly in the gallery, with her abdomen protruding above the surface, and the male is on the surface of the bark (Petty 1977). In the Platypodidae the male initiates excavation of the tumnel, but, following a courtship or identification ritual, he backs out of the burrow to admit her. Copulation then occurs and he follows her into the gallery (Browne 1961:38). In Scolytus quadrispinosus Say the female starts the burrow and, after mating occurs, the male may then enter the tumnel or go in search of another female (Goeden and Norris 1965:772). Males of Scolytus as well as Trypophlocus and Procryphalus (Petty 1977) commonly struggle for dominance by butting or pushing with the head until the loser is upset and falls from the bark. In Cryphalus mating may take place on the bark surface of either the brood or parental host (pers. obs.). Species with the consanguineous habit of polygyny have been observed on numerous occasions copulating in the brood chambers (pers. obs.).

Eggs.- Scolytid eggs are smooth, oval, white, translucent, delicate objects varying in size from one group to another (Fig. 4B). In certain small Hylesininae (Carphoborus) the egg may be almost one-third as large as the adult body; in larger species (Dendroctonus) they are proportionately much smaller. They vary in number in one gallery system from as few as 3 (Corthylus) to about 200 (Dendroctonus). The number of eggs apparently is smaller in ambrosia beetles and in those species inhabiting highly diverse tropical rain forests and greater in phloeophagous forms

Fig. 4. The four life stages of Dendroctonus brecicomis: A, adult; B, eggs; C, larva: D, pupa. (After Keen 1955:3.)
that breed in temperate forests where large stands of one or few host species predominate. In some groups the eggs are depos-
ited in clusters of about 4 to 20 (Trypophocus, Scolytodes) or separately but packed in frass in the parental chambers (Chaetophloeus); in Dendroctonus valens LeConte (etc.) they are deposited in rows in long or short grooves; in most scolytid species they are deposited individually in specially prepared niches and packed in boring dust that is held together by a secretion presumably of oral origin (probably from the maxillary glands). Hatehing may require from as little as 3 days (tropical Scolytodes) to as much as 30 days or longer (subarctic Dendroctonus). Variations in temperature may drastically alter the time required for incubation. Under ideal conditions the eggs of most species hatch in about 7 to 10 days.

Larvae. - The larvae are white, legless grubs with lightly sclerotized heads (Fig. 4C). They do not change appreciably in form as they grow. Although studies by Thomas (1957) and Lekander (1968a) have greatly increased our knowledge, the larvae are poorly known and deserve considerably more study. The number of larval instars varies from two to five. Lekander (1968b) gives the following based mostly on European species: (a) those having five instars include Chaetoptelius, Hylurgopinus rufipes (Eichhoff), and Dendroctonus micans (Kugelann) (for a variety of reasons I suggest a reexamination of these species before five instars are accepted for any scolytid species), (b) four instars were reported for Dendroctonus pseudotsugae Hopkins and D. simplex LeConte, Hylastes, Hylurgops, and Tomicus; (c) three instars occur in all lpini (except Pityogenes hopkinsi Swaine, which he suggests is an error). Dryocoetes autographus (Ratzeburg), Pityophthorus, Xyleborus, Hylesinus, and Polygraphus; and two instars in Conophthorus, Crypturgus, Cryphalus, and Emoporus.

The length of the larval period varies from as little as 12 days (estimated for some tropical Scolytodes) to more than two years (aretic Dendroctonus). Under ideal conditions it ranges from about 30 to 90 days in most species. The larvae may feed in congress while extending the parental chamber (Cnesinus, Scolytodes, Dendroctonus valens), or they may form independent mines (Ips, Pityophthorus). Their tumels may be long and tortuous (Phlocoborus, some Phlocotribus), or just
large enough to accommodate the adult body (Pityoborus, Monarthrum). Most Xyleborus and Corthylus larvae depend entirely on tunnels excavated by their parents.

Pupae.- Usually, the end of the larval mine is enlarged slightly and cleared of frass to form a pupal chamber. In other forms the larva may bore into the wood (Scolytus rugulosus) or into the outer bark (Dendroctonus approximatus Dietz) before forming the pupal cell. The pupal stage (Fig. 4D) may range in length from about 3 to 30 days, but tends to average about 6 to 9 days under ideal conditions. It rarely is selected as an overwintering stage except in areas where the winters are very mild.

Adver:- Upon transformation to the adult stage (Fig. 4A) the beetles may emerge immediately, even before becoming fully colored (Scolytus), or they may require a period of maturation feeding before emerging (some Dendroctonus, Ips). Many species fly from the brood host to a living host, where they excavate maturation feeding tunnels in living tissue before reaching reproductive maturity (Scolytus multistriatus (Müller), etc.). Others use this as an optional habit only when suitable host material is not immediately available for rearing their brood. After completing one gallery system it is not uncommon for the parent beetles to reemerge and construct a second, third, or fourth system of tumnels to produce an equal number of broods. A previously mated female will sometimes produce a second brood without the association of a second male, thus giving a false impression that parthenogenesis has occurred. A few old adults may survive the winter and participate in the production of the spring brood. However, a majority of the adults die in their tumnels after producing one brood. Chapman (1956) demonstrated that the flight museles of parent adult Trypodendron lineatum (Olivier) deteriorate during oviposition and brood production, but regenerate later when flight is again required. Vité and Rudinsky (1957) present a technique for estimating the degree of maturity in each of the developmental stages of Dendroctonus pseudotsugae. The progressive appearance of various structures and pigmentation enabled them to estimate the approximate age of each developmental stage.

Reproductive cycles.-As indicated in the preceding sections, scolytids are able to complete their life cycles in as little as 20 days or they may require at least two years. Temperature and moisture factors in the subcortical microclimate have a tremendous influence on life cycles and can radically shorten or prolong them. Some species, such as Dendroctonus ponderosae Hopkins, have one annual life cycle closely correlated with the seasons. Others may have two or more generations per year equally correlated with seasonal change. Many species, however, have a succession of overlapping generations complicated by the production of several broods from a given set of parents each year, as in Polygraphus rufipennis (Kirby). Even those species usually follow definite annual patterns of emergence, flight, etc. Dendroctonus pseudotsugae in the southern Rocky Mountains apparently has a life cycle out of sequence with the seasons, but has predictable outbreaks (Furniss 1965). In tropical areas cyclical activity in most forms is correlated with the dry and wet seasons and may be just as conspicuous as in temperate regions.

## Pheromones

Bark beetle pheromones, airborne long distance chemical messengers that announce to others of their species the location of host material or the availability of mates, have received much attention in the past decade. Since their main function is the coordination of activity in local populations, it has been supposed that they might also be used to disorganize normal behavior patterns and thereby achieve control of economically important species.

Pheromones have been reported in the Hylesinini (Hylesinus), Tomicini (Dendroctonus, Pseudohylesinus, Tomicus), Phloeosinini (Phloeosinus), Polygraphini (Carphoborus, Polygraphus), Scolytini (Scolytus), Ipini (lps, Pityogenes, Pityoktcines, Orthotomicus), Xyloterini (Trypodendron), Cryphalini (Cryphalus), and Corthylini (Pityophthorus, Gnathotrichus) (Borden and Stokkink 1971). They apparently have not been reported from any species with the habit of consanguineous polygyny.

The pheromone of male lps paraconfusus Lanier consists of three terpene alcohols; I. (-)-2-methyl-6-methylene-7-octen-4-ol; II, (+)-cis-verbenol; and III, (+)-2-methyl-6-methylene-2, 7-octadien-4-ol (Silverstein, Rodin, and Wood 1966). Although none of these was an effective attractant alone, compound I in combination with either II or III was partially attractive. It is of interest that compound I was marginally attractive to Ips latidens LeConte, but I and II used together were highly attractive; the addition of compound III eliminated the response (D. L. Wood, Stark, Silverstein, Rodin 1967). Cameron and Borden (1967) report that female response to the male I. paraconfusus pheromone fluctuates with the season, being lowest in January ( 24.2 percent response) and highest in May and June ( 76.6 percent response). D. L. Wood and Bushing (1963) found that the I. paraconfusus pheromone appeared in the frass about 9-12 hours after males were introduced into preformed entrance tumnels. The substance is produced only after feeding commences, indicating that the precursor is ingested and metabolized or else that food activates specialized secretory cells; it is passed from the adult male in the fecal pellets (D. L. Wood, Browne, Silverstein, and Rodin 1966). Borden and Slater (1969) induced pheromone secretion by topical application of juvenile hormone, indicating that the pheromones are secreted. The sensilla trichodea on the antennal club are the olfactory recepters for these substances in Ips (Borden and Wood 1966).

As examples of how pheromones function. the following is included. The principal sex pheromone of female Dendroctonus breticomis, exo-7-ethyl-5-methyl-6, 8-dioxabicyclo [3.2.1] octane, designated as brevicomin, occurs in the hind gut (Silverstein, Brownlee, Bellas, Wood, and Browne 1968). Males of this species produce as their chief pheromone 1, 5-dimethyl-6, 8 -dioxabicyclo [3.2.1] octane, or frontalin (Kinzer, Fentiman, Page, Foltz, Vité, and Pitman 1969), this substance is the principal pheromone of female $D$. frontalis Zimmermann (Renwick and Vité 1969). In $D$. brevicomis, brevicomin attracts mostly males and frontalin attracts females (Pitman 1969). In addition to the above, the pheromone complex of both $D$. brevicomis and $D$.
frontalis includes trans-verbenol in the females and verbenone in the males. (Transverbenol is a prineipal mass aggregating pheromone in female 1 ). ponderosae.) In all three of these Dendroctonus species volatile components of host resin, in addition to one or more pheromones, were necessary to produce mass attack. In $I$. frontalis and $D$. ponderosae the terpene $\alpha$-pinene was the most effective; in $D$. brecicomis $\alpha$-pinene, $\beta$-pinene or myrcene used separately, or the latter two in combination were effective in combination with pheromones (Renwick and Vité 1970, Bedard̉, Silverstein, Wood 1970). In contrast to that seen in Ips, D. frontalis, and apparently in other Dendroctonus species, pheromone release may commence before breeding begins (Vité and Crozier 1968). In D. frontalis frontalin and trans-verbenol are released by the female immediately upon reaching the host tree. As boring commences the addition of $\alpha$-pinene enhances their attractiveness, resulting in a mass attack in which males predominate about 3:1. As males arrive they produce verbenone, which reduces the response by other males. When the concentration of verbenone reaches a sufficiently high level the response of both sexes is inhibited and the attack then focuses on neighboring trees. In $D$. brecicomis the pattern is similar except that trans-verbenol does not appear to have a significant function. A small amount of frontalin is also released by female $D$. brecicomis and is highly attractive when combined with host resin (Vité and Pitman 1969). In $D$. ponderosae $\alpha$-pinene attracts the pioneer beetles to the host. These femates then produce trans-verbenol 12-16 hours after feeding commences, which. in combination with a-pinene, attracts large numbers of males and other females (Pitman. Vité, Kinzer, Fentiman 1968). Although the males produce brevicomin in substantial quantities, the function of this substance is not known in this species. The attraction stops when trans-verbenol and $\alpha$-pinene production are discontinued (Vité and Crozier 1968). In D. pseudotsugae the pheromone frontalin, together with the monoterpene camphene, induces mass attack on Douglas fir (Pitman and Vité 1970). Two additional components of the D. pseudotsugae pheromone complex have been identified, namely
the ketone 3-methyl-2-cyclohexen-1-one and the alcohol 3-methyl-2-cyclohexen-1-ol, but their functions in communication have not been determined (Vité, Pitman, Fentiman, and Kinzer 1972).

Pheromones probably occur throughout the Scolytidae and play a vital role in the survival of species. They are an important isolating mechanism. The occurrence of various chemical substances and their biological function appears to follow definite patterns. A thorongh knowledge of the composition of pheromones and their distribution within the family should greatly enhance our understanding of phylogeny within the family.

## ECONOMIC LOSSES

## Ecological Role in a Primeval Forest

In a primitive forest one of the greatest obstacles to continued growth is the recycling or removal of dead and dying plants. A slowing or stagnation in the removal of this material throws the entire ecosystem out of balance to the great disadvantage of most organisms contained in it. The Scolytidae breed principally in unthrifty, broken, overmature, and dying woody plants. Usually they are the first biological agents to attack these tissues. Not only do they consume the tissues of their hosts, but they introduce or provide avenues for the entry of other disease-causing or saprophytic agents that accelerate the deterioration of dead or dying plant material. The removal of these suppressed, stagnated, injured, diseased, unthrifty, and fallen trees opens the way to more vigorous growth of the surviving plants in a healthier forest community.

## Host Susceptibility to Attack

Trees differ significantly in their susceptibility to bark beetle attack depending upon their site, vigor, age, and physiology. Over a period of time these seemingly minor differences in susceptibility may alter the character of a forest, at least locally, or eliminate certain tree species from marginal sites.

It is generally recognized that trees growing on poor sites are more vulnerable to attack that those growing on choice sites. A
conspicuous example is seen in certain arid areas of the western United States where trees growing on chronically dry sites rarely attain maturity before being killed by bark beetles. Wet sites, near the margin of moisture tolerance for the species, have a similar effect in other areas. Miller and Keen (1960:155) indicate in their summary of work with Dendroctonus brevicomis that slowgrowing trees are attacked more readily than vigorous trees whether they are on a poor or a good site. They also report that considerably more beetles are required to kill a vigorous tree than one growing at a slower rate. In ponderosa pine fast growth, thick bark, and large heavy crowns are associated with this resistance. When there is an increase in the number of susceptible trees in a given area the bark beetle population is high; when there are few susceptible trees it is low. However, when the beetle population is high the degree of selection is reduced and previously resistant trees are also killed. Under epidemic conditions they report (p. 159) a tendency for the fast-growing trees to be attacked, except that in any age class the first trees attacked were either suppressed, showed evidence of injury, or had deteriorating crowns. Once these "key trees" were occupied, the attack spread to neighboring trees regardless of size, vigor, or other factors.

In view of the above, Keen (1936, Miller and Keen 1960:177) developed a system of ponderosa pine classification based on age and vigor in an effort to predict which trees were most likely to be attacked (Fig. 5). That system was replaced (Keen and Salmon 1942) by a more accurate, simplified risk rating that measured current tree health. Removal of all high risk (Class 4) trees in California did not result in greater infestation of trees in the remaining three classes (Miller and Keen 1960:187). In Oregon, only 67 percent of the predicted total volume of loss of high risk trees on a 640 acre plot were actually killed by insects over a five-year period; the removal of such trees resulted in a 90 percent reduction in infestation ( p . 188). It must be recognized that sanitation salvage can be practiced only on well-managed forests with suitable access roads. There are also complicating factors that make it difficult to

Fig. 5. The classes of risk in ponderosa pine to western pine beetle attack. No. 1, Low risk: full, healthy foliage. vigorous crown, dark green needles long and coarse, virtually all twigs with normal foliage, no weakened areas in crown. No. 2, Moderate risk: fair to moderately healthy crowns, with some imperfect areas, needle length average or above, color fair to good, some twigs and branches lack foliage but without definite weak areas. No. 3. High risk: crown health fair to poor, ragged or thin in some areas, fohage thin in some areas, needles shorter than average, their color fair to poor, some to many twigs and branches lack foliage or are fading or dead, with small, localized areas of crown weakened. No. 4. Very high risk: crowns ragged or thin, often with active insect infestations in upper areas. foliage thin or bunchy, needles short, sparse, color poor, parts of crown weakened, twigs and branches dead in some areas, active top-killing often evident. (After Miller and Keen 1960:183.)
apply the above California example to other tree species in different geographical areas.

Bark beetles differ in their ability to tolerate tree resins (Smith 1963). Individual trees also differ in the monoterpene composition of their resins (Smith 1966). In addition, Smith (1964) demonstrated that ponderosa pine trees being attacked by Dendroctonus brevicomis differed significantly in monoterpene content from neighboring trees not attacked by this species. From these and other data it is evident that host resistance to insect attack can be improved through plant breeding. Significant developments in this field are expected in the near future.

## Competition for Food

Other kinds of insects, in addition to Scolytidae and Platyodidae, feed upon the tissues of woody plants. Because of their small size and limited ability to cope with the altered microenvironment, bark and ambrosia beetles usually do poorly in competition involving robbery of the food source. Most species avoid conflicts by being the first to infest the unthrifty or dying tissue and rear their broods before the eggs of competitors hatch. Those scolytids with long life cycles and those arriving late at the host commonly experience difficulty in completing their development
without being subjected to the starvation or physical disruption that results from competition.

Round-headed borers (Cerambycidae) and flat-headed borers (Buprestidae) are the families of greatest concern. When abundant, larvae of these families may remove up to 75 to 95 percent of the phloem of a given tree (Blackman 1931:52). These larvae usually are considerably larger and live much longer than do the scolytids. When they encounter scolytid tunnels they consume all phloem tissues without deviating from their course and thereby destroy the occupants. Those that do escape often are unable to complete their development due to the changed phloem ecology.

Another kind of competition results from overcrowding by members of the same species. In most phloeophagous scolytid species the larval mines are independent of one another and never cross except under unusual circumstances. Often, when crowding is extreme, tunnels of larvae near maturity merge or cross and one is usually killed by the other. When young larvae are involved it is not uncommon for some of them to die in their separate individual mines without apparent cause. The resulting mortality benefits the total population by permitting at least part of them to attain maturity.

Several scolytid species, including Carphobius arizonicus Blackman, many Micracisella species, and other twig beetles often breed most commonly in small branches girdled by Cerambycidae. In most of these instances the scolytids complete their life cycle and emerge before the cerambycid larvae become large enough to be a factor in scolytid survival.

## Relation to Fire, Slasif, and Natural Disasters

Fire.- When properly controlled, fire has long been used in maintaining certain types of forest growth and it has been used to control and destroy broods in bark beetle infested trees.

Fire of sufficient intensity will destroy broods under the thin bark of some trees without burning the bark of the infested tree. Uninfested trees may be sufficiently
dehydrated by the heat that their tissues are unsatisfactory for brood development. However, trees slightly injured by fire that ordinarily would recover from their injury often are highly attractive to bark beetle attack and may serve as the focal point of a developing epidemic. Broods in infested trees with thick bark are rarely injured by fire unless the bark is burned from the trees (Miller and Keen 1960:220).

Bark beetle species react differently to fire. Dendroctonus ponderosae and D. valens are reported to attack fire-injured trees almost immediately after the burn, but $D$. brevicomis is not attracted to the burn but concentrates on surrounding trees a year or two after the burn (Miller and Keen 1960:220, etc.). Certain buprestids and cerambycids that normally breed in drier tissues than do scolytids are much more abundant in fire-injured trees. In most instances, D. pseudotsugae is dependent for population buildup upon slash and trees that are windfallen, fire-injured, or damaged by other natural disasters. In Tillamook County, Oregon, a major fire in 1933 resulted in the loss of 200 million board feet of Douglas fir during the following threeyear period due to D. pseudotsugae (Chamberlin 1939:83, Bedard 1950).

Following epidemics in which Dendroctonus beetles kill substantial numbers of trees, these dead snags constitute a forest hazard in the event that a fire occurs in the area. The presence of such trees greatly enhances the speed and intensity of the fire, making them a factor to be considered in forest protection.

Slash.- Numerous species of insects, particularly bark and ambrosia beetles, breed in slash, cull trees, logs, and stumps. Most of those species breed only in slash and other dead material and are of no economic concern other than that they accelerate the deterioration of this dead plant material. In the larger material, however, they can create a definite problem in some areas. Dendroctonus rufipennis, D. pseudotsugae, D. murrayanae Hopkins, and, to a lesser extent, other species in this genus and most species of Ips normally breed in this material. Epidemics of these species, whether due to individual species or combinations of them, commonly are traced to an initial population
buildup in slash, stumps, and windfalls. The insects then turn to green timber when the supply of dying material is exhausted (Chamberlin 1939:84, Craighead 1927, Graham 1922, Hopping 1915, Patterson 1927).

In the tropical and subtropical areas of the world the most serious timber losses to insects result from the boring of ambrosia beetles (Xyleborus, Monarthrum, and Platypodidae) in logs either in the forest, in decking areas, or at the mill. Similar damage occurs in Oregon, Washington, and British Columbia by Trypodendron lineatum and Gnathotrichus spp. In the tropics swarms of ambrosia beetles often hover about while waiting for a tree being cut to fall and begin boring in before it is cut into logs. It is not uncommon for the sapwood to be so heavily infested that it is entirely discarded when the logs reach the mill. Populations of these ambrosia beetle species usually build up in small trees destroyed by logging road construction before felling begins, and in slash thereafter. Occasionally populations reach a level where green timber is killed, but such attacks are limited and of short duration; epidemics in green timber do not develop. Although statistics on losses in the American tropics do not exist, one major operator at Barinas, Venezuela, indicated that one-fourth to one-third of the total volume of logs reaching his mill was discarded due to ambrosia beetle damage by Xyleborus ferrugineus (Fabricius), X. affinis Eichhoff, X. volculus (Fabricius), and Platypus parallelus (Fabricius).

Natural disasters.- During severe thunderstorms, lightning may strike trees. These injured trees are favored breeding sites of several Dendroctonus and Ips species and may serve as a center from which epidemics develop. It is much more common for severe local winds to blow down large numbers of mature trees in which populations build up then move to green timber.

## Relationships with Fungi and Disease

Based upon numerous field observations and a few laboratory tests, it is apparent that most, if not all, Scolytidae are associated with fungi. The relationships evidently range from the most casual, or perhaps accidental, contact to intimate mutualistic bonds in which
neither the fungus nor the beetle could survive without the other.

Some phloeophagous bark beetles, particularly such genera as Carphoborus, Chaetophloeus, and others that live in rather dry tissue, show little or no evidence of association with fungi. In other phloeophagous species and virtually all xylophagous forms, such as Dendrosinus, Hylocurus, Micracis, Phloeoborus, and Thysanoes, the tissues in the immediate vicinity of the tunnels are either discolored or in a state of decay far in excess of that found a few millimeters from the tunnels. It is suspected that the nutritional value of xylem is so low that fungi are required to modify it or synthesize other products from it before it can be used as a food source. In addition to those scolytids that use the host tissues as the primary food source, a composite assemblage of unrelated groups of ambrosia beetles culture fungi on their tunnel walls and use the spores as their primary food.

Bramble and Holst (1940) report that the fungus infestation in trees attacked by Dendroctonus frontalis Zimmermann includes a complex of species. The primary invasion that interferes with transpiration and kills the tree is by Dacryomyces sp. and Zygosaccharomyces pini. Later, Ceratocystis pini takes the lead in infesting the deeper sapwood and staining it blue to black. Trichodema lignorum and Monilia spp. are present. but apparently are secondary invaders of host tissue. These blue stain fungi discolor infested wood, thereby reducing its value, but not its structural quality (Francke-Grosmann 1963). Ceratocystis ips, associated with Ips calligraphus (Germar), I. pini (Say), and I. avulsus (Eichhoff), has a similar effect on pine, as does Trichosporium symbioticum (brown stain), carried by Scolytus ventralis LeConte on Abies concolor.

Graham (1967) reviews the mutualistic relationships between fungi and scolytidae and lists the various genera involved.

The blue stain fungi are transported in special integumental sacs, termed mycetangia, by the female beetle. They are inoculated into living host tissue soon after the tunnels reach the cambium region. The mycelium grows very rapidly and interferes with the plant's transpiration. Although there may be some blockage of conducting vessels, other

Fig. 6. Oral mycetangia of a female Dryococtes confusus: b, brain; ts, fungus upores; ms, mycetangial setae: my, mycetangia. (After Farris 1969:528.)
factors are involved that result in the rapid death of the host. This reaction in Clmus to Ceratocystis ulmi (tramsmitted by Scolytus multistriatus (Marsham)) is known as Dutch Elm Disease, and the reaction of Theobroma cacao to C. fimbriata (transinitted by Xyleborus ferrugincus, etc.) is the wilt disease of cacao. These and other Ceratocystis species are associated with a wide variety of other bark and ambrosia beetles (Hylurgops, Hylurgopinus, Orthotomicus, Xyleborus, Trypodendron, (nathotrichus) and produce somewhat similar effects on other plant species.

The scolytids' transmission of spores of their symbiotic fungi to their host is not a simple mechanical process. In many instances the spores are incapable of germination until they have passed through a definite period of maturation, which may include proliferation within the body of the beetle. As might be expected in any mutualistic relationship that has reached this level of dependency, the beetles have developed inflections of the body wall into which special glands discharge their mutrient secretions, where the spores are protected and preserved (FranckeGrosmann 1963). These mycetangia apparently have taxonomic significance relative to their location on the body and other features. They have been classified as:

1. Oral mycetangia. - Saclike pockets at the base of the mandibles beneath the epipharynx that open into the pre-oral cavity. They have been reported in Dryocoetes confusus Swaine (Fig. 6), Xyleborus affinis, X. andamanensis Blandford, X. fornicatus Eichhoff, and X. velatus Sampson.
2. Pronotal mycetangia.- Saclike invaginations on the pronotum occur in Dactylopalpus and Scolytoplatypus and in mumerous Platypodidae.

## 3. Prothoracic-pleural mycetangia.-

 These are saclike invaginations in the propleural area of the female. In Trypodendron (Fig. 7) and Xyloterinus they occur near the posterior margin; in Bothrosternus and Phlocoborus they are near the anterior margin; in Dendroctonus brevicomis, D. frontalis, and allied species they open at the anterior margin in the cervical membrane.4. Prosternal-subcoxal mycetangia.The coxal cavities have enlarged areas (Fig. 8) where spores proliferate in Gnathotrichus retusus (LeConte), G. sulcatus (LeConte), Monarthrum mali (Fitch), and M. fasciatum (Say). From superficial examination it appears that all xylomycetophagous Corthylini have similar mycetangia.
5. Pro-mesonotal mycetangla.- A pair of invaginations in the intersegmental membrane may be (a) overlapped by and extended beneath the posterior area of the pronotum, as in Xylosandrus germanus (Blandford); (b) curved so as to lie beneath the anterior part of the mesonotum, as in Xyleborus dispar (Fig. 9); or (c) the mesonotum may be

Fig. 7.-Prothoracic pleural mycetangia of a female Trypodendron lineatum: Co, procoxa; Dr, mycetangium; Md, orifice of mycetangium. (After Francke-Grosmann 1956:117.)
involuted to form a spiral mycetangium, as in Eccoptopterus spinosus (Olivier).
6. Elytral mycetangia.- A cavity in the anterior margin of the elytra near the scutellum, which is supported by a cluster of setae surrounding the cavity, occurs in Xyleborinus saxeseni (Ratzeburg) (Fig. 10) and, apparently, in all other representatives of that genus.

## Introduced Species

The geographical distributions of animal species are not constant, but expand or contract in response to various natural fluctuations in the environment. In addition, interaction between species may offer mexpected opportunities for range expansion. For example, human commerce has had a conspicuous effect on the distribution of many Scolytidae (Marchant and Borden 1976). The extent to which commerce has affected the North and Central American fauna is summarized by Wood (1977).

Thirty-seven species were introduced to North and Central America and established as breeding populations from an Old World source (Table 3). Of these, 7 were of

Fig. 8. Prosternal-subcoxal mycetangia of female Monarthrum scutellare. (After Farris 1965:31.)

European origin, 13 were from Africa, and I8 were from southeast Asia (including Indonesia and neighboring islands). It is of interest that 31 of the 37 can reproduce by facultative arrhenotocic parthenogenesis, a means by which an unmated female can establish a breeding population. Only two of these 37 are known to have been introduced more than 100 years ago. Of the 6 bisexual species, 4 were introduced more than 100 years ago.

Of 25 North of Central American species that have extended their ranges within or beyond this area (including the adjacent islands), 17 of them have reached areas in the Old World (including Hawaii). Of these 17, 11 can reproduce by facultative arrhenotocic parthenogenesis. It is not known that any of these 25 reached a non-American area (or Hawaii) prior to 1900 . Only 3 of the 8 species that have extended their ranges in America, but have not reached an area outside the Western Hemisphere, have this reproductive habit.

Fig. 9. Promesonotal metangium of female Xiyleborus dispar: I, pronotum; II, scutellum; III, metanotum; e, elytra; is, mycetangimm; d, mycetangial gland: pel, spores in mycetangimm. After Francke-Gromann 1956:288.)

It is apparent from the above that many bark and ambrosia beetles have extended their ranges through commerce and that

Fig. 10. Elytral mycetangiun of female Nylchorinus saxesemi: I, pronotun; II, scutellum; III, metanotum; e, elytra: d, mycetangial gland; pd, spores in mycetangimm. After Francke-Grosmam 1956:290.)
those species having the facultative arrhenotocic parthenogenesis reproductive habit are most likely to successfully establish extraterritorial breeding populations.

Table 1. Breeding populations of Scolytidae introduced into North or Central America from a non-American orisin. The species are listed alphabetically.

| Species | Origin | Introduced to |

## Control

Losses Attributed to Scolytidae
In a natural forest the Scolytidae perform a vital role in the maintenance of vigorous growth and in the recycling of dead plant tissue. However, their activities come in direct conflict with man when he diverts forest products for use in his economic or cultural system.

The economic effect of Scolytidae ranges from beneficial values to enormous economic loss. Those species that confine their attacks to shaded-out branches on living trees, such as Carphoborus, Pityoborus, some Pityophthorus, etc., accelerate a natural pruning process that is usually beneficial to vigorous tree growth and reduces the fire hazard. Natural thinning of suppressed, wind-thrown, broken, and injured trees also tends to be beneficial in a similar manner except in those cases where such material can be removed and utilized; Pityophthorus, Xylechinus, Pseudohylesinus, Pityogenes, some Ips, and various ambrosia beetles are the principal genera involved in a coniferous forest. Such species
become an economic problem when commercial logs are attacked. The destruction of cones in Pinus by Conophthorus is of marginal importance unless rapid reproduction or other use of seed is important. The destruction or injury of living twigs in Pinus by certain Pityophthorus, etc., may have a comparatively unimportant stunting effect on growth, but, more importantly, they may weaken the trees sufficiently to make them vulnerable to aggressive tree-killing species and may transmit plant diseases. The major conflict between scolytid activity and human interests is directed in a natural coniferous forest at the removal of overmature trees or stagnated growth and involves mostly Dendroctonus and $I p s$ species. In deciduous and tropical forests very different conditions prevail. The transmission of disease (Dutch Elm Disease, etc.) or the activities of ambrosia beetles in logs may cause the principal economic effect.

The actual monetary loss caused by bark and ambrosia beetles is unknown. Tree mortality caused by bark beetles in North America probably exceeds that of all other agents combined, including fire (Massey 1974).

Values given in the literature vary from author to author and probably are not entirely reliable; however, there is some agreement on the most destructive forms. It is estimated that Dendroctonus brecicomis destroys an average of more than two billion board feet of standing timber each year; $D$. ponderosae, $D$. rufipennis, D. frontalis, and perhaps D. pseudotsugae each average about one-half billion board feet annually. Other Dendroctonus, Scolytus, and Ips species inflict lesser but significant losses in coniferous forests. No measure of losses to fruit trees by Scolytus rugulosus, to elm trees by S. multistriatus, to forage crops by Hylastinus obscurus, to ornamental and horticultural plants by Xylosandrus compactus, or to coffee by Hypothenemus hampei has been attempted, but the value is immense. Less spectacular losses caused by numerous other species in the temperate region could be cited.

Economic loss caused by scolytids in tropical areas is usually less spectacular and not as easily measured as in temperate areas. It includes the destruction of commercial logs within days after they are cut, by ambrosia beetles; the destruction of seeds and fruits by seed borers; the transmission of disease, such as the wilt disease of cacao, by ambrosia beetles; and the reduction of growth and productivity by twig borers, etc., at much more intensive rates and on a scale not seen in northern areas. Mass attacks on healthy trees are virtually unknown. The damage is much more subtle and difficult to assess.

## Natural Control

Bark and ambrosia beetle populations in nature fluctuate enormously from one season to another and from year to year. These fluctuations may be correlated with life cycle, with biological opportunity, or with other factors inherent in the population or in the environment. All organisms have the capacity to reproduce at a rate greater than is necessary to perpetuate the race. If any species were to reproduce at its maximum potential rate, it would completely destroy its food supply and severely disrupt the biotic community in which it lives after only a very few generations. Natural factors within the community counteract the biotic potential to
maintain populations at a more or less constant but fluctuating level.

Factors such as climate, weather, health and vigor of the host population, and natural disasters have a significant effect on insect populations and, at times, have a controlling effect on them. In addition, biotic factors have a more subtle, but often a more constant and significant effect in reducing or controlling populations. These factors include insect parasites and predators, predaceous mites, insectivorous vertebrate animals, nematode parasites, and disease. A prime objective in forest management should be the encouragement of these indigenous enemies in order to reduce the length and intensity of bark beetle epidemics or, possibly, to prevent them from developing. In some instances they have destroyed more than 90 percent of the bark beetle brood in a given generation.

Insect parasites.- Various species of Lonchaeidae (Diptera) are found in bark beetle tumnels and are regarded as parasites (technically they actually may be predators).

Among the Hymenoptera, the families Brachonidae (Atanycolimorpha, Atanycolus, Bracon, Callihornius, Cenocoelius, Chelonus, Coeloides, Colastes, Cosmophorus, Cryptoxilos, Dendrosoter, Doryctes, Ecphylus, Eubadizon, Glyptodoryctes, Helconidea, Heterospilus, Opius, Orgilus, Paraecphylus, Russellella, Spathius, Triaspis, Vipio), Bethylidae (Cephalonomia, Scleroderma), Chalcidadae (Trigonura, Perniphora), Diapriidae (Cinetus), Encyrtidae (Microterys), Eulophidae (Entedon, Pediobius, Tetrastichus), Eupelmidae (Eupelmus, Eusandulum, Metapelma), Eurytomidae (Eurytoma, Ipideurytoma), Gasteruptiidae (Autacus), Ichneumonidae (Aplomerus, Campoplex, Dolichomitus, Gambrus, Gelis, Helcostizus, Neoxorides, Odontocolon, Xorides), Mymaridae (Ooctonus, Polynema), Podagrionidae (Euchrysia), Proctotrupidae (Cryptoserphus), Pteromalidae (Acerocephala, Amblymerus, Caudonia, Cecidostiba, Cheiropachus, Coelopisthia, Dipachystegma, Elachertodomyia, Habrocytus, Halicoptera, Heydenia, Hypopteromalus, Psilocera, Psilonotus, Pteromalus, Rhaphitelus, Rhopalicus, Theocolaxia, Tomicohia), and Torymidae (Liodontomerus, Roptrocerus) were listed by Bushing (1965) as containing species parasitic on Scolytidae.

The Pteromalidae genus Karpinskiella is unique in that it parasitizes adult scolytids.

Coeloides dendroctoni Cushman (Brachonidae), an important parasite of Dendroctonus ponderosae in Montana and Washington is selected as an example of the parasitic Hymenoptera. The mated adult female wasp flies to a tree attacked the previous August where the host scolytid larvae are now about half grown (DeLeon 1935a). As she crawls over the surface she uses her antennae to detect the movement of a larvae. Once a larva is located she positions herself on the bark then inserts her ovipositor in the bark, pierces the larval cuticle, then deposits one egg on the surface of the larva. The egg hatches in 1 to 4 days by which time the host larva becomes inactive and appears paralyzed (apparently the result of something introduced by the female parent). The newly hatched parasite crawls over the surface of the paralyzed host until it finds a suitable place to feed. It then punctures the host cuticle and sucks up the fluid that exudes. Growth requires about 10 days. The pupal cocoon may be spun immediately after growth is completed or it may be delayed up to 60 days. The pupal stage may require about two weeks or it may serve as the overwintering stage. Two to two and one-half generations per year may occur, with three principal periods of emergence distributed from late May to late August (DeLeon 1935a).

Insect predators. - The coleopterous families Cleridae, Colydiidae, Cucujidae, Elateridae, Histeridae, Nitidulidae, Rhizophagidae, Staphylinidae, and Trogositidae are reported by Chamberlin (1939) as major predators of Scolytidae. The Othniidae and the genus Hypophloeus of Tenebrionidae may also function as important predators.

The dipterous genus Medetera (Dolichopodidae) is an unusually important predator during its larval stage. The adults of Medetera aldrichii Wheeler tend to congregate on the surface of trees recently attacked by Dendroctonus ponderosae (DeLeon 1935b). The females place single or small clusters of eggs under small scales of bark on the surface of the trees. In 10 to 14 days the eggs hatch and the young larvae move to the inner bark, where they feed on eggs, larvae, and pupae
of the host. Other small insects are also acceptable prey. The larval period apparently may vary from 1 to 11 months. Pupation occurs in a silken cocoon beneath the bark and requires about 14 to 17 days. Adults apparently emerge through beetle exit holes, cracks in the bark, etc. It was estimated by DeLeon (1935b) that 40 to 50 percent of the bark beetle brood was killed by this species in Montana and Washington.

Many other predaceous insects may prey upon adult bark beetles during the flight period and some may significantly reduce populations. For example, a heavy attack by Xyleborus spathipennis Eichhoff in Costa Rica was virtually eliminated by ants as the beetles attempted to begin new galleries (pers. obs. 1966).

Mite predators. - The extent to which mites prey upon scolytids is not fully known. Moser and Roton (1971) reported 96 species of mites associated with Dendroctonus frontalis, of which 3 (Iponemus, Tarsonemidae) are known predators and several others are suspected predators. Lindquist (1969) reviewed 18 species of Iponemus, 16 of which are considered egg parasites of Scolytidae. Kielczewski (1976) reported more than 170 species of mites associated with 57 species of bark beetles in Poland; the ecological role of most of them is not yet known. Many of the mites are phoretic and are carried from one host to another by the beetles.

Female Iponemus mites are phoretic on the emerging brood of the bark beetle tribe Ipini. In the new tumnel the previously mated mite leaves the beetle and crawls along the egg gallery until it locates a niche containing a newly deposited egg. The mite enters the niche and the beetle seals it in with the egg with a plug of tightly packed frass. It apparently is not possible for a mite to enter an egg niche after the frass plug is in position. After piercing the cuticle of the egg, the mite engorges on its contents, causing her idiosoma to swell into a sphere. Engorgement continues until the sphere is approximately equal in size to the host egg (about 0.5 mm ). About two days later egg laying commences and continues for several days. Her body then turns dark, becomes flaccid, and dies. Approximately 40 to 80 eggs may be produced by each mite; these usually form a cluster
about her body. The mite larvae emerging from the eggs apparently require no food and rarely move. The larvae, slightly larger than the unengorged parent, apparently derive energy from the fat content of their own bodies. They pass into an inactive, turgid "pupal" stage without molting, from which they emerge as adult mites. Males emerge first and mate with females as they emerge. The females are very active and disperse from the maternal sphere after mating. About two weeks are required for development.

Insectivorous vertebrates.- Of the forest birds, woodpeckers stand alone as the important predators of bark beetles. They are particularly conspicuous during epidemics, where they have been reported to destroy up to 75 percent of the beetle population (Massey and Wygant 1954:18). Their feeding activity accelerated drying of the bark and resulted in the mortality of far more bark beetles than were eaten. Miller and Keen (1960:92) report the reduction of a Dendroctonus brevicomis population in California on ponderosa pine of 73 percent and in Oregon of 72 percent on trees heavily worked by woodpeckers; however, only a small percent of the infested trees were heavily worked by woodpeckers.

Amphibians, reptiles, and mammals (particularly rodents) will feed voraciously on bark beetles and their larvae when the bark is peeled from a tree. Under normal circumstances, however, they feed on them only incidentally during the flight period except for those species (Ips, Trypodendron) that overwinter on the forest floor.

Nematode parasites.- Massey (1974) summarized the biology and taxonomy of nematode parasites associated with bark beetles. Of 33 species of beetles examined in quantity, 31 were infested by nematodes. He found that the rate of infestation varied within any population (0 to 90 percent) and fluctwated in a given area from one year to another ( 15 to 80 percent). The reasons for the fluctuations are not known. A majority of the nematodes are carried from one host to another beneath the wing covers, in the intersegmental folds of the abdomen, and on the tarsal and tibial joints of the legs. Most of
them are obligate parasites and usually do not kill the host.

The nematodes are either oviparous or ovoviviparous. Immature stages are deposited in the beetle egg galleries by infested beetles. Males develop to maturity in the tunnels and impregnate immature free-living females. Immediately after mating the impregnated females penetrate the cuticle and enter the body cavity of the host, which is a larva in about the second instar. Eggs or larvae are released into the body cavity, following which the young larvae penetrate the gut and are then eliminated with the fecal material. The nematode life cycle is usually synchronized with that of the host, so both attain maturity at about the same time.

Diseases. - Although many viruses or polyhedral diseases are known for insects, none have been studied in the Scolytidae. Numerous fungal organisms, some of which may be pathogenic, have been observed on scolytids, but their effect on a population is unknown.

## Applied Control

A forest is a living, dynamic community that may change dramatically in response to fluctuations and modifications of environmental factors. As indicated previously, in a natural forest bark and ambrosia beetles play an important role in maintaining the health and vigor of the trees by removing stagnated growth and by accelerating the recycling of dead material. Because their natural function in a managed forest usually conflicts with human interests, however, they are transformed from a beneficial to a destructive element. As such, they are regarded in North America as the most destructive natural biotic factor to standing timber in a managed forest, exceeding the combined total of all other factors, including fire, by a wide margin (Massey 1954). A tree that has been attacked by bark beetles usually cannot be saved.

Control by management. - It must be assumed that endemic populations of bark and ambrosia beetles are always present in a forest. Since, under endemic conditions, the beetles breed in unthrifty, injured, broken, wind thrown, or felled material, means must be found to maintain the health and vigor of the
stand if damage is to be reduced or avoided. Vigor might be restored to stagnated young stands by a solution as simple as thimning or to older stands by the removal of overmature trees. In other situations the problem may be much more complex and appropriate action may require extensive knowledge of the ecology and population dynamics of the beetle species as well as of the climate, weather, site, and other factors.

In ponderosa pine forests in western North America, Dendroctonus brevicomis is the principal destructive species. Under endemic conditions it breeds in unthrifty or injured standing trees; it rarely breeds in down material unless it is elevated well above the ground. With this knowledge Keen (1936) analyzed age and vigor tree groups and developed a risk rating technique that made it possible to identify with reasonable accuracy those trees that would be attacked by the beetles (Fig. 5). The removal of the high risk trees in a managed area reduced remarkably both the frequency and intensity of epidemics. Epidemics that followed were triggered by prolonged drought or other uncontrollable factors (Miller and Keen 1960).

Similarly, Dendroctomus pseudotsugae is the principal destructive species in Douglas fir in western North America. Endemic populations breed in broken, wind thrown, or felled trees (Rudinsky 1966). Removal of these susceptible trees generally prevented the development of an epidemic. The habits of D. rufipennis in spruce are apparently similar (Massey and Wygant 1954), and similar results are obtained with sanitation salvage (Schmid 1977).

The removal of potential breeding material from a forest, orchard, or isolated ornamental tree to lessen or eliminate bark or ambrosia beetle attack is applicable to almost any host or geographical situation. The practice in some circumstances may become more effective if the material is allowed to become infested before it is removed. However, in order for this latter technique to be effective, greater knowledge of the habits and behavior of the insects is required and thorough destruction of infested materials must be assured or the intended control could lead to a disastrous epidemic.

Surveys - Losses caused by bark beetles usually involve individual trees or clusters of trees irregularly distributed in the forest. Because forests contain vast acreages of trees from which economic return is minimal, insect surveys are made to locate infestations in their early stages, to appraise their potential destructiveness, and to determine the need for direct control. They are used to diagnose and to predict the economic impact a developing epidemic might have. The results provide information useful in direct control and also contribute to our understanding of these insects in nature.

In evaluating populations it is important to know whether an endemic or an epidemic condition exists and, if epidemic, whether the population is increasing or decreasing. Endemic conditions prevail when natural control factors (climate, weather, predators, parasites, disease) hold the population at a more or less constant level at which damage is normal. Epidemic conditions exist when damage exceeds normal limits. With Dendroctonus brevicomis, endemic losses are those equal to less than annual tree growth, epidemic when losses exceed annual growth.

Bark beetle surveys are of two kinds. First, detection surveys locate potential epidemics or locate newly established foreign species and establish changes in their distributions; accurate identification of the species encountered may be all that is required. Second. evaluation surveys determine (a) the extent and intensity of the infestation, (b) infestation trends, (c) current and expected damage, (d) need for direct control, and (e) effectiveness of direct control. Evaluations are made directly by measuring the quantity and vigor of the beetle population or indirectly by measuring tree mortality or other damage caused by the beetles. Because of the ease with which it is measured, damage has been used much more commonly in the past, but cur rently population trends are considered a more reliable indicator in assessing the need for control. Conditions that trigger epidemics, such as wind throw, are also assessed.

Both aerial and ground surveys may be used. Aerial survevs usually require less time, effort, and expense. They may be made visually or with the aid of photography, using various types of film or lens filters that
accentuate features of dead and inthrifty trees (based on the amount of heat radiated). Aerial surveys are usually supplemented by ground surveys when irregularities or suspected embryonic epidemics are encountered. Aerial photographs may make possible the detection of infested trees not recognizable to the unaided eye that can then be located and examined during a ground survey. They also accelerate the speed and efficieney with which ground surveys can be carried out and provide a permanent record which can be reexamined later.

Direct control.- Most of the bark beetle control applied in American forests is directed at members of the genus Dendroctonus. The first attempt involved $D$. ponderosac in the Black Hills of South Dakota in 1906. Direct control refers to any attempt to reduce populations by artificial means. Its objective is to reduce bark beetle populations to a point where economic damage is reduced or eliminated. It is used as a last resort when natural and cultural control fail.

Surveys provide the biological and economic data on which direct control decisions are based. First, they identify the insect as one capable of posing an economic threat. Second, they determine that the stand is composed of species and age classes that might sustain an epidemic in trees of economic value or that might threaten an adjacent area of economic worth. Third, they determine whether the insect is endemic or epidemic and, if epidemic, whether the trend is up or down. A decision relative to the necessity for direct control and the methods and extent to which it will be carried out are based on these data.

Several methods of direct control have been used successfully to reduce bark beetle poulations. The method selected depends upon (a) the habits of the beetle, (b) the thickness of bark, (c) the size of the infested trees, (d) the height of the infestation, (e) the forest type, (f) the accessibility to roads, and (g) public pressure. These methods include the following (summarized from Rudinsky 1960, 1978).

1. Salrage: Infested trees are felled and removed from the forest before brood matures. To be successful, aceess roads are essential and the infested material must be removed
bevond the flight range of the beetle or else the bark and outer slabs must be treated or destroyed. The expense of a salvage operation usually far exceeds the value of the salvaged timber.
2. Fell, peel, burn: This is the oldest method of direct control. It is still in use in areas where chemical control is not feasible. Infested trees are felled, the upper infested bark is peeled then piled along the trunk and fired. It is used particularly in those species where the brood is not exposed on peeled bark at the time the operation is carried out, such as Dendroctonus brevicomis. The cost of this method is comparatively high ( $\$ 4.40$ per tree for 62,437 trees, according to Keen 1952).
3. Fell, deck, burn: Infested trees are felled, piled in layers that alternate at right angles in direction, then fired. The method is used when infested trees are comparatively small, such as with Dendroctonus ponderosae in lodgepole pine. Care must be taken to position fires in open areas where healthy trees will not be scorched, thereby making them susceptible to beetle attack. It may also be necessary to treat the stumps of felled trees to prevent a population buildup in them. The cost per tree is about half that of the fell, peel, burn method.
4. Oil burning: This method was developed to treat thin-barked standing trees, such as Dendroctonus ponderosac in lodgepole pine. The infested bark on the bole of standing trees is sprayed with slow-burning fuel oil and fired. Because of the limitations of spray equipment, tall trees must be felled for effective treatment of the upper bole. Great care must be exercised to avoid scorching green trees. Careless treatment can precipitate a greater epidemic than the one being treated. Keen (1952) reported the cost of treatment per tree at $\$ 0.68$ to $\$ 1.05$.
5. Pecling: The infested bark of either standing or felled trees is peeled to expose broods to desiccation and to predation by rodents, ants, etc. It is effective only when the brood is exposed on peeled bark, such as with Dendroctonus ponderosae and D. pseudotsugae.
6. Solar-heat: The infested trees are felled, limbs are removed, and the $\log$ is positioned so as to receive maximum radiation from the
sun. In areas where air temperature exceeds 24-26 C (75-78 F), subcortical temperature exceeds 43-51 C (110-123 F), which is lethal to bark beetle larvae (see High Temperature under Hibernation and Estivation, above). Logs must be turned after exposure for several days for the temperature to reach lethal levels on all surfaces. This method was used successfully on Dendroctonus ponderosae on lodgepole pine.
7. Trap trees: Freshly felled or girdled standing trees may attract bark beetles to a treatment area, where their destruction is carried out. This method met with limited success when applied to Dendroctonus rufipennis (Massey and Wygant 1954), but with little or no success with D. brecicomis (Miller and Keen 1960).
8. Drowning: The storing of infested logs in mill ponds has control value if the logs are submerged six weeks or longer then turned so as to submerge the upper area for an additional period of time. The exposed surface may also be treated with a chemical. This method has also been used to prevent infestation of logs by ambrosia beetles.
9. Chemical control: Insecticides applied as sprays in a fuel oil carrier have been used extensively for bark beetle control. Chemicals used include orthodichlorobenzene, benzene hexachloride, ethylene dibromide, and chlorodane. These have been used in various concentrations at the rate of about four fluid ounces per square foot of bark or until the spray begins to run off. They are most effective when air temperatures exceed $16 \mathrm{C}(60$ F). Although chemical control is the most effective and least expensive means of bark and ambrosia beetle control, the chlorinated hydrocarbons used have had an adverse effect on birds and other wildlife, due to biological magnification in the ecosystem. Due to public pressure to conserve the wildlife, their use has declined dramatically.
10. Pheromone traps: Pheromone (sex attractant) traps have been remarkably successful in the control of many insects. Although numerous experiments have been conducted with bark beetle pheromones (with or without tree resins, alcohol, or combinations of
these), successful control has not been achieved. In spite of the failures, it offers great promise of eventual success.

## CLASSIFICATION

## History

Five scolytid species were listed by Linnaeus (1758) in his tenth edition of Systema Naturae, in which the foundation of modern animal classification was established. All were treated in the composite genus Dermestes of the order Coleoptera. Geoffroy (1762) established the first genus (Scolytus) within the group. At that time family-group categories did not exist. Later, when familygroup names were introduced, early writers placed scolytid genera in various groups of Coleoptera, such as Bostrichi or Bostrichidae (Latreille 1804, Erichson 1836), Curculionites or Curculionidae (Latreille 1807), or the nonLinnean Xylophaga (Ratzeburg 1837, Eichhoff 1864). The first valid family-group name involving these insects was Scolytarii (Latreille 1807:273), established as a subdivision of Curculionites and based on Scolytus Geoffroy, 1762. Subsequent authors have subdivided the group into a complex system of subfamilies and tribes (Wood 1978). At the present time approximately 6,000 species of Scolytidae in the world fauna are known; these are distributed among about 181 genera. About one-fourth of the named species occur in North and Central America.

## Taxonomic Position of Scolytidae

The Coleoptera are divided into four suborders, of which the largest and most specialized is the Polyphaga (Crowson 1967). The Polyphaga are subdivided into 18 superfamilies, of which Curculionoidea (formerly designated as the suborder Rhynchophora) is the largest and most highly evolved (Crowson 1967). Within the Curculionoidea the families may be classified by characters summarized in the following key (modified from Crowson 1967).

 (andal aspects, respectively; D F, IIylurgops $r$. rugipenmis (Scolytidace, lateral, candal, and dorsal aspects, reppectisely: (;-H. Ips mexicamus (Scolytidae), ventral amd lateral appects; I, Rhyncolus knoultoni (Cureulionidae), ventral appect: J. (imberis attelaboides (Nemenvehidace, ventral aspect. hutermal head structure is indicated by broken lines, externally visible feature by solid lines. The anterior tentorial ams are not developed in pecies illustrated here. Abbreviatoms: an, antemal msertion or scrobe; aps, apolema! inflection of pregnlar suture; cm, cervical membrane attachment; dat, dorsal arms of tentorime; dim, dorial margin of foramen magmm, is, gular suture; hy, hypostomal arm: mes, median apodeme formed by inflection of gular suture; mep, median tentorial pillar: p. prequla; pap, paired apodemal plates of gular structure: pe, post qula; ps, preqular suture: ptl) posterior tentorial bridge: ptp, posterior tentorial pit; wh. ventral margin of foramen magnam.

## Key to the Families of Curculionoidea

1. Gular sutures (or their rudiments on margin of foramen magnum) widely separated (Fig. 11J); maxillary palpi 4-segmented; antemat never geniculate; larval thoracic spiracle mesothoracic or intersegmental, mandibnar mola sometimes present, $\mathcal{Z}$-segmented thoracic legs sometimes present2

- Gular sutures confluent between small postgula (on margin of foramen madnum) and anterior limits of tentorimm (at angle between ventral surface of head and rostrum) (Figs. 11-12); maxillary palpi 2- or 3-segmented (except Austroplatypus in Platypodidae and Attelabidae); antennae sometimes geniculate; larval thoracic spiracle on prothorax or intersegmental, mola never present, thoracic legs absent (except 1 -segmented in some Brenthidae)6

$2(1)$ Adult labrum distinct and separate; maxillary lacinia distinct, palpi flexible;
larval mandible usually with a mola, thoracic legs present ..... 3

- Adult labrum fused to head, not free: maxilla without a true lacinia, palpi rigid: larval mandible without a mola, thoracic legs absent4
$3(2)$. Tentorium and gular sutures largely to entirely obsolete; pronotum with lateral margins acutely raised; inner surface of elytra near costal margin with a flange; visible abdominal segments $1-4$ connate; larval clypeus distinct from frons or head retracted Anthribidate
- Tentorium present, gular sutures distinct from margin of foramen magnum to posterior tentorial pits (Fig. 11J); lateral margins of pronotum rounded, not marked by an acutely elevated, longitudinal costa; inner surface of elytra near costal margin without a flange; visible abdominal segments freely movable; larval clypeus fused to frons, head never deeply retracted into prothorax
$4(2)$. Inner surface of elytra near costal margin with a flange: gular sutures moderately long to very long; antemnae filiform, inserted some distance from base of rostrum; lateral margins of pronotum rounded; coxae subcontiguous; tarsi pseudotetramerous Belidae
- Inner surface of elytra near costa without a flange; gular sutures very short. not visible with head in normal position; antennae clubbed or if not, then tarsi pseudotrimerous .5

5(4). Antennae chbbed: pronotum with lateral margins acute; tarsi pseudotetramerous, segments 2 and 3 broadly bilobed; rostrum long, antemnae inserted at its base on posteroventral surface . Oxycorynidae

- Antemae not clubbed; tarsi pseudotrimerous, only segment 2 bilobed; rostrum comparatively short, antennae inserted some distance from base on lateral surface . Proterhinidae
6(1). Pregular sutures present, a distinct pregular sclerite between median gular suture and labial articulation (Fig. 11G, ps) rostrum primitively absent .7
Pregular sutures absent, pregular sclerite not evident (Fig. 111): rostrum very
long to secondarily short .......................................................................................... \&
7(6). Tarsal segment 1 as long as 2-5 combined (except shorter in Protoplatypus, Protohylastes, Coptonotus) (Fig. 13); head as wide as pronotum; pronotum usually with a distinct lateral constriction near middle; antennal club without sutures (except obscure in Coptonotus); apical mucro on protibia formed primitively from middle apical process: lateral denticles on protibia never socketed.

Platyponidae

- Tarsal segment 1 not longer than segment 2 or 3 (Fig. 23, etc.); head conspicuously narrower than pronotum, often concealed by pronotum when viewed from dorsal aspect; apical mucro on protibia formed primitively from mesal apical process; lateral denticles on protibia usually socketed $\qquad$ Scolytidae
8(6). Antennae straight, club usually not developed; labial palpi minute, inserted in deep, ventral pits; rostrum often strongly sexually dimorphic; trochanters normal; larval thoracic legs usually present, frontal sutures reaching articulating membrane of mandibles, abdominal segments with three or four tergal folds

Brenthidae

- Antemae clubbed, usually geniculate (if not then trochanters elongate); rostral sexual dimorphism less conspicuous; larval thoracic legs indistinct or absent, if frontal suture reaches articulating membrane of mandible then abdominal segments with only two folds
9(8) Antennae not geniculate, or trochanters long; larval frontal sutures reaching articulating membrane of mandible, abdominal terga with two dorsal folds $\qquad$ Apionidae
- Antennae usually geniculate, trochanters rarely long; larval frontal sutures not reaching articulating membrane of mandibles, abdominal terga with three to four transverse folds

Curculionidae

Fig. 11 continned, parts (; - 1 (-1 redrawn from Wood 1973:79-80).

## Family States of Scolytidae

The Platypodidac and Scolytidae are unique among those curculionoids with one median gular suture in having a pair of distinct pregular sutures that delimit a pregular sclerite immediately behind the oral area on the ventral surface of the head (Fig. 11G). These two families occupy a unique ecological niche as subcortical borers in unthrifty or dying woody plants in which paired (either
monogamous or polygynous) parent adults excavate galleries within a host and together reproduce and defend their brood (at least temporarily) in those tumnels. Largely because larval characters were not found to distinguish these two families from Curculionidae, Crowson (1967) reduced the timehonored families Platypodidae and Scolytidae to subfamilies of Curculionidae. In view of the unique adult gular character and the limited and apparently superficial search for

Fig. 11 continued, part J (Redrawn from Crowson 1967:157).
larval characters, his action is considered untenable. Both groups have been restored to family status (Wood 1973).

The Platypodidae and Scolytidae occupy the same basic ecological niche; the ambrosial habit that is almost universal in Platypodidae has arisen, apparently independently, in 3 of 11 tribes of Hylesininae and in 5 of 14 tribes of Scolytinae. The two groups intergrade anatomically, behaviorally, and ecologically. They are obviously very closely related to one another, but are retained as separate families until their status is more fully investigated.

Various classifications of subfamilies and tribes have been presented for Scolytidae (Wood 1978). Following a review of about 90 percent (412 of 472 nominate genera and subgenera) of the valid genera in the world fauna, 2 subfamilies containing 25 tribes were recognized (Wood 1978). The following key
to subfamilies and tribes of Scolytidae summarizes the characters on which that classification is based.

## Fossil History

Comparatively few fossil Scolytidac are known. Walker (1938) attributed engravings in petrified Triassic wood from Arizona to scolytid beetles designated as Palcoscolytus divergus Walker, Paleoipidus perforatus Walker, and Paleoipidus marginatus Walker. The engravings of Paleoscolytus are too large ( 5 mm wide) and branch in a pattern unknown in modern Scolytidae. The Paleoipidus holes in the wood are not cylindrical; there is no evidence that they were formed by scolytids, but this possibility should not be discarded. However, engravings on Cretaceous coniferous bark from Europe, reported by Brongniart (1877), almost certainly were made by phloeophagous Scolytidae.

Scudder (1876, 1878, 1893) named three scolytids from American Eocene deposits as follows:

Polygraphus wortheni Scudder, Roan Mts.. Colorado

Dryococtes carbonarius Scudder, Green River, Wyoming

Dryocoetes impressus (Scudder), Green River, Wyoming

Schedl (1947) reviews the fossil Scolytidae found in Baltic amber from the Oligocene. The 22 species cited represent the genera Hylastes (1), Hylurgops (5), Hylescierites (2), Xylechinites (1), Carphoborites (2), Phlocosinites (8), Taphramites (2), and Taphrorychus (1). Specimens have been taken in American amber, but have not been reported.

Hopkins (1902a) indicates that Dryocoetes impressus probably is not a scolytid. In addition to the Eocene forms cited above, the following were named (Scudder 1893, Wickham 1913, 1916) from the Florissant Miocene deposits in Colorado:

Phlocotribus zimmermanni Wickham
Leperisinus extractus (Scudder)
Hylurgops piger Wickham
Hylastes americamus Wickhan
Pityophthoridea dilucialis Wickham
Adipocephalus hydropicus Wickham
Xyleborites longipennis Wickham

Fig. 12 A, B. Dendroctonus talens, (A) dorsal and (B) lateral aspects. Present usage of interstriae ( $=$ interspace in this figure), tergum and sternmo ( $=$ tergite, sternite). (After Hopkins 1909:6, 9.

Quaternary fossils of living North American species (age 10,000 years) are reported by Ashworth, Clayton, and Bickley (1972) and Ashworth and Brophy (1972) as follows:

Phloeotribus piceae Swaine
Polygraphus rufipennis (Kirby)
Scolytus piccue (Swaine)
Orthotomicus caelatus (Eichhoff)

Fig. 12 C. Dendroctonus calens, ventral aspect. (After Hopkins 1909:8.)

Ips probably perturbatus (Eichhoff)
Older Quaternary fossils (age 70,000 years) were taken in Ontario by Drs. Alan and Anne Morgan (in prep.) as follows:

Phlocosinus pini Swaine
Phloeotribus piceae Swaine
Carphoborus carri Swaine
Carphoborus andersoni Swaine
Polygraphus rufipennis (Kirby)
Scolytus piceae (Swaine)
Pityogenes or Pityokteines sp.
Pityophthorus probably puberulus (LeConte)

The occurrence of representatives of modern genera of both subfamilies of Scolytidae in the Eocene suggests an earlier origin of the family than has been indicated previously. Fossil evidence coupled with that from biogeography indicates an origin at least as early as the early Cretaceous and perhaps as early as late Triassic.

## Discussion of Characters

Previous classifications of higher categories in the Scolytidae and a more complete dis-
cussion of potential characters and their significance appears in Wood (1978). A brief summary of that discussion is presented here. Characters of greatest use in determining phylogenetic relationships and the limits of the higher categories within the family include the following.

Head. - In curculionids, Hylesininae, and primitive Scolytinae (Scolytini, Ctenophorini, Scolytoplatypini, Carphodicticini) the posterior region of the head is essentially truncate (Fig. 14A). In the remaining Scolytinae, commencing with Micracini and progressing to the Xyleborini and Corthylini, the dorsal occipital area is produced caudad (Fig. 14B). This is an obvious specialization.

The subrostrate condition of Hylastini, Hy lesinini (part), Hyorrhynchini (part), and Scolytini (part) is probably more closely correlated with habit than with phylogeny. Thepregular sutures evidently prevented the development of a rostrum in Platypodidae and Scolytidae, since the anterior arms of the tentorium are intact (they are absent, or at least broken, in curculionids).

The eye varies from oval and entire to elongate and entire or emarginate to

Fig. 13. Tibia and tarsus of Platypus parallelus, posterior face.
completely divided. While eye shape and position are very useful in the recognition of genera, it should be pointed out that some of the most aberrant eve shapes occur in some of the most primitive tribes. In general, however, the oval, entire eye is primitive: departures involving elongation or emargination are specializations.

The antennal funicle may have a maximum of seven segments as in other curculionoids. Within Scolytidae the segmentation may be reduced to as few as three segments in Hylesininae or one in Scolytinae. Reduction in the number of segments from seven is considered as specialization.

The antennal club is formed from three segments. In primitive scolytids, as in many other curculionoids, it is conical (Hylastini, some Hylesinini). Specializations may include compression (flat) or oblique truncation, either with or without the loss of sutures. The club may be symmetrical or asymmetrical, with the sutures equal on both sides or with the sutures on the posterior face strongly displaced toward the apex. In Phloeotribini the intersegmental lines are constricted, thereby forming a sublamellate club with independently movable segments.

Prothomax. - The primitive prothorax apparently was short and more or less cylindrical. Spectializations include a substantial reduction in the sternal areas accompanied by a change from widely separated to contiguous coxae. A precoxal costa was associated with that change in some primitive groups. The dorsal area in specialized groups is declivitous on the anterior area, armed by asperities, and much narrower anteriorly. In Diamerini, Bothrosternini (part), Scolytini, and Ctenophorini the lateral margin of the
pronotum is costate. This costa appears to be a strengthening device associated with a subconcave pleuron in these comparatively primitive tribes. An analogous raised line in Cryphalini and Corthylini apparently has a different origin and function.

Mesothorax, elytra.- While numerous characters of specific and generic interest occur on the mesothorax, items of phylogenetic interest involve the basal margins, interstriae 10, and the mechanism for locking the elytra in position when at rest.

In all Hylesininae the basal margin of each elytron is procurved and armed by a series of crenulations. The curvature results from a sutural emargination formed to accommodate the depressed, rounded scutellum. The crenulations are shared by a few speeies of Cnemo$n y x$ (Scolytini), but otherwise are restricted to the Hylesininae. A few Diamerini and Bothrosternini have an elevated marginal costa in place of the crenulations. In Scolytinae the elytral bases form a straight transverse line across the body and the scutellum is large, flat, and flush with the surface.

Most primitive tribes contain at least some members having interstriae 10 continued to the apex. In more specialized groups striae 9 and 10 converge near the middle of the elytra, thus eliminating the posterior half of interstriae 10 .

On the sutural and costal margins of the elytra near the base are grooves that interlock at the suture with the opposite elytron and on the costal margin with the metepisternum. The details of these structures are useful in determining phyletic relationships of major groups.

Metathorax, tergum.- In some Hylesininae (Diamerini, Bothrosternini, Phloeotribini, Phloeosininae, Hypoborini, Polygraphini) the scutellar area of the metanotum fuses with the postnotim, thus eliminating the intersogmental suture. The intersegmental suture is present in the remaining Hylesininae and in all Scolytinae. In addition, the scutoscutellar suture follows a much shorter, more lateral route in those groups with a fused postnotum. These two characters make possible a major division of the Hylesininae.

Metathorax, pleuron.- In Curculionidae, primitive Hylesininae, and primitive

Fig. 14. A, Hylastes nigrinus, lateral aspect of head; note, eye, antenna, and undeveloped dorsal occupital area (Left side near middle of foramen magnum damaged in preparation). B, Ips woodi, ventrolateral aspect of head: note postgula, gular suture, pregula, and extended dorsal occipital area.

Scolytinae the pleural suture descends vertically from the pleural wing process to the groove on the episternum that receives the costal groove of the elytra. At that point the pleural suture turns abruptly and follows the groove caudad to near the pleural coxal process. The anterior end of the lower costa that forms the metepisternal groove is higher, often spinelike, and may persist when the remainder of the groove is lost. In the higher Hylesininae and higher Scolytinae the groove is lost, the episternal spine is displaced ventrad, and the pleural suture runs a much more direct route from wing process to coxal process, often quite remote from the position of the costal margin of the elytra. In Cryphalini the episternal spine is modified and in Corthylini it is lost and replaced by a small, transverse groove.

Legs. - Tibial characters have been used extensively in scolytid classification. The primitive protibial form is thought to be similar to that of Protohylastes (Fig. 35), which has three apical spines (Wood 1973a). The small mesal spine apparently becomes the apical spine of Scolytidae; the larger, middle spine becomes the apical spine of Platypodidae and the major lateral spine of Scolytini, etc.; and the smaller, lateral spine becomes a minor lateral spine in all groups. These spines, and some supernumerary denticles, are not socketed (Fig. 29). All these lateral spines
are replaced by socketed teeth (Fig. 34), presumed to be of setal origin, in all higher groups (Wood I978).

In several of the more primitive groups tarsal segment 3 is broad or bilobed. In Diamerini (part), Xyleborini (part), and Xyloctonini the tarsi tend to be laterally compressed and retracile into tibial grooves. The tarsal characters are of some value in classifying genera of certain tribes.

Abdomen.- In Carphodicticini, Ipini, Dryocoetini, Xyleborini, and all Platypodidae female abdominal tergum 8 is visible, pubescent, and almost as large as in the male. In all other scolytids and most curculionids it is of reduced size, lacks pubescence, and is telescoped beneath and hidden by tergum 7 (Fig. $14 \mathrm{C})$.

In Hylastini, many Hylesinini, and Phloeotribini the posterior margin of mate tergum 7 bears a median, bituberculate, stridulatory device that scrapes against the adjacent imer surface of the elytra. The value of this character is uncertain, it is not alwavs present in groups that normally possess it. It may be significant that a comparable character occurs in most Platypodidae.

## Phylogeny

The Scolytidae and Platypodidae apparently arose as a monophyletic unit from the

Fig. 14C. Abdominal terga of Cryphalus pubescens: Male, segments 7 and 8 (above); female, segment 7 (below). (After Wood 1954:1087.)
segment of the Curculionoidea having one gular suture before pregular sutures were lost in the remainder of the phyletic line that gave rise to the Brenthidae, Attelabidae, Apionidae, and Curculionidae, but well after the groups having two gular sutures, or remnants of them (Belidade, Nemonychidae, Anthribidae), had branched from the main stem of evolutionary development. Long after the basic scolytid-platypodid characters and habits had been fixed, this evolutionary line radiated into three groups at approximately the same geologic time (possibly late Triassic to early Cretaceous). These three groups presently include representatives among their primitive tribes having (1) a 7 -segmented antennal funicle, (2) a fully formed, pub-
escent female tergum 8 basically similar to that of the male, (3) basically similar tibiae that lack socketed supernumerary spines on the lateral margins, (4) a fully developed interstriae 10 , (5) the same general body habitus, and (6) the phloeophagous habit. The evidence is inconclusive as to which of these three groups branched from the main scolytoid evolutionary stem first; however, because of the somewhat larger number of primitive characters and the different appearance (probably related as much to distinctive habits as to genetics), coupled with unique specializations, the Platypodidae are regarded as the most primitive. For similar reasons the Hylesininae are considered to be more primitive than the Scolytinae, but the genetic relationship between primitive Platypodidae and primitive Scolytinae may be closer than either of these is to the Hylesininae. The Scolytinae are considered to represent the main line of scolytid evolution. The accompanying dendrogram (Fig. 15) illustrates possible phylogenetic relationships of major groups within these families.

The most primitive known representative having hylesinine characters is Protohylastes. It could equally well be placed as the most primitive representative of Platypodidae (Coptonotinae). It shares many characters with Coptonotus. Except for the antennal club and tibiae, it could be placed in the Hy lastini with complete confidence. It is placed as an aberrant genus of Coptonotini until more can be learned about its structure and habits.

Platypodidae.- The pregular sutures, numerous other structural details, and the shared ecological niche suggest a close relationship to the Scolytidae. The 7 -segmented funicle (Protohylastes and Coptonotus), strongly procurved antennal sutures (Coptonotus), fully developed female abdominal tergum 8, complete interstriae 10 , route followed by the scutoscutellar suture, route followed by the metapleural suture, tibial characters, elytral locking mechanism, the polygynous habit in Protoplatypus, and other characters indicate a closer, but very primitive, connection to Scolytinae rather than to Hylesininae. The closest affinity of Platypo-

Fig. 15. Dendrogram illustrating possible phylogenetic relationships of major groups within the Scolytidae and Platypodidae.
didae (through Protohylastes) to Hylesininae appears to be through Diamerus (Diamerini), which possesses several very specialized features. The closest affinity (through Protoplatypus) to Scolytinae appears to be through Cnemonyx (Scolytini), Scolytodes (Ctenophorini), Carphodicticini, and Scolytoplatypodini.

Hylesininae.- The fusion of the metanotum to its postnotum apparently took place very early in hylesinine evolution as evidenced by the occurrence of tibiae without socketed teeth in both divisions (Hyorrhychini, Diamerini, and Phloeotribini). More primitive characters, with fewer specialized ones, appear to be associated with Hylastini, Hylesinini, and Tomicini (listed in increasing
order of specialization), with the Phrixosomini and Hyorrhychini representing specialized relicts of otherwise primitive groups.

In the more specialized hylesinine line are found the more primitive tibiae (Diamerus, Aricerus), pronotums (Diamerus), elytral bases (Bothrosternini, Diamerus), and other characters, but they also exhibit the greatest specializations (reduced funicular segmentation, aberrant antennal club with loss of sutures, etc.). The fusion of the postnotum obviously took place very early in hylesinine evolution, as evidenced in that group by the much greater structural and biological diversity. The Diamerini and Bothrosternini, which appear to be geographical replacements of one another, share the greatest number of primitive features; they also appear to
have diverged further than the other groups from the original ancestral line. The Phloeotribini also diverged rather early as evidenced by the protibia of Aricerus and by the very different, sublamellate, antemal club. The Hypoborini and Polygraphini appear to be specializations that diverged rather recently from the Phloeosinini.

Scolytinae.- The basic structural relationship of most Scolytinae to Platypodidae is closer than to Hylesininae, although the biological affinity is closer to most Hylesininae. The strongly procurved antemal sutures of Coptonotus (and the obscure lines that suggest obsolete sutures in other Coptonotinae and a few Platypodinae) is a common character in Scolytinae (Scolytini, Ctenophorini, Micracini, Xyloctonini), but occurs only in Diamerini (Diamerns) and Bothrosternini (Pagiocerus, Eupagiocerus) in the Hylesininae. The Scolytini apparently diverged very early from the main evolutionary line in Scolytinae, as evidenced by antennal, tibial, metaplewal, and other characters. The divergence of Scolytoplatypodini and Ctenophorini soon followed, as evidenced by a significant change in tibial characters, and these geographical replacements then diverged from one another. The remaining Scolytinae replace unsocketed lateral tibial spines with socketed teeth that apparently were derived from setae. Except for the socketed tibial teeth, Carphodicticini most nearly resembles my concept of a primitive platypodid in antennal, frontal, pronotal, coxal, metapleural, metatergal, and abdominal characters. However, the tibiae, and other characters, place it more nearly intermediate between Protoplatypus and Dryocoetini. The Crypturgini, Dryococtini, Ipini, Xyloterini, and Xyleborini represent a unit of closely related tribes. Micracini and Cactopinini appear somewhat related, as do Xyloctonini and Cryphalini. The relationship of Corthylini to other tribes is not clear; they exhibit some very primitive features as well as many of the most specialized ones in the family.

## BIOGEOGRAPHY

## Extraterritorial Affinities

To establish a basis for this discussion, it is assumed that the following hypotheses and
theories are essentially correct: (1) the biological species concept (Mayr 1963) is valid, (2) biological speciation occurs through a process of geographical isolation, during which time isolated populations of a parent species differentiate and become reproductively isolated from one another (Mayr 1963), and (3) a process of continental drift has occurred that has had an effect on the geographical distribution of animal groups (Wegener 1924). It is also necessary to eliminate from this discussion those species and genera that are known to have been introduced to or exported from North and Central America through modern human commerce (Wood 1977). Most notable in this regard are the imported genera Hylastinus, Hypocryphalus, and Premnobius, and the exportation of Gnathotrichus materiarius (Fitch) to France and Microborus boops Blandford to Africa.

An analysis of the tribal groups of Scolytidae reveals the following relationships (Tables 1,2 ). The Cactopinini are found only in southwestern North America. The Bothrosternini and Ctenophorini are restricted to the tropics of North and South America; Scolytini (except Scolytus extends to Eurasia) and Corthylini (except Pityophthorus extends to Eurasia; there are also a few aberrant African forms) are almost exclusively American. Phloeotribini are largely American, with a few species of Phlocotribus in Eurasia, except that the monotypic Aricerus appears to have reached Australia very early in the formation of the group. The Polvgraphini, Crypturgini, and Xyloterini are of obvious Eurasian origin and reached northern North America rather recently. The Hylastini, Hylesinini (except Phlocoborus that was derived biogeographically from South America), and Ipini (except Acanthotomicus, which probably reached South America from Africa in pre-Tertiary time) are also of Eurasian origin, but the involvement appears much older and more complex. The Phrixosomini, Hypoborini, and Micracini apparently reached North and Central America rather recently from South America, but exhibit a strong, much earlier relationship to the African fauna. The Tomicini, Phloeosinini, Dryocoetini, Xyleborini, and Cryphalini are diverse and indicate more complex endemic origins and interrelationships with other areas. The Hyorrhynchini, Diamerini, Scolytoplatypodini,

Carphodicticini, and Xyloctonini do not occur in North America, although two of three genera of Carphodicticini occur in South America and Diamerini (Old World) appears to replace geographically Bothrosternini, and Scolytoplatypodini (Old World) replaces Ctenophorini.

The principle original centers of adaptive radiation in the family appear to be North America for Hylastini, Tomicini, and Cactopinini; South America for Phrixosomini (and Africa), Bothrosternini, Phloeotribini, Scolytini, Ctenophorini, Micracini (and Africa), and Corthylini; Eurasia for Hylesinini (and Africa, except South America for Phloeoborus), Phloeosinini (and Africa), Ipini (and Africa), Xyloterini, and Cryphalini (and Africa); Africa for Hypoborini, Polygraphini, Crypturgini, and Dryocoetini. The radiation of Xyleborini has progressed explosively from the Tropics, but the pattern is not yet clear.

Secondary radiations of each tribal group may also occur in newly occupied areas. For example, the Ipini apparently originated in tropical Africa as the precursors of Acanthotomicus then spread northward into Eurasia, giving rise to a new stock. The portion of the new stock that remained in Eurasia apparently gave rise to Orthotomicus and Pityogenes, and the portion that reached North America gave rise to $I p s$ and Pityokteines. Later, elements of Orthotomicus and Pityogenes reached North America and elements of Ips and Pityokteines reached (or returned to) Eurasia to give rise to the present faunas. This is based on the fact that, of nine species groups of Ips in North America, six are shared with Eurasia; no unique group occurs in Eurasia. Similarly, in Pityokteines only one of three groups reached Eurasia, in Orthotomicus only one of several groups reached

North America, and in Pityogenes only three of several groups reached North America.

Comparable multiple migrations appear to have affected several other groups with equal magnitude when faunal transfers were sufficiently early to permit secondary radiations. In some instances the migrations were so recent that speciation of the populations on different continental land masses may not yet be complete.

The faunal connection (over the Bering land bridge) between North America (Alaska) and Asia (Chukchi Peninsula) appears to be recent. This is indicated by the occurrence in both areas of identical or very similar species of Scolytidae, particularly those that breed in Picea. For example, Dryococtes autographus and Trypodendron lineatum occupy both areas and apparently have not speciated. In the following series of names speciation is evidently complete, although the members of each pair are so similar to one another that identification is difficult.

| Hy/urgopes rugipemmis | II. glabratus |
| Polygraphus rufipernis | P. poligraphas |
| Dendroctonus punctutus | D. micans |
| Hylastes nigrimas | H. cmicularius |
| Xighechimus ammericamus | 入. pilosus |
| Polygraphus comexifrons | I. grambliclata |
| Phlocotribus piceede | P. spimulosus |
| lis. perturhatus | 1. typogrciphus |
| Crypturgus borcalis | C. tuberostes |
| Dryococtes affaber | D. pini |
| Cryphalus rulicollis | C. asperatus |

Of the 24 American species occurring in Picea north of the 60th parallel, I have established a definite phenotypic relationship to

Asian species for 13 of them. Adequate material for comparison was not available for 7 of the remaining 11; the other 4 have no Asian counterpart (Scierus annectens LeConte, Dendroctonus rufipennis Kirby, Ips tridens Mannerheim, and I. borealis Swaine). A comparison of species from other hosts and from more southern areas is somewhat less dramatic, but indicates a clear faunal relationship. Sixteen American genera contain species groups, all of which are represented in a more diverse Eurasian fauna; therefore, it is concluded that all species in these genera were derived directly or indirectly (through subsequent speciation) from Eurasia. These genera include:

| Phloensinus (extensive | Cryphalus |
| :--- | :--- |
| secondary 'peciation) | Dolurgus |
| Mylesinus | (not now in |
| Pohygraphus | Eurasia) |
| Carphohorus | Crypturgus |
| Trypophloeus | Lymantor |
| Ernoporus | Dryococtes |
| Pityogenes | Trypodendron |
| Orthotomicus | Xyhotcrinus |
| Procryphahs | (not now in |
|  | Eurasia) |

Both Dolurgus and Xyloterinus are monotypic and endemic to North America, but they were undoubtedly derived from a Eurasian source in that no potential ancestor or near relative exists in the Western Hemisphere. Nine genera are much more diverse in North America, and all Eurasian species groups in these genera are represented in America; consequently, it is concluded that all Eurasian species in these genera were derived directly or indirectly from North America. These genera include:

| Hylurgops | Scolytus |
| :--- | :--- |
| Hylastes | Pityokteines |
| Xylechinus | Ips |
| Dendroctonus | Pityophthorus |
| Phloeotribus |  |

A southern faunal association is more difficult to demonstrate, presumably because potential land connections occurred much earlier in geologic time and many more species are involved. However, several groups, represented only in tropical America and tropical Africa, suggest shared genetic traits. Phrixosoma and Cladoctonus appear to be very old, compact genera with no closely allied living relatives. Both are represented in both areas by several species that are so similar it is sometimes difficult to distinguish an American from an African species; yet potential hosts for these genera abound in other tropical areas where these beetles do not occur. Basically the same is true of Acanthotomicus and Hypothenemus, although they are also represented in the Indomalayan-Australian region. Paired, but different, genera also occur in tropical America and Africa in the Micracini and Hypoborini, and between Dendrocranulus and Xylocleptes. In addition, the Ctenophorini (American) and Scolytoplatypodini (African) replace one another, as do the Bothrosternini (American) and Diamerini (African, etc.) and a few species groups within the Xyleborus.

The above discussion calls attention to a faunal exchange between North America and Eurasia sufficiently recent that speciation apparently is either not complete or that permits easy recognition of species or species groups on both sides of the Bering Strait. This route of faunal interchange was open to arctic and subarctic species at several times during the Pleistocene until quite recently in
geologic time. However, forests were climatically stratified much as at present and it is probable that the only species exposed to the Bering land bridges during Pleistocene interglacial periods were those associated with the northern coniferous forest, namely Hylurgops, Hylastes, Xylechinus, a few Phloeotribus, Polygraphus, a few Scolytus, Trypophloeus, Procryphalus, Cryphalus, Crypturgus, Dryocoetes, Pityoktcines, Pityogenes, Orthotomicus, Ips, Trypodendron, and Pityophthorus. For the most part, the speciation that followed migration of these species has been comparatively minor and species groups on both sides of the Bering Strait are easily recognized. Because the temperate forests have not reached arctic regions since late in the Tertiary, it must be assumed that species dependent on such hosts must have crossed the Bering land bridge during the Tertiary. It is probable that most Phloeosinus, Hylesinus, most Scolytus, Ernoporus, Dolurgus (or its ancestor), Lymantor, Xyloterinus (or its ancestor), and others, are in this category.

Known fossils not only confirm part of the above speculation, but place several genera in invaded territory much earlier than had been supposed. These records include the following (asterisks are used to identify genera invading new territory distinct from the continent of probable ancestral origin; extinct genera were omitted):

Baltic Amber (Oligocene) North America
${ }^{\circ}$ Hylurgops Hylurgops (Miocene)
${ }^{\circ}$ Hylastes $\quad$ Hylastes (Miocene)
Hylurgus (endemic) ${ }^{\circ}$ Hylesinus (Eocene)
Tomicus (endemic) ${ }^{\circ}$ Phlocosinus (Pleistocene)
${ }^{\circ}$ Nylechinus. Phloeotribus (Miocene)
Hylesinus
Phlocosinus
Polygraphus
Carphohorus
Cryphalus
Taphrorychus (endemic)
It is curious to note from the above that Tomicus was present in Europe in the Oligocene, but it has never become established in North America even though a route for migration has been open and breeding specimens have been intercepted here on several occasions during the past century (Chamberlin 1939:215-216). It is also curious that Dendroctonus is not represented in the fossil
record nor has it invaded Eurasia until very recently ( $D$. armandi may be an exception). In addition, 11 of the existing 20 tribes of North American Scolytidae are represented in the fossil record by modern genera. Seven of the nine tribes not represented are of tropical distribution or were probably too rare in temperate North America for one to expect fossilization.

Because the apparent connection between southern South America and southern Africa was broken by continental drift no later than early Tertiary (most geologists place it 15-30 million years earlier), I had presumed that the availability of such a route for migration would not be reflected in the living scolytid fauna. This is not the case. The above fossil record lists 12 modern genera that are 30 million or more years old in five different tribes. Furthermore, it is noted that, among groups now restricted basically to the American tropics and Africa, the genera Phrixosoma, Cladoctonus, Micracis, Acanthotomicus, certain Hypothenemus, and certain Xyleborus groups, the paired but different genera in the Phloeosinini, Hypoborini, Micracini, and in the Dendrocranulus group of genera of Dryocoetini, the paired but different tribal groups Bothrosternini and Diamerini, and the Ctenophorini and Scolytoplatypodini suggest that such a connection did exist and that the basic patterns of scolytid phylogeny were established long before that land comnection was severed.

Based partly on the above dates and diversity, one might speculate that the Scolytidae originated in conjunction with the origin of coniferous gymnosperms perhaps as early as the Triassic, when conifers were a dominant plant group. In fact, Walker (1938) named Paleoscolytus and Paleoipidus from holes and engravings in petrified Arancarioxylon wood from the Triassic (Chinle formation) of Arizona. Whether or not these were made by scolytids or their ancestors is open to question.

## American Biogeography

Pleistocene glaciation affected the distribution of Scolytidae in northern North America by causing extinction in some areas and providing refugia in others. For example,

Carphoborus andersoni Swaine is common in interglacial lake deposits in Ontario (Morgan, pers. comm.), but presently does not occur south or east of the Northwest Territories. Similarly, C. carri Swaine was common in postglacial deposits in western New York; this species presently is known from Manitoba and New Brunswick, but not from the intervening area.

The present land bridge connecting North and South America has facilitated a faunal exchange between these areas. South America was an island during much of the Tertiary, but was connected to North America at the beginning and again at the end of that period (Darlington 1965). During the Pleistocene this land bridge formed and broke several times. In those periods when the land bridge was broken, a series of islands persisted and preserved much of the fauna that had migrated to them while the connection was complete. Many of these species had either migrated along mountain chains or adapted to the higher elevations on the islands, where they either preserved migrating populations or were modified through selection into new geographical races or distinct species. The groups most conspicuously restricted to high altitudes and affected by the "island" effect are the tropical Xylechinus, Gymnochilus, Chramesus, Stegomerus, Dendroterus, Pseudopityophthorus, the xylomycetophagous Corthylini, and some Cnesinus. The island effect also may have halted the southward migration of the conifers, and all scolytids utilizing them as hosts, in northwestern Nicaragita. The speciation that resulted from the island effect combined with the later migration of the Bothrosternini (except some Cnesinus), Dendrosinus, Phrixosoma, Phloeoborus, Phlocotribus, most Scolytini (except some Scolytus), most Ctenopherini, many Hypothenemus, and Xyleborus in the lowland areas produced a rich fauna that appears unequaled elsewhere in the world in an area of similar size. Considerably more collecting and study must precede a detailed analysis of the scolytid biogeography of this area.

The most distinctive faunal area in North America appears to be the desert platean region from southern California, southern Arizona, and southwestern New Mexico to the Isthmus of Tehuantepec. A considerable
amount of endemism is evident here in the Micracini, Cactopinini, Dendroterus, Pityophthorus, and, perhaps, in several other phloeophagous Corthylini. Superimposed upon this desert plateau are those species that breed in conifers in the mountains that traverse the area and those that penetrate the moist lowland pockets of tropical forest on the margins of the desert region.

Because 39 percent of all North and Central American Scolytidae are known only from their type series, and because most of these species are from Mexico to Nicaragua, a useful analysis of the biogeography of this area is not possible at the present time.

In view of the faunal exchange that has taken place between North America and Asia, both geologically recent and ancient, it appears significant that only two species of Dendroctonus have reached Eurasia, and one of those in comparatively recent times. The high concentration of species and diversity in Mexico suggests a Mexican origin of Dendroctonus, with a comparatively recent invasion of north temperate areas. This possibility is supported by the fact that no endemic Ips species, which share the same hosts with Dendroctonus, have developed in Mexico. All Mexican Ips have distributions extending into the United States. Only four of I6 American species of Dendroctonus presently do not occur in the Mexican plateau area, and all four are of recent origin (one of these is in Guatemala). Pityoborus, Gnathotrichus, Conophthorus, and several Pityophthorus exhibited similar patterns of distribution; for the most part, all breed in Pinus.

The southeastern deciduous forest forms a distinctive faunal area. As evidenced by present relict refugia on the eastern margins of the Mexican plateau, this area formerly extended southwestward into Mexico. Several Thysanoes, Cnesinus strigicollis LeConte, and Micracis swainei Blackman have present distributions that follow this pattern. A few forms that apparently originated in this area, such as Micracisella nanula (LeConte), M. opacithorax, and M. hondurensis Wood, have been modified by speciation. If the pines of the southeastern United States are considered to be part of the deciduous forest, Dendroctonus frontalis Zimmermann and the Ips that
infest those pines and extend into Mexico are another example of this faunal connection.

Southern Florida is distinctive and appears to be more nearly like Cuba or other Antilles Islands than like the southeastern United States in its scolytid fama. A majority of the species appear to have reached the area recently by crossing over water naturally (flotation, wind, etc.) or through commerce. A high percentage of the imported species are first detected in North America in southern Florida.

The scolytid fauna of the northern coniferous forest is distinctive. For the most part, it is rather monotonous but exhibits some endemism due to apparent refugia of past glacial periods in Alaska and Nova Scotia. Elements of this fauna extend southward along the mountains of the eastern and western United States.

The Pacific Coast belt from Alaska to southern California contains a rich fauna with many endemic species particularly in Phloeosinus, Carphoborus, Alniphagus, and Scolytus. From this area many species appear to have migrated since the last period of glaciation into the mountains of Idaho, Wyoming, Utah, Colorado, New Mexico, and northern Arizona. Others, namely some Phloeosinus, Pseudopityophthorus agrifoliae Blackman, and Monarthrum dentigerum (LeConte) have spread into Arizona at a time when the level of precipitation was higher than at present.

## Origin of Tribes

In view of the above summary of data relating to the biogeography of American Scolytidae, perhaps some speculation as to the origin of major groups in the world fauna within the family is in order. This is based on the assumption that (1) a geologically recent Bering connection existed between Alaska and Siberia on more than one occasion, (2) Africa and South America were connected or at least were close enough to permit migration by flight until the early Tertiary, and (3) South America was an island during most of the Tertiary, but was connected to North America near the begimning and near the end of that period and at one or more subsequent times.

Phrixosomini, Hypoborini, Micracini, Dendrocramulus (Dryocoetini), Acanthotomicus (Ipini), and parts of Xyleborini and Cryphalini evidently originated in the African-South American land mass before separation. Phrixosoma was probably then a relict genus rigidly adapted to the Guttiferae and has remained virtually unchanged in both areas since the separation. Micracini had diversified and the basic structure of most genera was almost fixed, as evidenced by paired or identical genera in both areas; diversification of the American segment of this group has been more extensive since the separation. Ctenophorini apparently also had a preseparation origin, but the African segment became modified into modern Scolytoplatypodini largely through the adoption of the ambrosial habit and then dispersed as far as Japan and Australia. The Diamerini-Bothrosternini may have had a preseparation origin, but both diverged and diversified. Phloeotribini, Scolytini, and Corthylini appear to have a postseparation South American origin: all appear to have spread into North America at the beginning of the Tertiary and from there into Eurasia after the Tertiary. An early representative of Phłocotribini reached Australia, apparently from southern South America, possibly either by island hopping or flotation, resulting in the monotypic Aricerus. At a much later date Phlocotribus invaded North America and from there it reached Eurasia. The occurrence of Pityophthorus (including aberrant allied forms) in Africa may indicate a slightly earlier origin for Corthylini; this group probably reached North America by early Tertiary and Eurasia by late Tertiary. Phloeosinini may also have originated in the AfricanSouth American area but subsequent dispersion has obscured the pattern.

Because of repeated and recent connections to adjacent areas, the role of North America in the origin of tribal groups is uncertain, although it has played a significant role in the formation of generic groups within several tribes. A possible North American origin of Hylastini in the remote past is suggested but not clear.

The role of Eurasia, the Indian subcontiment, and Africa (in addition to that mentioned above) is also unclear. The

Polygraphini, Xyloterini, and Crypturgini probably originated in this area after the separation of Africa and South America, or at least dispersal into South America did not occur if there was a connection. The dispersal of Hylesinini, Tomicini, and Hypoborini, and many Dryocoetini, Xyleborini, and Cryphalini is too complex to permit speculation as to origin.

The representation of Hylesinini in North America is largely restricted to Hylesinus and Alniphagus; both genera occur in adjacent Asia and are obvious rather recent additions to the North American fauma. Hylesinini is represented in Central and South America only by Phloeoborus, which is of ancient origin and may be allied to the African Dactylipalpus. Hylastinus was introduced through commerce from Europe within the past century.

Most of the Tomicini are restricted to hosts in the Pinaceae; consequently, their phyletic history is closely linked to that group. Exceptions include Xylechinus (part) (almost worldwide), Hylurgopinus (North American), and Dendrotrupes (New Zealand). This appears to be a declining group that has undergone at least two radiations and is difficuit to interpret.

Except for Phlocosinus, the Phloeosinini consist of the essentially Neotropical Carphotoreus, Dendrosinus, Chramesus, and Pseudochramesus, the Ethiopian Chilodendron, Hylesinopsis, and Trypographus, with Cladoctomus occupying both Ethiopian and Neotropical areas, the Oriental Phlococranus, and the Australian Hyleops. Little relationship is seen in the group of genera from one continent when compared to the group from another continent. Phlocosinus, however, appears to be of south Asian origin and to have invaded Eurasia, North America, and Australia perhaps as early as the early Tertiary.

Except for the almost pantropical Acanthotomicus, it appears that Ipini originated (from Acanthotomicus?) in southern Eurasia or Africa. The early stock invaded North America from the north, where Pityokteines and Ips formed while Pityogenes and Orthotomicus formed in Eurasia. One or more recent connections between the land masses enabled elements of each of these four genera to invade the territory of the other. In each case
the invaded area contains only a minor fraction of the species-groups, all of which are found in the area of origin (see also Extraterritorial Affinities, above).

The Dryocoetini consist of several elements, most of which are of south Asian origin. Exceptions include Dryocoetes (sensu strictu) and Lymantor, which invaded northem North America recently, and Dendrocramulus, which recently invaded southern North America from South America, and Thamnurgus, Xylocleptes, Triotemnus, and possibly Tiarophorus of Eurasia and Africa. The origin of these latter groups evidently predates the separation of Africa and South America sufficiently that ancestral Dendrocranulus, which is almost congeneric with Xylocleptes, could disperse into South America.

The Cryphalini appear to have subdivided early into the Cryphalus group of genera that radiated out from southern Asia and reached northern North America rather recently and the Hypothenemus group of genera that radiated out from the African-South American land mass. A large number of genera and species are involved and cannot be adequately analyzed without a thorough taxonomic study.

## METHODS

Several departures from normal procedure were followed in this study. Those relating to the examination of specimens include: (1) Early in this study it was learned that the published records of distribution and host could not be relied upon as being authentic. Consequently, virtually every record cited in this work was based upon my personal examination of voucher specimens and types. Exceptions are clearly indicated. Almost all existing primary types, including the types of genera, have been examined by me and compared directly in detail to material from the same or a nearby locality. All type comparisons are cited. Due to misidentification, numerous published distribution and host records are not cited because they do not pertain to the species mentioned in the literature. Numerous collections were visited during the course of this study to obtain data and to examine type and other material.

These included the National Museum of Natural History (Smithsonian Institution), American Museum of Natural History, Museum of Comparative Zoology, Illinois Natural History Survey Collection, Ohio State University Collection, State University of New York, Syracuse, Oregon State University, University of California at Berkeley, Colorado State University, California Academy of Sciences, the USDA Forest Service Collections (at Corvallis, Oregon; Berkeley, California; Albuquerque, New Mexico; and Fort Collins, Colorado), Canadian National Collection of Insects at Ottawa, British Museum (Natural History) at London, Museum National d'Histoire Naturelle at Paris, Universitates Zoologiska Museum at Helsinki, Zoological Institute of the USSR at Moscow, Forest Research Institute at Dehra Dun (India), and the Karl E. Schedl Collection at Lienz, Austria. Type and other material was sent by mail for my examination from numerous institutions and private individuals. Because many of these asked to remain anonymous, none are mentioned here. In all, more than 187,000 North and Central American specimens were examined during the course of the study.
(2) Measurements of the length of specimens depart from the usual method in that the head was not included for any species (other workers have included the head for Hylesininae and Scolytini). In general, measurements of the body, pronotum, and elytra were made from a position perpendicular to the dorsal (discal) surface at a position near the middle of the object being measured.
(3) All proportions were standardized; that is, the width was always divided into the length of the body, pronotum, or elytra (others have divided the shorter into the longer measurement regardless of the result).
(4) Insofar as practical, the descriptions were standardized to make comparisons easier and to avoid the illusion of describing differences when, in fact, none exist.
(5) Distributions are presented just in a brief summary that outlines the most distantly separated limits of range. This is then followed by a listing of political subdivisions from north to south beginning with Alaska (listed as though it were a separate country. due to its geographical position) to Panama.

Subdivisions of these political areas are listed alphabetically. When 10 or fewer collection records are known the full data are given; when 10 to 100 collection sites are known the towns or other localities are listed by states, estados, or provinces; when more than 100 sites are known only the names of the states, estados, or provinces are listed.
(6) The authenticity of the data depends on the accuracy of locality, host identification, and labeling by the original collector; on the correctness of labeling in the laboratory; and on the absence of remounting errors and other aecidents that can happen in the curation of collections. Many errors have been published in the literature; a few of these were detected and eliminated or pointed out in this study.

All my studies were made with a stereoscopic American Optical Company microscope at magnifications of $10,40,80$, and 160 X , equipped with an ocular grid, using an American Optical Company illuminator Model 350, except at Moscow and Helsinki, where local museum equipment was used. Measurements were made in millimeters using the ofular grid, only at 10 X magnification, because distortion affected measurements at higher magnifications. Measurements of proportions not requiring conversion to millimeters were made at other magnifications also.

When this study commenced it was intended that a complete listing of all known references to each speeies would be included. However, midway through the project financial support for this activity was withdrawn and the literature review was discontimued. It is hoped that future events will permit the publication of this important omission. Only the original validation of each nominate species and the eitation of new synonymy were included.

My usage of the terms "interspace" and "interstriae" are not synonymous, as is the case with many coleopterists. Interspace here is a generic (general) term referring to a space between two objects, such as the space between any two punctures on the frons, pronotum, or elytra. Interstriae is restricted to the space on the elytra between two strial rows. Because the space referred to can exist only between two striae, only the plural form
of this term is valid. An interstriae is an interspace, but only one restricted usage of interspace is an interstriae. To avoid confusion in this work, an interstriae is never referred to as an interspace.

## SYSTEMATIC SECTION

## Family Scolytidae

Scolstarin Latreille, 1807. Genera crustaceorum et insectorum ... 2:27.3 Type-genus: Scolytus Geoffroy, 1762, see China 1962).
The first noteworthy attempt to summarize the known information about the Scolytidae of North America was that of LeConte (1868), who treated 17 genera and 94 species. In a later summary he (LeConte 1876) included 26 genera and 123 species. Both reviews treated only the fauna of Canada and the United States. In his treatment of the fauna of Mexico and Central America, Blandford (1895-1906) recognized 4 tribes, 45 genera, and 270 species. Swaine (1918) treated the fauna of Canada and part of the United States, listing 4 subfamilies, 52 genera, and 226 species. In an uncritical summary of previous work, Chamberlin (1939) listed 5 subfamilies, 71 genera, and 571 species from Alaska, Canada, and the United States. Bright (1976) recognized 3 subfamilies, 45 genera, and 214 species in Alaska and Canada. The present study is the first attempt to treat the Scolytidae of all of North America, including Central America; 2 subfamilies, 20 tribes, 94 genera, and about 1430 species are listed. This represents an estimated 23 percent of the known world fauna.

Speeulation as to the apparent degree of eompleteness of our knowledge of the scolytid fauna of this area might be of interest in view of the experience that has resulted from the preparation of this work. It is supposed that 95-97 percent of the species in Alaska, Canada, and the United States are known. Those awaiting discovery will probably be sibling (eryptic) species that can be detected only through intensive biological studies or host specifie species that breed in rare or umstudied hosts. Perhaps no more than 80-85 percent of the Mexican fauna is known; most indiscovered species there should be found in noneoniferous hosts. It is doubtful that as
much as 70 percent of the Central American fauna is known; unfortunately, the rapid rate at which natural habitats are being destroyed there may cause the extinction of many species before they are discovered by science. Since 37 foreign species have already been introduced into the area, additional species should be expected from this source and may already be established (Wood 1977).

While I was engaged in a review of the various classifications of subfamilies and tribes for the Scolytidae by previous workers, it became apparent that they were based on only a minor segment of the family and could not adequately be used for the entire world fauna. In an effort to alleviate this deficiency, a new classification was proposed (Wood
1978) that was based on representatives of about 90 percent of known genera in the world fama and that utilized characters not previously employed in scolytid classification. In addition, that contribution contains the first attempt, since priority at the familygroup level became mandatory, to list subfamily and tribal names according to their priority. For these reasons the subfamily and tribal divisions may be somewhat different and the names selected less familiar than those presented by earlier works.

The various groups are presented in the following key in as nearly a phylogenetic sequence as present knowledge permits. Obviously, there is much opportunity for improvement.

## Key to Subfamilies, Tribes, and Genera ${ }^{2}$

1. Each basal margin of elytra procurved and armed (Fig. 16) by a series of marginal crenulations (or less commonly by a continuous elevated costa in some Bothrosternini and Diamerini), usually with a scutellar emargination between them; scutellum usually small and rounded or depressed, absent in some groups; pronotum weakly if at all declivous on anterior half, usually unarmed but crenulations sometimes present on anterolateral areas; head usually visible from above, somewhat wider; protibiae usually wider; seales or deeply divided setae a common feature; subfamily HYLESININAE

- Basal margins of elytra forming a straight transverse line across body, unarmed, rarely (some Scolytini, Ctenophorini, Cryphalini) with a weakly elevated continuous line (Fig. 17); scutellum usually large, flat (rarely absent or highly modified in some Xyleborini); pronotum weakly to strongly declivous on anterior half and usually armed by many asperate cremulations particularly on median half; head usually partly or entirely concealed from dorsal aspect, somewhat narrower: protibiae usually narrower; scales or deeply divided setae an uncommon feature; subfamily SCOLYTINAE
2(1). Scutellar area of metanotum and its postnotum separated by a suturelike intersegmental membrane (Figs. 18, 33 No. 43); posterior part of scutoscutellar suture strongly curved mesad to a point near costa or crest of scutellar groove then continuing cephalad parallel to this costa for about two-thirds length of metanotum (Fig. 18) (except much less in Phrixosomini and Hyorrhynchini); metapleural suture descending subvertically from pleural wing process to metepisternal groove formed to receive corresponding costal groove and flage of elytron then abruptly angled and continued caudad along this groove to a point near pleural coxal process (Figs. 19, 33 No. 46); scutellum visible; funicle 6-7-segmented or if 5 -segmented (Sueus, Oriental) then male frons not impressed and antennal club symmetrical
- Scutellar area of metanotum and its postnotum fused on at least median third, intersegmental suture obsolete (Figs. 21, 33 No. 42); scutoscutellar suture less strongly curved, approaching costa of scutellar groove more gradually and continuing cephalad parallel to it for less than half length of metanotum (it never reaches margin of this groove in some groups) (Fig. 20); metapleural suture sometimes as described above, but more commonly running a more direct route from pleural wing process to pleural coxal process, often remote from locked position of costal margin of elytra for most or all of its course; scutellum either not visible or if visible then funicle 5segmented and male frons impressed (except Bothrosternini with 6 -segmented funicle but with a distinctive protibia)

Fig. 16. Phloeotribus setulosus: Posterolateral aspect of male, note cremulations on basal margins of elvtra, visible metepisternum, and pseudolamellate antennal club.

Fig. 17. Scolytode's plameriae: Dorsolateral aspect of female.
Fig. 18. Hylastes nigrims: Dorsolateral aspect of meso- and metatergum with wings removed; note intersegmental and scutoscutellar sutures (arrows).

Fig. 19. Hylastes nigrinus: Lateral aspect of metapleuron (dorsal area at upper left), note pleural sutures and groove on metepisternum that locks costal margin of elytron in place (arrows).

Fig. 20. Hylastes nigrinus: Ventrolateral aspect of prothorax; note the costate precoxal ridge (arrow).
Fig. 21. Eupagiocerus dentipes: Dorsal aspect of metatergum; note incomplete intersegmental suture (is), the completely fused postnotum ( pn ), and the divergent scutocutellar suture (ss).

3(2). Eye entire to feebly emarginate; scutoscutellar suture parallel to costa of scutellar groove for two-thirds length of notum (Fig. 33 No. 43); precoxal ridge on prothorax present or absent; antennal funicle 5-7-segmented Eye completely divided by an emargination, halves widely separated; scutoscutellar suture remote from costa of scutellar groove (Fig. 33 No. 41); crenulations on basal margin of elytra low, often poorly formed; precoxal ridge on prothorax never present: antennal funicle usually 6 -segmented (5segmented in Oriental Sueus)
4(3). Prothoracic precoxal area rather large, its lateral margins strongly, sharply elevated from anterior margin to coxae (Fig. 20); crenulations on elytral bases usually poorly developed; antennal funicle 7 -segmented, club conical, segment 1 about as long as others combined; head somewhat prolonged, subrostrate, frons never sexually dimorphic (Fig. 14A); eye entire, rather short; Northern Hemisphere except introduced elsewhere; in Pinaceae (Tribe Hylastini)

- Prothoracic precoxal piece small, short, its lateral areas elevated or not; crenulations on elytral bases more conspicuously elevated, forming a definite row (except confused in Dactylopalpus, African); antennal funicle variable, 5-7-segmented, club) weakly to moderately flattened; head less distinctly rostrate, male frons usually impressed; eye oval to elongate, entire to feebly emarginate

5(4). Anterior coxae rather widely separated by an intercoxal piece, its width at least equal to half width of a coxa (as in Fig. 26); striae 9 and 10 both independently continued at least to level of abdominal sternum 4; elytral vestiture sparse, recumbent, yellow, hair- or bristlelike, never including scales; general surface of elytra and pronotum rather dull; body color reddish brown

- Anterior coxae contiguons or at most with intercoxal piece narrower than one-fourth width of a coxa (as in Fig. 20 or 28); striae 10 obsolete behind level of posterior coxae, only striae 9 continues caudad; elytral vestiture longer, more abundant, usually including at least some small scales
6(5). Third tarsal segments broad, bilobed; pronotum usually constricted anteriorly, usually about equal numbers of small and large punctures intermixed on disc.
- Third tarsal segments narrower, emarginate; pronotum not noticeably constricted anteriorly, punctures uniformly large or small, rarely intermixed with a few small ones
7(4). Pronotum asperate on anterolateral areas (except Hylastinus); prothorax with strongly elevated costate ridge from coxa to anterior margin; antennal funicle $6-7$-segmented; mesal surface of elytra at base of suture immediately behind scutellum with an interlocking series of nodules and cavities (as in Fig. 22A-B), this lock interrupts groove and flange of suture (not visible when elytra in locked position); worldwide (Tribe Hylesinini)
- Anterolateral areas of pronotum unarmed; precoxal costa on prothorax absent; funicle 5-7-segmented: mesal surface of elytra at suture with interlocking groove and flange contimued to base without a series of nodules or cavities immediately behind sentellum (Fig. 22C); worldwide (Tribe Tomicini)

8(7). Anterolateral areas of pronotum unarmed by asperities; precoxal prosternum longer, its lateral margins from coxa to anterior margin strongly, acutely elevated, coxae more widely separated, intercoxal piece at least equal to half width of a coxa; eye entire; antennal chb conical; breed in roots of clover .... Hylastinus

- Anterolateral areas of pronotum usually armed by a few asperities; prosternum very short, its lateral margins obtusely, if at all, elevated, coxae more narrowly separated, intercoxal piece equal to less than one-fourth width of a coxa; breed in bark and wood of trees
$9(8)$. Dorsal vestiture scalelike; eye rather short, entire; costal margin of elytra ascending toward apex; in Fraxinus
- Vestiture hairlike; eye moderately long and shallowly emarginate to
exceedingly elongate; costal margin of elytra descending toward apex ..... 10

IO(9). Antennal scape long, its apex attaining posterior margin of eye; eye comparatively short, shallowly emarginate; length usually less than 4.0 mm ; western USA and Canada; in Alnus

Alniphagus

Fig. 22 A-B. Pseudohylesinus n. nebulosus: Mesal aspect of sutural margin at base of elytra; note that the sutural grooves continue to the base without interruption.

Fig. 22C. Phlocosinus cristatus: Mesal aspect of sutural margin at base of elytra; note the interlocking cavities and nodules at the anterior end of the sutural grooves.

| - | Antennal scape short, not attaining posterior margin of eye; eye exceedingly elongate, often subcontiguous both dorsally and ventrally; usually larger than 8 mm ; tropical species $\qquad$ Phloeobo |
| :---: | :---: |
| 11(7). | Antennal funicle 7 -segmented, club conical, feebly flattened in a few species |
| - | Antennal funicle 5-segmented, club moderately to rather strongly flattened |
| 12(11). | Vestiture scalelike; antennal club with segment 1 longer, usually about onethird of its total length; epistomal margin (and premandibular lobe, when present) with a small, median sulcus, sulcus usually ornamented by a few setae; western North America; in coniferous hosts $\qquad$ Pseudohylesi |

- Vestiture more slender; antennal club with segment l shorter, about onefourth of its total length; epistomal margin continuous, without a median sulcus or setae; anterolateral area of pronotum with a few fine asperities; eastern North America; in Ulmus

Hylurgopinus
13(11). Vestiture scalelike; area immediately above epistomal margin without an

- Vestiture hairlike; epistomal process well-developed; larger species

## Dendroctonus

14(3). Protibia armed on outer apical margin by several socketed denticles of approximately equal size (as in Fig. 34); procoxae contiguous; frons convex, not sexually dimorphic; antennal scape elongate, suture 1 of club partly septate; pronotum never armed by asperities; America, Africa (Tribe Phrixosomini)

Phrixosoma
Protibia with outer apical angle produced into one conspicuous spine reaching level of tarsal insertion, outer margin without any socketed teeth (as in Figs. 27 or 29 ); procoxae rather widely separated; male frons broadly impressed, female frons convex; antennal scape either long or short. club aseptate; pronotum either with or without asperities in anterolateral areas; southeast Asia

Hyorrhynchini

Fig. 23 A-B. Eupagiocerus dentipes: Posterior face of protibia: A, note the bifid outer apical process and B, the socketed lateral tooth.

15(2). Lateral margins of pronotum usually subacutely elevated, costate; mesepimeron moderately to very large, its dorsal portion usually grooved for reception of elytral base; scutellar shield under base of elytra large, extending posteriorly beyond visible scutellum; scutoscutellar suture remote from costa of scutellar groove to its base; outer apical angle of protibia often with only one major, recurved spine; Africa, southeast Asia to Australia $\qquad$ Diamerini

- Lateral margins of pronotum usually rounded (subcostate in some neotropical Bothrosternini); mesepimeron not enlarged or grooved (feebly grooved in Aricerus, Australia); scutellar shield beneath elytra small if present, not extended caudad beyond visible scutellum; scutoscutellar suture near and parallel to costa of scutellar groove on at least anterior fourth of metanotum
16(15). Outer apical angle of protibia with a curved bifid process (Fig. 23), mesoand metatibiae with one or two (usually smaller) curved spines on outer apical angle extending beyond level of spine on inner apical angle; pronotum smooth or longitudinally strigose; funicle 6 -segmented; lateral prosternal area usually subacutely elevated from coxa to anterior margin; anterior coxae widely separated; crenulations on elytral bases rather small or (rarely) replaced by a continuously elevated costa; eye entire; America (Tribe Bothrosternini)
- Onter apical margin of protibia armed by several teeth of about equal size (except Aricerus in Phloeotribini, Australia), none of them extending beyond tarsal insertion; funicle 4-7-segmented; prosternal area with margins rounded, costa obsolete; eye varying from entire to emarginate to divided
17(16). Lateral margins of pronotum rounded ..... 18

Lateral margins of pronotim marked by a sharply elevated, costate to subcostate line (Fig. 24)
18(17). Sutures of antemal chab transverse, straight; rostrum distinctly wider than distance between eyes; pronotum either longitudinally strigose or punctured; pith borers of twigs and woody vines $\qquad$ Cnesinus
$\left.\begin{array}{ll} & \begin{array}{l}\text { Sutures of antennal club strongly procurved; rostrum width at tip equal to } \\ \text { distance between eyes; frons excavated, with a median tubercle just above }\end{array} \\ & \text { epistoma; body oval; seed borers ................................................................................................................................................................................................................... } 20\end{array}\right]$.

25(24). Eye entire; antennal club flattened, elongate, about equally divided by two strongly constricted, straight sutures; elytral ground vestiture rather abundant, subplumose Carphotoreus

- Eye deeply emarginate; antennal club subglobular, recurved sutures indicated only by rows of fine setae; elytral ground vestiture sparse, mostly obsolete, hairlike when present

Cladoctonus
26(23). Eye emarginate (completely divided in a few ludo-Australian species); antennal club marked by at least two oblique sutures, moderately asymmetrical; tarsal segment 3 broad, somewhat bilobed; pronotum never armed by asperities; in coniferous hosts (mostly Cupressineae) Phloéosinus

- Eye entire; antennal club large, strongly asymmetrical, sutures obsolete; tarsal segment 3 slender; pronotum commonly with asperities in anterolateral areas; never in coniferous hosts

Chramesus

27(21). Eye sinuate or entire; pronotum armed by a few scattered or clustered asperities; crenulations at bases of elytra restricted to area between suture and interstriae 5; funicle 3-5-segmented; scutoscutellar suture remote from costa of scutellar groove on anterior fourth of metanotum; almost worldwide (Tribe Hypoborini)

- Eye emarginate or entirely divided; pronotum never armed by asperities; crenulations at bases of elytra more widely distributed, extending laterad beyond interstriae 5 ; funicle 5 - or 6 -segmented; scutoscutellar suture passing near and parallel to costa of scutellar groove on anterior fourth of metanotum; Northern Hemisphere, Africa (Tribe Polygraphinı)

28(27). Antennal funicle 5 -segmented, sutures of club transverse, distinct; elytral vestiture without conspicuous recumbent hair; pronotum armed by two or three widely separated, paired clusters of teeth

Chaetophloeus

- Antennal funicle 4 -segmented, sutures of club indicated only by marginal notches; elytra with uniseriate rows of erect, broad interstrial scales and recumbent strial hair of equal length; pronotum armed by three or four pairs of median tubercles

Liparthrum
29(27). Eye divided; elytral punctures very small, confused, strial rows not evident; antennal club without sutures; antennal funicle 5 - or 6 -segmented

Polygraphus

- Eye emarginate; strial rows clearly indicated by rows of coarse punctures; antennal club with sutures clearly marked 30

30(29). Antennal funicle 6-seginented; elytral ground vestiture hairlike; on
Cupressinae .......................................................................................... Carphobius

- Antennal funicle 5-segmented; elytral ground vestiture scalelike; on Abietineae

Carphoborus
31(1). Lateral margin of pro- and metatibiae unarmed except for a single, apical, spinelike process that curves toward and extends beyond process of inner apical angle; lateral margin of pronotum subacutely elevated, costate (Fig. 25); pleural suture descending subvertically from pleural wing process to groove receiving groove and flange on costal margin of elytra, at this point suture turns abruptly and follows groove caudad to metapleural coxal process (Fig. 25); funicle 7 -segmented, sutures of antennal club strongly procurved or obsolete; Holarctic and Neotropical (Tribe Scolytini)

- Lateral margin of protibia armed by more than one denticle, none of which exceed or curve toward inner apical process; pleural suture less strongly angulate, groove receiving flange of costal margin of elytra displaced ventrad from course followed by pleural suture; lateral margin of pronotum subacutely raised or not, antenna variable

32(31). Scutellar area of interstriae 1 not depressed, scutellum even (flush) with elytral bases; basal margins of elytra with a fine raised line (broken into minute crenulations in some Cnemonyx), outline of anterior margins form a continuous, straight, transverse line with scutellum; ventral profile of abdomen ascending gradually33

- Scutellum depressed, subtriangular, apically (posteriorly) pointed; elytral bases depressed in scutellar area, appearing emarginate in median area; ventral profile of abdomen usually ascending abruptly at segment 2

33(32). Antennal club usually with two or three sutures clearly marked by setae; scutellum small, longer than wide, often convex; apical margin of meso- and metathoracic tibiae commonly bearing tubercles on anterior edge in addition to inner and outer processes; usually more coarsely sculptured, smaller species, less than 2.5 mm ; phloeophagous

Cnemonyx

- Antennal club with only suture 1 marked internally by a partial septum; scutellum flat, 1.5 or more times as wide as long; meso- and metathoracic tibiae acutely margined on apical anterior edge, without supplemental denticles; usually very finely sculptured; $2.2-8.5 \mathrm{~mm}$; xylophagous ambrosia beetles

Camptocerus
34(32). Humeral margin of elytra deeply, broadly excised, metepisternum conspicuously expanded into this notch; abdomen abruptly flexed upward at posterior margin of segment 2; phloeophagous; tropical

Scolytopsis

- Humeral margin of elytra normal (straight) and overlapping metepisternum; abdomen flexed upward from anterior margin of segment 2; phloeophagous .

Scolytus

35(31). Metepisternum visible throughout its length, slightly more than its dorsal half covered by elytra when in locked position, either with a conspicuous groove for reception of costal flange throughout its length or else groove represented at its anterior end by a denticulation or costate remnant near anterior end of metepisternum; antennal club varying from flat to obliquely truncate36

- Metepisternum largely covered by elytra, its groove for reception of costal
flange obsolete, a small, transverse callus (Cryphalini) (Fig. 31) or a small
transverse groove (Corthylini) (Figs. 32 or $33: 47$ ) at anterior end of mete
pisternum; antennal club strongly flattened; antennal club never obliquely
truncate ..... 70
36(35). Lateral margins of pronotum subacutely elevated, basal margin of elytra usually finely elevated (Fig. 16); procoxae rather widely separated (Fig. 26) except contiguous in Xyloctonini (Africa to SE Asia); protibia with promi- nent outer apical process recurved, usually extending beyond tarsal insertion (Fig. 27), posterior tibia tapered on apical third and armed by several small socketed denticles; funicle 6-7-segmented; tarsi often retractile into tibial grooves ..... 37

Lateral and basal margins of pronotum rounded; procoxae subcontiguous
(Fig. 28) (except most Micracini and a few Xyleborini); protibia with outer
apical angle inconspicuous, armed by several small socketed denticles;
funicle 2-6-segmented; tarsi not retractile (except Xyleborini) ..... 42
37(36). Eye divided or nearly so by a very deep emargination; antennal club flat, usually enlarged, with sutures strongly procurved; abdomen conspicuously ascending toward apex (not always clear in Ctonoxylon, Africa); tarsi always retractile into tibial grooves; Africa, SE Asia

- $\quad$ Eyes entire to shallowly sinuate on anterior margin; antennal club flat, usu- ally smaller, more slender, sutures variable if present; abdomen horizontal; tarsi retractile or not ..... 38

38(37). Antennal club unmarked by sutures; pronotum with sides strongly con
stricted on posterior half; scutellum absent (a small scutellum present in one
species); Africa to Asia, New Guinea (Fig. 30); mycetophagous

26

Fig. 24. Eupapiocerns dentipes: Lateral aspect; note the costate lateral margin of the pronotum.
Fis. 25. Comomyx panamonsis: Lateral appect. wing removed; note the costate lateral margin of the pronotum. plemal suture, and aroove for reception of elytra.

Fis. 2f. Acolytodes phameriar: Ventrolateral appect: note costate lateral margin of pronotum. visible metepistermm, and interntrat 10 arrow) that estend to posterior third of elytra.

Fis. 2-. Scolytodes schuari: Posterior face of protilia: mote lateral moseketed pine extending begond inner mexal apical ypine arrow.

> - Antemal club with one or more sutures indicated by grooves, setae, or septae; scutellmm large, flat; America; not mycetophagous (Tribe Ctenophorina)
> 39(38). Eyes elongate, approximate above and below, coarsely faceted, shallowly emarginate; entire surface of pronotmon smooth and punctured, not amed

40(39). Antennal chab subglobular, about as long as wide, sutures not clearly indicated; pronotum longer than wide, its lateral margins straight or feebly constricted; vestiture hairlike, usually sparse; small, slender species

Scolytodes
42(36). Procoxae moderately separated; protobiae with sides parallel, armed by denticles only on apical margin or posterior face; funicle 6 -segmented; female frons often concave, male frons rarely concave (two Pscudothysamoes): Africa, America (Tribe Micracini)43

- Procoxae contiguous (except Carphodicticini, some Xyleborini); protibia much wider apically, armed on lateral margin by several denticles; female frons rarely concave (a few Dryocoetini), male frons often concave; funicle $2-5$-segmented49

43(42). Elytra broadly rounded behind (subacuminate in Pseudothysanoes mucro
natus); lateral margins of antennal chb constricted at sutures 1 and
(usually) 2, except when sutures totally obsolete ..... 44

Elytral apices acuminate (partly lost in some Micracisella), usually mucro
nate; antennal club without sutural constrictions, sutures always indicated
on anterior face ..... 46
44(43). Pronotum longer than wide, summit less strongly developed; protibia rather broadly flattened, sides parallel, subtruncate apically

Thysanoes

- Pronotum as wide or wider than long, summit well developed; protibia slender, weakly or not at all flattened ..... 45

45(44). Elytral declivity in both sexes variously sculptured but never sulcate; antennal scape long or short, club with or without sutures; mostly phloeophagous, a few xylophagous

Pseudothysanoes

- Elytral declivity bisulcate, subvertical; antemal scape short, flattened, little if any longer than pedicel, chub small, widest through basal half, sutures 1 and 2 straight, indicated by rows of setae; phloeophagous Stenocleptus

46(43). Eye short, oval, not more than 1.5 times as long as wide, finely faceted; an
temnal club small, sutures straight to weakly procurved or bisinuate; protibia
slender ..... 47

- Eye elongate, 2.0 or more times as long as wide, coarsely faceted; antennal club rather large, sutures very strongly procurved; anterior tibiae rather strongly flattened45

47(46). Sutures 1 and 2 on antennal club straight, visible only at margins, obsolete in central area, club small; protilia entirely unarmed on posterior face, smooth; phloeophagous Phloeocleptus
Sutures 1 and 2 on antemal chub weakly procurved to bisimuate, clearly visible in central area of anterior face, club larger; protibia armed on posterior face by many tubercles or rugae; xylophagous

48(46). Eye shallowly emarginate, often approximate below; anterior tibiae less strongly flattened, at least one of five distal teeth on outer margin; scape usually less strongly expanded; antennal club rather broad, sutures more broadly procurved; monogamous, pith beetles

Micracisella

- Eye entire, always widely separated below; anterior tibia more strongly flattened, all five teeth on distal margin; scape usually very strongly expanded; antennal club more elongate, sutures usually much more strongly, narrowly arcuate; bigamous, xylophagus

Micracis
49(42). Male frons strongly excavated, epistoma armed by a pair of (usually) fused spinelike horns of enormous size; funicle 5 -segmented, club often small and feebly flattened; eye small, entire; pronotum with summit near basal margin, projecting back over scutellum in some species; western United States and Mexico (Tribe Cactopinini) Cactopinus

- $\quad$ Not fitting above combination of characters

50(49). Meso- and metathoracic tibiae more slender, more abruptly narrowed on apical fourth, lateral and apical margins armed by fewer, coarser teeth; eye sinuate to shallowly emarginate (divided in Tiarophorus, Dryocoetini, Africa); pronotum sometimes with a raised line on basal or lateral margin; pregular area not depressed; sexes of similar size and body form (except male dwarfed and deformed in Coccotrypes and Ozopemon); habits varied but never woodboring or mycetophagous

- If eye completely divided into two parts and antennal funicle 4 -segmented then male frons deeply excavated and male equal in size to female; if eye emarginate (or if divided and funicle 5 -segmented) then male dwarfed, deformed, and flightless and female meso- and metathoracic tibiae expanded to just beyond middle then arcuately tapered to apex, its apical two-thirds on outer margin armed by a row of numerous small, closely set teeth of equal size, these usually supplemented in same row by submarginal hair on posterior face; male pronotum highly modified; pregular area depressed (except Premnobius); woodboring, mycetophagous62

51(50). Pronotum rather strongly, laterally constricted on posterior half, anterior half not declivous and unarmed by asperities; anterior coxae moderately separated; antennal club strongly flattened, marked by two sutures, sutures on posterior face almost equal to those on anterior face; South America, India to Ceylon

Carpiodicticini

- Pronotum not constricted, sides straight to arcuate, anterior half declivous, usually armed; anterior coxae contiguous; antennal club obliquely truncate (Fig. 29) or with sutures on posterior face strongly displaced toward apex (rarely with sutures obsolete)52

52(51). Elytral declivity moderately sulcate to elaborately excavated, with lateral
margins usually armed by tubercles or spines; pronotum more strongly
declivous on anterior third, asperities usually larger; worldwide (Tribe Ipinı) ..... 53

- Elytral declivity slightly flattened to convex, unarmed by tubercles, spines, or unusual sculpture; pronotum usually evenly arched from base to anterior margin; asperities fine and abundant when present57

53(52). Elytral declivity rather narrowly bisulcate, lateral margins rather broadly elevated, rounded, and armed by not more than three pairs of denticles; lower margin of declivity rounded; usually smaller than 3 mm

| - | Elytral declivity broadly, rather deeply excavated, margins acutely elevated and armed by three or more pairs of denticles (except one to six in tropical Acanthotomicus); lower margin of declivity with an acutely elevated transverse ridge separating declivital excavation from apical margin; usually larger than 3 mm $\qquad$ 55 |
| :---: | :---: |
| 54(53). | Prosternal intercoxal piece short, obtuse; female frons deeply, rather narrowly excavated (except meridianus and mexicanus); male declivity with two or three pairs of enlarged denticles; antennal club compressed, two sutures visible on distal third of posterior face $\qquad$ Pityogenes |
| - | Prosternal intercoxal piece long and acutely tapered; female frons convex; male declivity more narrowly impressed $\qquad$ Pityokteines |
| $55(53)$. | Antennal club obliquely truncate, sutures recurved; third (lowest) major denticle not on lateral margin of elytral declivity, displaced mesad from margin; eye of normal size; in coniferous hosts $\qquad$ Orthotomicus |
| - | Antennal club flattened, sutures either procurved or strongly bisinuate; lateral margin of elytral declivity armed by one to six major denticles, third (if present) on or incorporated into crest of lateral margin; eye usually abnormally large or else very small $\qquad$ 56 |
| $56(55)$. | Sutures of antennal club (when present) moderately to very strongly procurved; eve large, very coarsely faceted, its width about equal to length of scape, its length more than twice length of scape; in angiosperm hosts from <br> Mexico to South America $\qquad$ Acanthotomicus |
| - | Sutures of antennal club moderately to strongly bisinuate (except procurved in concinnus, mexicanus); eve small, finely faceted, its width equal to much less than length of scape, its length equal to much less than twice length of scape; in coniferous hosts from Canada to Nicaragua $\qquad$ Ips |
| $57(52)$. | Antennal funicle 4-6-segmented, club either obliquely truncate or with sutures on posterior face strongly displaced toward apex; anterior half of pronotum more strongly declivous and rather coarsely asperate (unarmed in Tiarophorus, Africa); worldwide (Tribe Dryocoetini) $\qquad$ 58 |
| - | Antennal funicle 2-3-segmented, club with sutures on posterior face about equal to those on anterior face; pronotum feebly declivous on anterior half and unarmed (minutely granulate in some Aphanarthrum, Africa, etc.), reticulate in many species; size small; Northern Hemisphere, Africa (Tribe Crypturgini) $\qquad$ 61 |
| 58(57). | Pronotum distinctly longer than wide, widest at middle; antennal club compressed or with membranous apical portion extending beyond corneous portion, sutures procurved; scutellum very small $\qquad$ 59 |
| - | Prothorax about as wide as long, widest on posterior third, sides converging rather strongly on anterior half; antennal club obliquely subtruncate, sutures transverse or recurved; scutellum moderate to large $\qquad$ 60 |
| 59(58). | Antennal funicle 4 -segmented; club compressed, sutures strongly arcuate; pronotum granulate on anterior half, punctured behind; host Acer |

Lymantor
Antennal funicle 5 -segmented; club less strongly compressed, sutures narrowly to rather broadly procurved; pronotum usually granulate to base; host Cucurbitaceae

Dendrocranulus

| $60(58)$. | Antennal club with basal corneous portion reaching beyond middle; declivity steep, abrupt, confined to posterior fourth of elytra; northern North America; in coniferous hosts ....................................................................... Dryocoetes |
| :---: | :---: |

Corneous portion not reaching middle of antennal club in central area; de-
clivity gradual, extending over at least posterior third of elytra; frons con-
vergently aciculate; southern USA to South America; in nonconiferous hosts
.......................................................................................................................cotrypes

61(57). Antennal funicle 2-segmented, club with one suture near apex; northern and
eastern North America

Crypturgus

- Antennal funicle 3-segmented, club with three sutures; northwestern North America

Dolurgus
62(50). Eye always completely divided into two parts; antennal funicle 4-segmented, base of club feebly to moderately corneous, usually pubescent to base; male subequal in size to female, his frons flattened or excavated and anterior margin of his pronotum more broadly rounded; male joins female in parental gallery, reproduction always bisexual; Europe, Asia, North America (Tribe Xyloterini)
Eye emarginate except divided in some Pseudoxyleborus (SE Asia); funicle 5segmented (3- or 4 -segmented in a few Asiatic forms); males flightless, dwarfed, deformed, anterior slope of pronotum variously excavated; male head convex; male absent from parental gallery except as progeny; partly parthenogenetic, males haploid; worldwide (Tribe Xyleborinı)
63(62). Subcorneous basal area of antennal club broadly, feebly procurved; anterior tibiae flattened, devoid of tubercles on posterior face in both sexes; male frons somewhat flattened; male distinctly smaller than female; long axis of female proepimeral excavation transverse

- Subcorneous basal area of antennal club strongly, narrowly procurved; female protibiae inflated and tuberculate on posterior face, flattened and tuberculate in male; male frons deeply, extensively, concavely excavated, convex in female; male pronotum subquadrate, its anterior margin unarmed and straight to weakly recurved, in female serrate and procurved; long axis of female proepimeral excavation longitudinal, very narrow

Trypodendron
64(62). Pregular area not depressed below surrounding ventral area of head; labial palpi cylindrical, comparatively slender; antennal club thickened at base, margin of thickened area procurved, not corneous, pubescent almost to base; lateral margin of pronotum subacute from base almost to anterior margin; posterior face of protibia minutely tuberculate; anterior margin of pronotum unarmed

- Pregular area depressed inward below ventral contour of head; labial palpi broad, segment 1 greatly enlarged: antennal club usually obliquely truncate, basally corneous, sutures if present recurved (except Sampsonius); lateral margins of pronotum more broadly rounded; protibiae usually smooth on posterior face (except Dryococtoides); anterior margin of pronotum armed or not
65(64). Antemal club often more strongly flattened, with two transverse or procurved sutures not attaining margins laterally but continuing separately, suture 1 continuing to and clearly visible on posterior face, suture 2 continuing to apex of club or more rarely to posterior face near apex, basal area more weakly corneous, both sutures equally elevated; anterior margin of pronotum always serrate
- Antennal club clearly, obliquely truncate, basal area strongly comeous, its distal margin on anterior face recurved, usually acutely marked, continuing to apex of club, a second suture sometimes indicated but entirely confined to anterior face, usually obsolete before apex and never acutely elevated; anterior margin of pronotum serrate or not

66(65). Antennal club rather strongly flattened, both sutures moderately to rather
strongly procurved; pronotum very slender, at least 1.4 times as long as
wide, its anterior margin armed by two very coarse serrations; elytra very
elongate, declivity gradual and as long as disc, ordinarily with unusual sculp-
ture and ornamentation; eyes very large, very coarsely faceted; tropical ........

- Antennal club with sutures straight, feebly procurved to weakly recurved; pronotum stout, less than 1.1 times as long as wide, its anterior margin usually armed by four or more moderately coarse serrations; elytra variously sculptured, moderately elongate 67

67(66). Anterior tibia inflated and armed on posterior face by several conspicuous, confused granules or denticles in addition to socketed teeth on outer margin; eyes averaging larger and more coarsely faceted Dryocoetoides

- Anterior tibia flattened, its posterior face smooth, entirely devoid of granules; eyes averaging smaller and more finely faceted

Theoborus
68(65). Anterior coxae widely separated by an intercoxal piece; body very stout, 1.9-2.3 times as long as wide; anterior margin of pronotum serrate; elytral dise occupying less than half of elytral length, declivity convex, devoid of major tubercles or processes

Xylosandrus

- Anterior coxae contiguous; body stout to slender, elytra variously sculptured

69(68). Basal margins of elytra rounded, forming an almost straight, transverse line across body; scutellar notch entirely filled by scutellum; scutellum flat, attaining level of elytral surface

Xyleborus

- Basal margins of elytra abrupt, precipitous in median area; scutellum conical, not filling scutellar notch, adjacent vertical sides of scutellar notch pubescent; posterolateral margin of elytral declivity often dentate, never carinate

Xyleborinus
70(35). Costal margin of elytra slightly to moderately ascending from base of declivity to apex; basal end of metepisternum armed by a callus or partial groove of degenerating metepisternal spine (Fig. 31); sutures on posterior face of antennal club more strongly displaced toward apex; funicle 3-5-segmented; tibiae more strongly flattened, usually armed by more than four denticles; vestiture commonly includes scales; eye usually entire, less commonly emarginate; worldwide (Tribe Cryphalinı)

- Costal margin of elytra descending toward apex (except Brachyspartus, South America); basal end of metepisternum with a small, transverse groove (Fig. 32) (concealed when elytra in locked position), elytra in locked position more completely cover metepisternum; sutures on posterior face of antennal club only slightly displaced toward apex; funicle 1-5-segmented; tibiae more slender, rarely armed by more than four socketed denticles; vestiture rarely includes scales (in tropical forms only); eve emarginate; almost worldwide except Australia (Tribe Corthylinı)
$\begin{array}{ll}71(70) . & \begin{array}{l}\text { Lateral margins of pronotum without a fine, raised line (indistinct in Scoly- } \\ \text { todes); eye sometimes sinuate, emarginate only in Stegomerus; costal margins } \\ \text { ascending only slightly posteriorly ......................................................................... } 72\end{array}\end{array}$
- Lateral margins of pronotum acute, at least basally, and with a fine raised line on basal third; eve emarginate (except Trischidias); costal margins of elytra ascending distinctly posteriorly

Fig. 24. Ips wooli: Ventral aypect of prothomax: note contiguons coxae (right coxa removed) and the absence of a peecoal ridee llant liber between covae s an artilact

Fis. 32. Corthylus panamensis. Iateral apect of metathoras with elytra romoved; note loss of epistemal groove and spine and it replacement b a small. ohligue. anterior groove arrow and the very different position of the pleural suture (arrow)

Fig. 33. Diagrams of Scolytidae metanota: 41, Chramesus hickoriae dorsal aspect arrow points to remnant of intersegmental suture; 42, same, pleuron (arrow at metepistermal spine; 4.3. Hylastes nigrinus dorsal aspect, with lalbels indicating intersegmental suture (is), postnotum ( pn ), soutellar groove (sg), and soutoscutellar uture ss): 4. same. lateral aspect, with labels at metepimeron (mn), metepisternum (ms), pleural suture (pu), and metepisternal spine a marked by arrow): 45, Cnemonyx panamensis, dorsal aspect (arrow point to intersegmental suture): 46, ame, lateral aspect (arrow points to metepisternal spine); 47. Pityophthorus crotonis, lateral aspect (arrow points to metepisternal groove that has replaced the spine of other tribes). (After Wood 197s.

72(71). Antennal club slender, 1.7-2.2 times as long as wide, apically pointed. sutures aseptate, straight; antennal funicle 5 -segmented; basal half of pronotum without scalelike setae; on Alnus, Populus, Salix $\qquad$ Trypophloeus

- Antennal club wider, less than 1.6 times as long as wide, apically rounded, sutures almost straight or procurved, often septate; funicle 4 - or 5 -segmented; basal half of pronotum with some scalelike setae

Fig. 34. Apex of posterior face of prothoracic tibia of Polygraphus rufipennis showing socketed denticles at margin.

73(72). Antennal club with three moderately to strongly procurved, aseptate sutures
marked by rows of setae
Antennal club with suture 1 at least partly septate, sutures either straight or
eise not marked by rows of setae .......................................................................... 75

74(73). Antemal funicle 5-segmented; eye shallowly, broadly emarginate; tropical ... ..................................................................................................................... Stegomerus

- Antennal funicle 4-segmented; eye entire; eastern USA ........................ Ernoporicus

75(73). Sutures of antennal club straight, suture 1 septate; anterior margin of pronotum slightly produced; lateral areas of pronotum with no indication of a raised line; northern North America

- Suture 1 indicated only on lateral half of antennal club by a strongly angulate septum, other sutures and median half of 1 obsolete; anterior margin of pronotum broadly rounded; lateral margins of pronotum rounded and marked by a fine, raised line; tropical Scolytogenes
76(71). Antennal club with sutures recurved, suture 1 aseptate; tarsal segment 3 broad and emarginate; American species only in coniferous hosts $\qquad$ Cryphalus
- Antennal club with sutures straight or procurved; tarsal segment 3 cylindrical; rarely in coniferous hosts
77(76). Antennal funicle 5-segmented, club large, with three aseptate, procurved sutures; strial punctures obsolete; male and female equal in size and appearance; vestiture aboudant; monogamous and phloeophagous

## Hypocryphalus

- Antennal club smaller, suture 1 often septate, funicle often with reduced segmentation, male dwarfed, much smaller than female, with eyes abnormally small, flightless, rare; pith beetles, some phlocophagous
78(77). Eye entire; club rather large, aseptate, funicle normally 3 -segmented, rarely 4 -segmented; body very stout, less than 2.3 times as long as wide, smaller than 1.1 mm ; SE USA

79(78). | Antennal club with suture 1 partly septate; raised lateral line extending only |
| :--- |
| one-third pronotum length from base; elytra clothed with rows of rather |
| abundant strial and interstrial setae; mature color usially dark brown to |
| black.................................................................................................. Hypothenemus |

- Antennal club aseptate; raised lateral line extending two-thirds pronotum length from base; sulglabrous, a few subspatulate interstrial bristles on declivity; mature body color usually rather pale yellowish or reddish brown

Cryptocarenus
80(70). Antennal funicle usually 5 -segmented (3- or 4-segemented in Dendroterus, Dacnophthorus), club usually smaller, symmetrical; prosternal intercoxal piece acutely pointed (except Dacnophthorus); pubescence usually more abundant, usially in rows on elytra; elytral declivity convex to bisulcate. armature conservative; bark and twig beetles (Subtribe Pityophthorina)81

- Antennal funicle 1 - to 5 -segmented, club usually much larger, commonly asymmetrical prosternal intercoxal piece absent (except obtuse in Gnathotrichus, Gnathotrupes); pubescence usually greatly reduced to obsolete or minute and strongly confused; elytral declivity convex to truncate to deeply excavated (weakly bisulcate in some Gnathotrichus), commonly with spinose processes; ambrosia beetles (Subtribe Corthylina)92

81(80). Basal and lateral margins of pronotum rounded, devoid of a fine, raised line; elytra rather coarsely punctured, unarmed declivity steep, usually subvertical and somewhat flattened on lower half, almost never bisulcate; discal vestiture abundant82

Basal and lateral margins of pronotum marked by a finely raised line; elytral
declivity more gradual, convex to bisulcate, often ornamented by granules ..... 8.3

82(81). Antennal funicle 5 -segmented, club with aseptate sutures strongly procurved; interstrial setae scalelike; male frons strongly, transversely carinate at upper level of eyes, female epistoma deeply emarginate to accommodate a pair of mandibular spines

- Antennal funicle 3- or 4-segmented, club with sutures at least slightly recurved, aseptate; elytral vestiture hairlike; female epistoma not emarginate, mandible never with projecting spines

Dendroterus
83(81). Sutures of antennal club moderately to very strongly procurved, only suture 1 septate, or if all external sutures obsolete then mesal half of suture 1 marked by an internal septum Araptus

- Sutures 1 and 2 clearly, equally marked by rows of setae and grooves, straight to moderately procurved, if procurved then both sutures at least partly septate (sutures straight when both almost obsolete) 84
84(83). Sutures 1 and 2 of antennal club aseptate and clearly marked by grooves and rows of setae; pronotal asperities continuing in lateral areas to base; larger species; in cones of Pinus (except banksianae in twigs)

Conophthorus

- $\quad$ Sutures 1 and 2 both partly to completely septate or if aseptate then either antennal club largely glabrous or body size much smaller; pronotal asperities not extending to basal margin except in some tropical species not found in coniferous hosts; mostly smaller species; never in cones of conifers85

85(84). Pronotum without a transverse impression behind summit, transition from asperate to punctured areas gradual or asperities continuous to base; rare tropical species

| $86(85)$. | Elytral vestiture hairlike; elytral declivity broadly, subconcavely impressed; larger species $\qquad$ Conophthocranulu |
| :---: | :---: |

- $\quad$ Interstrial setae scalelike (spatulate), in rows; elytral declivity convex; male frons armed

Spermophthorus
87(85). Sutures of antennal club moderately procurved, segment l shorter than 2 or 3; greater frontal pubescence a male character; elytral punctures fine, usually confused, short pubescence abundant, often scalelike, striae usually obsolete; mostly confined to Quercus; bigamous

Pseudopityophthorus

- Sutures of antennal club straight to weakly procurved, segments 1 and 2 subequal in length; pubescence never scalelike, less abundant, striae clearly evident or if confused than punctures rather coarse; almost never in Quercus (exceptions are tropical)

88(87). Antennal club rather large, 2.5 or more times as long as funicle;
monogamous ..... 89

- Antennal club proportionately smaller, usually less than 1.5 times as long as funicle; polygamous (except a few Pityophthorus) ..... 90
$89(88)$. Body stouter, 2.5-2.8 times as long as wide; elytral declivity convex; female pronotum with a pair of large, densely pilose areas in anterolateral areas; antennal club with only two sutures; in Pinus

Pityoborus

- Body very slender, 3.7-3.8 times as long as wide; elytral declivity strongly impressed; female pronotum without pilose areas; antennal club with suture 3 indicated by a row of setae; in Clematus and other vines; tropical

Dacnophthorus
On (88). Female head normal, pregula and mandibles not disproportionately
enlarged; antennal funicle usually 5 -segmented ............................... Pityophthorus

- Either female pregula greatly enlarged and bearing a tuft of hair or else female oral region abnormally broad and with mandibles greatly enlarged 91
$\begin{array}{ll}91(90) . & \text { Female pregula greatly enlarged and bearing a tuft of long hair, male } \\ \text { pregula only slightly enlarged; Arizona and New Mexico; in Pinus ..... Pityotrichus }\end{array}$
92(80). Antemal funicle 5 -segmented, club always symmetrical, with two or three clearly marked sutures; anterior tibia widest near apex, its posterior face usually flat, unarmed (a few minute granules in Gnathotrupes); elytral declivity conservatively sculptured
$-\quad \begin{aligned} & \text { Antennal fumicle } 1-\text { to } 3 \text {-segmented, club commonly asymmetrical, sutures } \\ & \text { often reduced or absent; tibiae variously sculptured; declivity frequently } \\ & \text { armed ................................................................................................................................... }\end{aligned}$
93(92). Sutures of antemal club straight to moderately procurved, segment 1 not noticeably reduced in size; elytral declivity convex to narrowly sulcate, subapical margin near apex acutely elevated, sutural apex entire, rather narrowly rounded behind; Canada to Costa Rica

94(92). Antennal funicle 2- to 3-segmented, club with two sutures clearly marked; elytral apex divaricate (except Metacorthylus, Glochinocerus), commonly explanate, declivity often elaborately excavated and armed by spines; protibia always slender, with posterior face inflated and tuberculate; body usually slender

$$
95
$$

Antennal funicle 1 -segmented, club with one, two or no sutures; elytral apex entire, declivity convex to rather weakly excavated, never explanate; prothoracic precoxal piece transverse, straight, not extended between coxae; protibiae variable; body comparatively stout
95(94). Procoxae contiguous, anterior wall of combined coxal cavities and precoxal piece transversely straight; protibiae similar in male and female, with marginal row of tubercles, posterior face either unarmed or with a longitudinal row of up to about four tubercles; posterior face of female antennal club with long hair sparse to absent; antennal funicle usually 3 -segmented, less commonly 2 -segmented; frons commonly with a sharply defined granulate area
Prothoracic precoxal piece moderately large, posteriorly angulate, occupying anterior portion of area between coxae; male protibia armed by coarse marginal serrations and a row of equally coarse serrations on posterior face, female protibia with posterior face moderately inflated and armed by numerous, confused, small tubercles in addition to coarser marginal row; posterior face of female antennal club ornamented by more abundant, long hair; frons never ornamented by a sharply defined granulate area

$$
97
$$

96(95). Elytra broadly rounded behind, posterior margin of declivity feebly if at allexplanate, weakly if at all divaricate; lateral margins of declivity armed bythree pairs of spines; antennal club oval to subtriangular, little if any longerthan wide; anteroventral (sternal) margin of prothorax flanged, bent or fold-ed posteriorly away from head, usually bearing a tuft of hair; pronotum usil-ally stouter, anterior margin usually serrate; antemal funicle 3 -segmented ....

## Tricolus

Posterior margin of elytral declivity strongly to profoundly explanate, weakly to profoundly divaricate; declivital armature variable, antennal club oval to very elongate; anteroventral margin of prothorax fitting snuggly against head, sparsely pubescent; pronotum usually much more elongate, anterior margin variously sculptured, rarely serrate; antennal funicle usually 3 -segmented, occasionally 2 -segmented

Amphicranus
97(95). Elytral apex divaricate, often also explanate; antennal club oval to broadly triangular; lateral margins of pronotum usually with a fine, raised line; body moderately to very slender

Monarthrum
Elytral apex entire, never explanate; lateral margins of pronotum rounded;
antennal club more than twice as long as wide (except 1.6 times in male
Metacorthylus), its apex narrowly rounded; body comparatively stout ................ 98
98(97). Antennal funicle 3-segmented; female frons excavated and elaborately ornamented by long hair: antennal club not sexually dimorphic, elongate, slightly. asymmetrical; pronotum and elytral disc glabrous

Glochinocerus

Fig. 35. Posterior face of prothoracic tibiae: 25. Protohylastes annosus, with tarsus (Platypodidae): 26. Protoplatypus retulus, with tarsus (Platypodidae): 27, Mecopelmus zeteki, with first segment of tarsus (Platypodidae): 28 , Schedlarius mexicamus, with first segment of tarsus (Platypodidae); 29, Coptonotus cyclops, with first two tarsal segments (Platypodidae); 30, Tricolus peltatus (Corthylini); 31. Scolytodes sp. (Ctenophorimi); 32, Diamerus impar (Diamerini); 33. Camptocerus auricomus (Scolytini). (After Whood 1973:86.)

- Antennal funicle 2-segmented; frons convex and subglabrous in both sexes; antennal club asymmetrically very elongate in female, elongate-oval in male; pronotum and elytra minutely, closely pubescent $\qquad$ Metacorthylus
99(94). Lateral margins of pronotum rounded; elytral disc usually impunctate, declivity short, very steep, narrowly sulcate above, triangularly impressed below, costal margins near apex ascending slightly; antennal club subcircular, symmetrical, with two aseptate sutures marked by rows of setae; female frons convex, pubescence inconspicuous

Microcorthylus

- Lateral margins of pronotum marked by a fine raised line (except some Corthycyclon), elytral dise usually with clearly marked, confused punctures, declivity convex, truncate, or variously sculptured (but not as above); female frons usually moderately to strongly convex, often ornamented by hair; antennal club symmetrical to strongly asymmetrical, sutures present or not100

100(99). Antennal club aseptate, without sutures (some species with weak transverse grooves, without rows of setae), usually very elongate; lateral margins of pronotum cither with or without a fine, raised line; posterior face of protibia inflated and tuberculate; female frons broadly, evenly concave and ornamented by fine hair $\qquad$ Corthycyclon

- Antennal club with one or two sutures, its outline subcircular to strongly asymmetrical (if sutures absent then posterior face of protibia flat, smooth); female frons variable

101(100). Elytral declivity narrowly, weakly sulcate (except convex in one species), lateral margins armed by two or three pairs of pointed granules; antennal scape elongate, clubshaped; female frons variously impressed, with a pair of median carinae narrowly separated by a sulcus over part or all of median line; color pale yellow to yellowish broevn; antennal club symmetrical, broadly oval, with two finely marked sutures; protibia inflated, tuberculate ..

Corthylocurus
Elytral declivity convex, truncately concave, or variously impressed (but never narrowly sulcate); antennal scape subquadrate, stout; female frons never with pair of median carinae; antennal club slightly to profoundly asymmetrical, sutures (when present) rather strongly marked; posterior face of protibia smooth or tuberculate

Corthylus

## Subfamily HYLESININAE

Hylesinen Erichson, 1836, Archiv Naturgesch. 2:46 (Type-genus: Hylesinus Fabricins, 1801)

Anatomical features. - The subfamily Hylesininae is distinguished from the Scolytinae by the separately arcuate basal margins of the elytra, with this basal margin slightly elevated and armed by a series of crenulations or in primitive tropical forms by a contimuous costa, by the rather broad, deep sutural emargination, with the rounded or reduced scutellum slightly displaced posteriorly. In addition the head is usually visible from above, the pronotum is either unarmed or with most asperities confined to the anterolateral areas (a few exceptions), the body form tends to be stouter, and the anterior coxae more commonly are separated. The anterior tibiae are never as in Scolytus.

A few South American species in one section of Cnemonyx have basal crenulations on the elytra as well developed as in many Hylesininae. However, the character is not consistent nor present in all species of the group. The presence of this character in Cnemonyx indicates the primitiveness of the genus and suggests a possible point at which the two subfamilies might have diverged. The Hylesininae apparently arose after the Platypodidae had diverged from the main line of scolytid evolution and after the Scolytini had diversified, from a group perhaps not very unlike the more highly evolved Cnemonyx. The superficial resemblance of some genera, Hylastes and Hylurgops, to certain weevil genera can be attributed as much to evolutionary convergence to meet certain conditions in the environment as to genetics.

Biological features.- Almost all North and Central American genera of Hylesininae
are phloeophagus. The pith feeding Bothrosternini clearly were derived from phloeophagous types (Cnesinus annectens Wood), including the mycetophagous Bothrosternus. Dendrosinus, Phloeoborus, and two or three species of Chramesus are xylophagous. The primitive type of parental gallery in the Hy lesininae was a transverse, biramous system as in Cnemonyx; longitudinal, pith, and radiate systems apparently were derived later as specializations appeared. All American species are monogamous except for the polygynous Polygraphus and Carphoborus, and for the apparent partial parthenogensis in some Bothrosternini. At least two tropical species of Phloeosinus (papuanus Schedl and a similar sympatric species) are also polygynous.

Taxonomy.- A complete absence of agreement in published literature on the classification of the Hylesininae led to a search for new characters that might make possible a more nearly phylogenetic classification of tribes and genera (Wood 1978). The (1) presence or absence of an intersegmental suture between the scutellar area of the metanotum and its postnotum, (2) the course followed by the scutoscutellar suture on the metanotum, and (3) the structural arrangement of details in the locking mechanism at the base of the elytra were found to have significance in the characterization of tribes and in the grouping of genera. The result of these discoveries was a classification of this subfamily that is quite different from that seen in previous works (Wood 1978). The genera are now arranged in more meaningful groups that reflect true structural and, it is hoped, genetic relationships.

Hylastes LeConte, 1876. Proc. Amer. Philos. Soc. 15:387 (Type-gemus: Hylastes Erichson. 18.36)

Anatomical features.- The head is distinctly subrostrate, scrobes are present, the frons is not sexually dimorphic, the eye is comparatively small and entire, the antennal funicle is 7 -segmented, the antennal club is conical with distinct sutures, the basal crenulations on the elytra are poorly developed, the ridges extending from the anterior margin of the coxae to the anterior margin of the prothorax are well developed, the tibiae are broadly expanded, and the tarsal segments are broad and pubescent.

Bıology.- All American Hylastini occur north from Honduras in coniferous hosts. They breed at or below the ground level in roots or in logs resting on the ground. The biramose adult tunnels are usually almost entirely in the phloem and evidently are not oriented with the grain of the wood. Larval mines wander irregularly in the phloem.

Taxonomy.- Interstriae 10 extends to the declivity in Scierus and the front coxae are rather widely separated, suggesting that this genus is much more primitive than Hylastes or Hylurgops. The Hylastini are a rather highly specialized group of primitive Hylesininae.

## Genus SCIERUS LeConte

Sciercs leConte, 1876. Proc. American Phlos. Soc. 15:390 (Type-species: Scierl's anNectevis Le Conte, monobasic)
Diagnosis.- This genus is very closely allied to Hylurgops LeConte, with which some European writers placed it in synonymy; however, it is distinguished from that genus by the much more widely separated anterior coxae, by the continuation of elytral inter-
striae 10 to the level of abdominal sternmon 5, by the complete absence of scalelike vestiture, and by the uniformly large pronotal punctures.

Description.- Length 2.7-4.3 mm, 2.2 times as long as wide; secondary sexual differences obscure except for male stridulating device on abdominal tergum 7; head subrostrate, frons convex above, a pronounced transverse impression at level half way between antennal bases and upper level of eyes, subinflated between impression and level of antennal insertion, flattened below; epistomal process not evident, premandibular epistomal lobe well developed. Eye elongate oval; entire. Antennal scape elongate, almost equal in length to 7 -segmented funicle; club conical. with three distinct sutures. Pronotum narrower than elytra, narrowed and constricted anteriorly, unarmed, surface dull, with uniformly large punctures. Scutellum small. oval, convex. Crenulations on elytral bases small, distinct; striae weakly impressed. punctures moderately large, deep; interstriae irregular dull, reticulate, obscurely punctured. Declivity convex, steep; more strongly sculptured than on disc, interstriae tubercilate. Vestiture consisting of sparse, yellow hair or bristlelike setae; never with scales on pronotum or elytra.

Distribution.- New Mexico to British Columbia and eastward in the spruce forests to Quebec.

Biology.- Usually found in the lower bole or roots of fallen trees or logs where they construct simple galleries in the cambium region. The larvae feed primarily on the phloem tissues.

## Key to the Species of Scierus

1. Pronotal surface granulose, setae not longer than diameter of a puncture; elytral interstriae irregular, suberenulate to crenulate on middle half of disc, length of setae not equal to more than half width of an interstriae; declivital
tubercles larger and more abundant; Alaska, British Columbia, and New Mexico to Newfoundland; Picea, rarely in Pinus; 2.7-3.7 mm

- Pronotal surface reticulate, setae about twice as long as diameter of a puncture; elytral interstriae only slightly irregular, not at all, or minutely crenulate on middle half of disc, length of interstrial setae about equal to width of interstriae; declivital tubercles small, not always easily seen; Alaska to Colorado; Abies lasiocarpa, Picea; $3.8-4.3 \mathrm{~mm}$

2. pubescens Swaine

## 1. Scierus annectens LeConte Figs. 36-37

Scierus annectens LeConte, 1876, Proc. Amer. Philos. Soc. 15:390 (Lectotype, sex?; Anticosta Island in Quebec; Mus. Comp. Zool., present designation)
Diagnosis.- Distinguished, often with some difficulty, from pubescens Swaine by characters summarized in the above key.

Male. - Length 2.7-3.7 mm, 2.2 times as long as wide; color yellowish to reddish brown with yellowish pubescence.

Frons convex above, transversely impressed at level half way between upper level of eves and level of antennal insertion, subinflated between this impression and level of

Fig. 36. Scierus annectens. (After Bright 1976:205.)
antennal insertion, flattened toward epistoma; premandibular epistomal lobe rather large; surface granulose, punctures indistinct; vestiture rather abundant, coarse, very short and inconspicuous.

Pronotum 0.83 times as long as wide; widest just behind middle, sides strongly arcuate on basal two-thirds, narrowed anteriorly and distinctly constricted just before broadly rounded anterior margin; surface minutely granulose, punctures distinctly impressed on disc, rather large, close, of almost uniform size; vestiture short, coarse, usually not longer than distance equal to diameter of a puncture.

Elytra 1.5 times as long as wide, 2.3 times as long as pronotum; sides almost straight and diverging very slightly on basal two-thirds to declivital base, somewhat narrowly rounded behind, posterior profile interrupted by declivital tubercles; crenulations on elytral bases small, distinct, not in a continuous row; striae distinctly impressed, punctures rather large, deep, poorly formed; interstriae about one and one-half times as wide as striae, irregularly convex, surface minutely granulate, obscure punctures confused, with their anterior margins elevated, mostly finely crenulate at least toward base and near declivity. Declivity steep, convex; sculpture much as on disc except striae proportionately wider; interstriae 1 and 3 weakly elevated, 2 impressed and terminated below by a ridge extending from junction of 3 and 9 to 1 ; interstrial crenulations more nearly tuberculate, uniseriate, moderately large except on lower half of 2 . Vestiture consisting of short, stout, recumbent interstrial setae; each seta about equal in length to diameter of strial puncture.

Female.- Virtually identical to male.
Distribution.-Alaska and Arizona to Newfoundland and Maine.

Fig. 37. Scicrus annectens: A, entrance hole; B, turning niche; C, larval mine; D, egg gallery. After Stewart 1965:926.)

ALASKA: Kenai. CANADA: Alberta: Banff. Jaspar Park, Lesser Slave Lake. British Columbia: Creighton Valley (Lumby), Glacier, Lorna, Pine Pass. Newfoundland: Pasadena, Sandy Lake (Badger). Ontario Frater. Quebec: Cascapiedia. Caspé Peninsula (Burnt Jam Creek, St. John River), Laniel, Trinity Bay. USA: Arizona: Chiricahua Mountains, San Francisco Mountains. California: Big Bear Lake. Colorado: Boulder. Durango, Meeker, Montezuma N. F., New Castle. Idaho Coeur d'Alene. Maine: Brunswick, Camp Caribou. Montana: Glacier, Pray. New Hampshire; Crooks, W. Stuartstown. New Mexico: Sante Fe Ski Basin. Oregon: Ashland, Gold Lake (Willamette N. F.). Utah: Ashlev N. F.. Fish Lake N. F., La Sal Mountains, Logan Canyon, Wolf Creek Pass.

Hosts. - Picea engelmannii, P. spp., rarely in Pinus contorta.
Biology.-Stumps, the lower bole, and roots of rather large, prostrate trees, or the lower side of logs are usually selected for attack. The adult galleries are in the cambium region mostly in the phloem and are of a simple monoramous type. The larvae feed primarily upon phloem tissues.

Notes.- The above treatment was based upon 352 specimens. Variation in the series examined appeared to be as great between individuals as between series from different areas. The first specimen in LeConte's
syntypic series, cited above, has been regarded as the type and is here designated as the lectotype of annectens. The fourth and last specimen in his series (Vancouver) is of Aniphagus aspericollis.

## 2. Scierus pubescens Swaine

Scierus pubescens Swaine. 1924, Canadian Ent. 56:257 (Holotype, female; Jasper Park, Alberta: Canadian Nat., Coll. 724
Diagnosis. - In addition to characters mentioned in the above key, this species is distinguished by the larger punctures on the pronotum and the elytral striae, by the finer. longer vestiture, by the finer sculpture, and by the more nearly shining, reticulate surfaces.

Male.- Length 3.8-4.3 mm, 2.26 times as long as wide; color reddish brown, with pale yellow vestiture.

Frons as in annectens but surfaces less granulose, vestiture slightly longer; frontal area somewhat more slender, transverse impression evidently deeper.

Pronotum 0.96 times as long as wide; as in annectens except sides much less strongly
arcuate, surface reticulate, not at all granulate, punctures larger, more sharply impressed, and vestiture finer, distinctly longer.

Elytra 1.7 times as long as wide; as in annectens except posterior profile more finely serrate, interstriae proportionately narrower, about as wide as striae, anterior margins of interstrial punctures much more finely crenulate, general surface coarsely reticulate, declivital interstriae less strongly convex, 2 much less strongly impressed, with all tubercles much smaller, and vestiture longer, each seta up to twice as long as width of a strial puncture.

Female.- Sexual differences not readily apparent except those involving abdominal terga.

Distribution.- Alaska to Colorado.
ALASKA: Kenai Peninsula, S-VI-74, trap, M. M. Furniss. CANADA: Alberta: Jasper Park, VIII-15, no. 22.32a, Picea, J. M. Swaine. British Columbia: Haines Road, 10-VIII-52; London Hill Mine. Bear Lake, 7000 ft , on snow; Loma, 22-VI-25, no. 16:3 lot 3807. Abies lasiocarpa. USA: Colorado: Argentine Road. 1938, Wichham; New Castle, VII-VIII, Hopk. US 31408 B , Picea engelmamnii, C. L. Massey: Idaho: Mc.Call, 23-VI to I2-VIII-72 Hopk. 58402 . D. R. Oakes.

Hosts.-Abies lasiocarpa, Picea engelmannii.

Biology.- Presumably similar to anneetens.

Notes.- The above treatment was based on the holotype and on 81 other specimens.

## Genus HYLURGOPS LeConte

Hylurgops LeConte, 1876, Proc. American Philos. Soc. 15:389 (Type-species: Hylastes pinifex Fitch, sul)serpuent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:123)
Diagnosis.- Within the tribe Hylastini this genus is very closely related to Hylastes, from which some species are distinguished with difficulty. In addition to characters mentioned in the above key, Hylurgops species normally have rows of fine, long, hairlike, interstrial setae on the declivity
(sometimes abraded); hairlike setae in Hy lastes, if present, are not longer than the ground vestiture.

Description.-Length 3.1-5.7 mm, 2.4-2.8 times as long as wide; secondary sexual characters clearly evident only on abdominal terga.

Frons with a transverse impression midway between level of antennal insertion and upper level of eyes, convex above, flattened to weakly convex below this point; lower area usually with a median carina. Eye subovate, entire. Antennal funicle 7 -segmented; club conical, basal segment much longer than others, at least two sutures indicated. Pronotum usually strongly constricted just behind anterior margin, surface unarmed, punctured. Scutellum small, oval. Crenulations on elytral bases poorly developed, bases usually not elevated; striae impressed or not, punctures distinct; interstriae variously sculptured. Declivity convex, steep. Vestiture including both hairlike and scalelike setae.

Distribution.- The Holarctic realm; seven species including two with subspecies occur throughout the coniferous forests of North and Central America south to Guatemala (and probably Honduras) wherever representatives of the Pinaceae are native. Thirteen additional species occur in the Palaearctic realm.

Biology.-All species construct hylesinine simple or biramous egg tunnels in phloem tissues and may engrave the wood slightly. Eggs are placed in niches and are packed in frass. The larvae mine phloem tissues in an aimless pattern; the larval tumnel usually is visible on the inner surface of peeled bark. The stump and roots are selected for attack by some species, others attack the bole or even limbs of fallen trees or they may invade logs. Some species breed primarily in injured or weakened green bark, others prefer logs with souring bark.

## Key to the Species of Hylurgops

1. Declivital interstriae equally convex, their tubercles small; pronotal vestiture
hairlike; crenulations on basal margins of elytra rather poorly developed ................ 2

- Alternate declivital interstriae strongly elevated and armed by rather large tubercles; pronotal ground vestiture consisting of abundant, small scales, some hairlike setae usnally intermixed; crenulations on elytral bases rather well developed

2(1). Posterior half of lateral margins on pronotum acutely elevated; lateral margins of pronotum straight on more than basal half, very feebly convergent; pronotal vestiture erect, rather abundant, long, many setae at least equal in length to those on declivity; longest declivital setae abundant, confused, not in rows; Arizona, New Mexico to Guatemala; 4.6-5.7 mm

1. incomptus (Blandford)

- Lateral margins of pronotum transversely rounded, moderately to strongly arcuate in outline from base to constriction on anterior fourth; pronotal vestiture recumbent, very short or absent; longest hairlike setae on elytral declivity in sparse, uniseriate rows
3(2). Body more slender, at least 2.5 times as long as wide; pronotum longer than wide; normal body color black; basal angles of pronotum rather abruptly rounded; transverse constriction on pronotum obscure4
- Body stouter, less than 2.3 times as long as wide; pronotum wider than long; normal body color dark reddish brown; basal angles of pronotum rather broadly rounded; pronotum with a distinct transverse constriction on anterior fourth
4(3). Small and large pronotal punctures only slightly different in size, most interspaces less than half as wide as diameter of a puncture; body stouter, 2.6 times as long as wide; Arizona and New Mexico to Honduras; 3.8-5.3 mm

2. planirostris (Chapuis)

- Largest punctures on pronotal disc about twice as large as smallest, most interspaces between punctures at least equal in width to smallest punctures; body more slender, 2.7 times as long as wide
5(4). Hairlike setae on pronotum and elytra very fine and exceedingly long, at least twice as long as distance between interstrial rows of long hair on elytra; high altitudes of Puebla and Mexico; 3.8-4.6 mm

4. longipennis (Blandford)

- Hairlike setae on pronotum and elytra shorter, length not exceeding distance between rows of interstrial hair6

6(5). Elytral surface smooth, shining; submarginal crenulations at base of elytra acute, marginal crenulations rather well developed; median frontal carina acutely elevated, extending a short distance above transverse impression near epistoma; pronotal punctures usually much coarser, deeper; British Columbia and Alberta to California and New Mexico; 3.3-4.6 mm 3. porosus (LeConte)

- Elytral surface minutely reticulate; elytral bases without acute crenulations, marginal crenulations rather poorly developed; frontal carina indistinct, visible only in transverse impression immediately above epistoma; pronotal punctures smaller, closer, usually not as deep; Northwest Territories to California and New Mexico; 3.7-5.0 mm 5. reticulatus Wood

7(3). Scalelike elytral vestiture confined to declivity; elytral dise with only a few crenulations in uniseriate rows, these usually narrow and more nearly tuberculate, most interstrial punctures on middle half almost normal (not crenulate); setae on lateral and basal margins of pronotum very fine; pronotum reticulate; California to Coastal British Columbia and Alaska; 3.6-4.8 mm
6. rugipennis rugipennis (Mannerheim)

- $\quad$ Scalelike vestiture extending anteriorly to middle of elytral disc; elytral dise with most interstrial punctures crenulate or subcrenulate, confused; setae on lateral and basal margins of pronotum coarse; pronotum smooth, shining (intermediate in zone of intergradation); Utah and Colorado to inland British Columbia and east through the coniferous forest to Nova Scotia and Alabama; 3.7-5.2
mm

7. rugipennis pinifex (Fitch)

8(1). Odd-numbered declivital interstriae rather strongly, more uniformly elevated and armed by moderately large tubercles; strial punctures smaller, interstrial bristles finger; N Arizona and N New Mexico to Alaska; 3.1-4.2 mm
8. subcostulatus subcostulatus (Mannerheim)

- Odd-numbered declivital interstriae very strongly elevated, conspicuously constricted laterally and in height between much coarser tubercles; strial punctures distinctly larger, interstrial bristles coarser; S Arizona and S New Mexico to Honduras; 3.3-4.4 mm

9. subcostulatus alternans (Chapuis)

## 1. Hylurgops incomptus (Blandford)

Hylastes incomptus Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6): I45 (Syntypes; Andrés Chatchicomula. now Ciudad Serdán, Puebla, Mexico; British Mus. Nat. Hist)
Hylurgops grandicollis Swame, 1917, Dom. Canada Dept. Agric. Ent. Br. Bull. I $4: 17$ (Lectotype, sex?; Clouderoft, New Mexico; Canadian Nat. Coll, designated by Bright, 1967. Canadian Ent. 99:675); Wood, 1957, Canadian Ent. 89:397. Synonymy
Diagnosis.- In addition to characters mentioned in the above key this species is distinguished by the deeply impressed centers of the pronotal punctures.

Female.- Length 4.6-5.9 mm, 2.6 times as long as wide; color black.

Frons with a moderately strong, transverse impression near middle about midway between upper level of eyes and level of antennal insertion, rather strongly convex above and weakly convex below except weakly impressed laterally just above epistomal margin; epistomal lobe broad, not very strongly produced; surface smooth and shining, with close, deep, rather coarse punctures; vestiture consisting of fine, long and short, rather sparse, hairlike setae.

Pronotum 1.1 times as long as wide; widest at base, sides very weakly arcuate and feebly converging on basal two-thirds, rather broadly rounded in front; lateral margins sharply, subacutely elevated on at least basal half; surface smooth and shining, with abundant, close, deep, medium and small punctures except on median line; an elevated median line visible on about three-fourths of pronotum length; vestiture consisting of rather abundant, erect, hairlike setae of variable length, many of them about as long as those on elytral declivity.

Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; sides straight and parallel on basal two-thirds to declivital base, then
rather broadly rounded behind; striae not at all impressed, punctures small, rather deep, obscure; interstriae at least twice as wide as striae, shining, interrupted by numerous deeply impressed, irregular, transverse lines, tubercles or crenulate elevations entirely absent. Declivity steep, convex; striae weakly impressed, punctures more nearly evident; interstriae 1 and 3 weakly, 9 moderately elevated, each bearing a row of fine granules; interstriae with moderately abundant, fine punctures. Vestiture consisting of short, rather sparse scales, and fine, long, rather abundant confused, hairlike setae on declivity and sides.

Male.- Evidently identical to female except on abdominal terga.

Distribution.- Arizona and New Mexico to Guatemala.

USA: Arizona: Chiricahua Mts., Flagstaff. Huachuca Mts., Oak Creek Canyon, Paradise, Santa Catalina Mts., Williams. New Mexico: Beutah, Capitan Mts., Cloudcroft. Coolidge, Las Vegas, Lincoln N. F., Peloncillo N. F., Santa Fe Camyon. White Mts. MEXICO: Chiapas: Mesa del Huracan, 24-VII-64, Pinus engelmannii, J. B. Thomas: San Cristóbal, 8-VII-69. Distrito Federal: 24 kin S El Guarda, 14-XI-46. Durango: 60 km , SW' El Salto, 23-Vll-5.3 Pinus. S. L. Wood. Hidalgo: 7 km E Zacatlán, 12-VI-67, 2900 m , No. 20, Pinus, S. L. Wood. Mexico: 70 km W Toluca, 15-VII-53, Pinus, S. L. Wood; Tlalmonalco, $P$. leiophylla, P. J. Perry. Puebla: 8 km SW Teziutlán, I8-VIII-58, Pinus, II. F. Howden. Tlaxcala: 20 km N Tlaxco, 9-V'il-67, Pinus, No. 181, S. L. Wood. Veracruz: 5 km E Perote, 15-VI-53, 2400 m , Pinus, S. L. Wood; Las Vigas, 18-Xll-48, H. B. Leech. GUATEMALA: Cerro Calel, Quezaltenango, 26-V-64, 3100 m , No. 620, Pinus pseudostrohus, S. L. Wood; San Cristobal, Huchuetenango, 28-V-64, 2300 m, Pinus psctudostrolus, S. L. Wood; Tecpam, 11-X-32, 600 m, Pinus.

Hosts. - Probably any species of Pinus within the distribution.

Biology.- This species breeds in stumps of dead or dying pines near or below ground level. Egg galleries are constructed primarily in the phloem tissues and lightly score or at least stain the surface of the wood. The irregular larval mines wander through the
phloem tissues and are usually visible on the inner surface of the bark through at least part of their length.

Notes.- The types of both incomptus and grandicollis were examined. The above treatment was based on my female homotype of incomptus from Cerro Calel and on I51 additional specimens.

## 2. Hylurgops planirostris (Chapuis) Fig. 41

Hylastes planirostris Chapuis, 1869, Synopsis des Scolytides, p. 21 (Lectotype. female; Suapan, Mexico; Mus. d'Hist. Nat., Brussels, subsequent designation by Wood, 1971, Great Basin Nat. 31:146)
Hylurgops knausi Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):17 (Lectotype, sex?; Cloudcroft, New Mexico; Canadian Nat. Coll., subsequent designation by Bright, 1967. Canadian Ent. 99:675); Wood, 1971. Great Basin Nat. 31:146. Synonymy
Diagnosis.- This species is closely related to porosus, but it may be distinguished by characters summarized in the above key.

Male.- Length 3.8-5.3 mm, 2.6 times as long as wide; color black.

Frons as in incomptus, but perhaps more coarsely punctured; median carina variable. Vestiture short.

Pronotum 0.9 times as long as wide (rarely 1.0); widest near middle, sides rather strongly arcuate from base to feeble constriction just before rather broadly rounded anterior margin; surface shining, densely punctured by rather deep punctures of almost uniform size, interspaces almost never as wide as diameter of a small puncture; glabrous except for a few setae on lateral margins.

Elytra 1.7 times as long as wide; as in porosus except striae tending to be less deeply impressed, punctures narrower, and interstriae perhaps less irregular and wider.

Female.- Differences not apparent except on abdominal terga.

Distribution.-Arizona and New Mexico to Honduras.

USA: Arizona: Alpine, Chiricahua Mts., Flagstaff, Globe, Graham Mts., Hanagan Camp (Greenlee Co.), Paradise, Patagonia. Pinaleno Mts., Santa Catalina Mts., White Mts. New Mexico: Alto, Buelah, Capitan, Cloudcroft, Las Vegas, Lincoln N. F., Magdalena (Socorro Co.), Pecos N. F., Sacramento Mts.. Silver City: MEXICO: Chiapas: El Bosque; 8 km S San Carlos, 6-III-6.3. R. C. Bechtel; 8 km E San Cristóbal, 8-VIl-69, Pinus ayacthiute, D. E. Bright. Chihuahua: Creel, 18-VII-60), and La Laja, 16-Vll-60, S. L. Wood. Distrito Federal: Mexico.

Durango: 16 km W El Salto, VII-64, J. B. Thomas. Hidalgo: 6 km E Zacatlán, 12-VI-67, S. L. Wood. Mexico: 70 km W Toluca, 15-VII-53. S. L. W'ood. Michoacán: 55 km E Morelia, 14-V1-65, Pinus, S. L. Wood. Tlaxcala: 17 km N Tlaxco, 9-V1l-67, Pinus, S. L. Wood. Veracruz: 26 km NW Jalapa, 29-V1-53, Pinus S. L. Wood; 11 km SE Las Vigas, 18-X11-48, H. B. Leech. CUATEMALA; Cerro Calel, 26-V-64, P. pseudostrobus, S. L. Wood; Tecpan, 24-IV-56, Pinus, R. L. Furniss; Totonicipán.

Hosts.- Evidently all species of Pinus within its range.

Biology.- This species tends to infest logs or the bole of fallen trees and, when abundant, may completely replace Ips in a given $\log$. The tunnels appear to be similar to those of incomptus.

Notes.- The above treatment is based on the lectotypes of planirostris and knausi and on 481 other specimens.

One specimen in a long series of this species, from Cloudcroft, New Mexico, and a unique specimen from the Chiricahua Mountains, Arizona, exhibit characters almost exactly intermediate between this species and porosus. Several specimens of both species from central Arizona and New Mexico suggest slight intergradation of characters between these two species. While the two intermediate specimens suggest hybridization or intergradation of species, the material presently at hand does not warrant reducing them to subspecies of one another.

## 3. Hylurgops porosus (LeConte) <br> Figs. 38.41

Hylastes porosus LeConte, 1868, Trans. American Ent. Soc. 2:175 (Lectotype, female?; California; Mus. Comp. Zool., designated by Wood. 1971. Great Basin Nat. 31: 147)
Hylurgops lecontei Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):16 (Holotype, sex?; Colorado; Canadian Nat. Coll.. 9242); Wood, 1971, Great Basin Nat. 31:147. Synonymy
Diagnosis.- This variable species is closely allied to planirostrus (Chapuis) and occasional specimens from the zone of overlapping distributions can be distinguished only by the relative size and density of pronotal punctures.

Female.- Length $3.6-5.3 \mathrm{~mm}, 2.7$ times as long as wide; color black.

Frons as in incomptus but perhaps more coarsely punctured; a median carina on
lower third sometimes more definite. Vestiture short.

Pronotum 1.1 times as long as wide (rarely to 1.0 ); sides usually widest one-third from base, moderately arcuate to a feeble constriction just before broadly rounded anterior margin, some specimens with sides on basal half almost straight and parallel; surface shining, with large and small punctures intermixed in variable proportions (most commonly in about equal numbers), largest
punctures about twice as large as smallest, some of interspaces on dise at least equal in width to diameter of a small puncture; median line usually visible on middle third; glabrous except at margins, setae short.

Elytra 1.8 times as long as wide, 1.9 times as long as pronotum; profile as in incomptus; striae usually slightly impressed toward declivity, punctures large, deep; interstriae slightly narrower than striae, punctures small, abundant, confused, surface usually

Fig. 3s. Hylurgops porosus: Outline from dorsal aspect, with seulpture of pronotum indicated.
Fig. 39. Iylurgops rugipennis pinifex: Outline from dorsal aspect, with sculpture of pronotum indicated.
Fig. 40. Hylurgops subcostulatus subpecies: A, s. subcostulatus, ontline from dorsal aspect; B, same, declivity: C. s. alternans, declivits.
shining, slightly irregular especially toward declivity. Declivity steep convex; striae and interstriae somewhat narrower; interstriae 1 (usually) and 9 weakly elevated; all interstriae with a row of uniseriate, widely spaced, fine granules. Vestiture consisting of small, moderately abundant scales on declivity and usually on posterior area of dise, and uniseriate rows of long, fine, erect, interstrial hair on declivity, usually abraded on disc, each seta about as long as distance between rows or less, spaced within a row by about once or twice this distance.

Male.- Evidently identical to female except on abdominal terga.

Distribution.- British Columbia and Saskatchewan to Arizona and New Mexico.

CANADA: Alberta: Banff, Cypress Hills, Laggen, Lake Louise. British Columbia: Asheroft, Aspen Grove, Atlin, Chilcotin, Cranberry Brook, Kingsvale, Lac Le Jeune, Lorna. Midday Valley, Sidney, Summerland, Trepan Creek, Trinity Vallev, Vancouver, Vermillion Summit, Vernon, Yoho Park. Saskatchewan: Cypress Hills. USA: Arizona: Flagstaff, Kaibab N. F., Prescott, California: Berkeley, Burney, Chester, Inverness, Lassen N. F., Northfork, Norval Flats. Oakland, Orinda, Pinecrest. Placerville, Plantation (Sonoma Co.), San Francisco, Sequoia N. P., Silver Lake, Summit Lake (Shasta Co.). Truckee, Tulare Co., Yosemite. Colorado: Byers R. S., Colorado N. F., Estes Park, Evergreen, Ft. Collins, Ft.

Fig. 41. Hylurgops spp., distribution map; porosus, solid circles; planirostris, open circles.

Garland, Glenhaven, Leadville, Pingree Park, San Juan N. F., Tercio, Uncompahgre N. F., Whitman. Idaho: Centerville, Ellis, McCall, Moscow, Salmon, Sandpoint, Winchester. Montana: Cabinet N. F., Columbia Falts. Flathead Lake, Helena, Niger Hill (Powell Co.), Rocks Boy Indian Reservation (Hill Co.), Seeky Lake. Nevada: Minden in Douglas Co. New Mexico: Hermit Peak near Sante Fe. Oregon: Beatty, Bly, Corvallis, Crater Lake, Gold Lake (Willamette N. F.), Grant Co., Klamath Falls, McMinnville, Medford. Pineville, Rankin, Santiam Pass. South Dakota: Black llills, Custer, Pine Ridge. Utah: Beaver, Elk Park (Ashley N. F.), Kamas, Logan Canyon, Long Hollow (Dixie N. F.), Panguitch, Soapstone (Uinta N. F.), Wolf Creek Pass. Washington: Buckeve, Cheney; Chewelah, Glenswood, Kooskookie, Thorton. Wyoming: Afton. Mountain View, Saratoga, Yellowstone N. P.

Hosts.- Pinus attenuata, $P$. contorta, $P$. flexilis, P. jeffreyi, P. ponderosa, P. radiata, less common in Picea.

Biology. - Essentially as in incomptus.
Notes. - This abundant and variable species is probably misidentified more commonly than any other North American scolytid. Within a series from any given locality the pronotal punctures and the impression of the elytral striae may vary considerably, but, contrary to Swaine's (1918:82) note, I fail to associate this variation with geography.

The above treatment was based on the lectotype of porosus, on the holotype of lecontei, and on more than 2000 other specimens. See the note above under planirostris concerning possible intergradation between these species.

## 4. Hylurgops longipennis (Blandford)

Hylastes longipennis Blandford, 1896. Biol. Centr Amer.. Coleopt. 4(6):143 Lectotype, female; Rancho de Popocatepetl. Mexico; British Mus. Nat. Hist., present designation)
Diagnosis.- This species is distinguished from porosus (LeConte) by the slightly smaller average size, by the more slender body form, by the more finely punctured frons, by the much steeper elytral declivity, and by the different declivital vestiture as described below.

Female.- Length 3.8-4.6 mm, 2.8 times as long as wide; color black.

Frons as in porosus except punctures averaging slightly smaller, median carina usually indicated but less well developed.

Pronotum as in porosus, punctures averaging slightly smaller.

Elytra 2.1 times as long as wide, 2.3 times as long as pronotum; similar to porosus except strial punctures slightly smaller, deeper, interstrial punctures slightly smaller, not at all subcrenulate, declivity much steeper, particularly on lower half, scales confined to declivity, much less abundant (concealing less than one-third of surface area, interstrial setae very fine, in rows, each seta one to three times as long as distance between rows, spaced within a row by about half distance between rows.

Male-Similar to female except median frontal carina less distinct.

Distribution.- Mexico.
MEXICO: Mexico: Rancho de Popocatepetl, h(eight)t 3500 metires), Septr.. E. Trucpui; Popocatepetl. VH-VHI-78, pheromone trap, Hopk. 61847, M. M. Furniss; 11 miles ( 17 km ) E Amecame (a, 31-V-74, 3200, C. W. and L. O'Brien; Parque Zoquiapan, 15-X11-79. T. H. Atkinson.

Notes.- Blandford named longipennis from a syntypic series of five specimens labeled "Truqui, Mexico" from the Frey collection. One of the specimens bears the number 23337 and, according to Dr. R. T. Thompson, is listed in the Frey collection register with the note "Rancho de Popocatepetl, h(eight)t 3800 met(res) Septr."; it was collected by Eugen Truqui some time prior to 1860. Included in the entry is "Tomolips asperatus Woll(aston) Type." Since Tomolips bicalcaratus Wollaston (=asperatus Wollaston) (family Curculionidae) is a relatively common species in the stumps and roots of Pinus leiophylla, and perhaps other pines in the Estado de Mexico, it is assumed that longipennis occurs in this habitat.

Since a type has not been selected from Blandford's syntypic series, I here designate the second specimen in the series, a female, as the lectotype for Hylastes longipennis Blandford. In addition to the five syntypes, 10 specimens were examined.

## 5. Hylurgops reticulatus Wood

Hylurgops reficulatus Wood, 1971, Great Basin Nat. 31:71 (Hoktype, made: Summit Lake, Shasta Co. California; Wood Coll.)
Diagnosis. - This species is distinguished from porosus (LeConte) by the larger average size, by the minutely reticulate elytra, and by other characters included in the above key.

Male.- Length $3.7-5.0 \mathrm{~mm}, 2.8$ times as long as wide; color black, with whitish vestiture.

Frons as in porosus except lower half less deeply, less closely, less finely punctured; median carina almost obsolete, visible only in impression immediately above epistoma.

Pronotum as in porosus except usually widest near middle, converging anteriorly more abruptly; surface often partly or entirely reticulate, punctures about as on some porosus but finer than on most; largest punctures about twice as large as smallest, spaced by distances equal to or smaller than diameter of smallest punctures.

Elytra as in porosus except basal crenulations more poorly developed, submarginal crenulations absent; entire surface minutely reticulate (visible at 80 diameters magnification, not at 40 diameters); interstrial punctures smaller, more numerous; interstriae very slightly wider, surface less irregular; interstrial crenulations near declivity narrower, very slightly higher; declivital scales more abundant, extending to or slightly anterior to base of declivity; setae in interstrial rows very slightly longer, distinctly coarser.

Last visible abdominal sternum never grooved or pubescent as in males of most other Hylurgops species.

Female.- Similar to male except anterior tibiae with five (male with six) socketed teeth; terminal, concealed segments of abdomen only reliable indicator of sex, as in many other species of this subfamily.

Distribution.- Northwest Territories and Montana to California and New Mexico.

CANADA: British Columbia: Aspen Grove, Indian Meadows, Lake Cowichan, Merritt (Midday Valley), Pender Harbor, Princeton, Robson, Spious Creek, Summerland, Trinity Valley, Vancouver, Voght Valley. Northwest Territories: Norman Wells. USA: Arizona: Chiricahua Mts., Coconino N. F., Flagstaff, Jerome, Willians. California: Anderson Valley. Baldwin Lake, Big Bear Lake, Big Pines (Los Angeles Co.), Burney, Carmel, Camp Greeley, Carrville (Trinity Co.), Coffee Creek (Trinity Co.), Del Monte, Facht (Lassen Co.), Hayfork (Trinity Co.), Ilorse Creek, Huckleberry Meadows (Freeman Co.), Lassen N. F., Mammoth, Manzanita Lake (Lassen Co.), Miami R. S. (Mariposa Co.), Monterey, Norval Flats (Lassen Co.), Pacific Grove, Pinecrest, Redstone Station (Tulare Co.), Salt R. S. (Clen Co.), Stevenson Creek (Fresno Co.), Summit Lake (Shasta Co.), Summerdale, Ventura, Willow Rancla,

Yosemite N. P. Colorado: Badger, Boulder, Ft. Collins, Glenhaven, Woodland Park. Idaho: Centerville, Idaho City, Moscow, Priest River, Smith's Ferry, Winchester. Montana: Columbia Falls, Cramer Creek, Darby, Helena, Kalispell. Nevada: Galena Creek (Washow Co.), Kyle Canyon (Clark Co.). New Mexico: Capitan, Cloudcroft, Lincoln N. F., Meek. Oregon: Ashland, Cedar Mt. Grants Pass, Ifood River, Klamath Falls, Prineville, Wallowa N. F. South Dakota: Pine Ridge. Utah: Eureka, Mammoth Mt. Washington: Buckeye, Olympic N. P., Pullman, Quinault, Sunrise Park, Tacoma, Toppenish.
Hosts.-Pinus jeffreyi, P. ponderosa, $P$. radiata, $P$. spp.

Biology.- Evidently very similar to porosus.

Notes.- The above treatment was based on the type series of 86 specimens and on 87 other specimens.

## 6. Hylurgops rugipennis rugipennis (Mannerheim)

Fig. 42
Hylastes rugipennis Mannerheim, 1843, Moskov. Obshch. Isp. Prirody, Otd. Biol. Biul. (Bull. Soc. Imp. Nat. Moscou) 16(2):297 (Syntypes?; Sitka Island, Alaska: lost? Not in Helsinki Mus.)
Diagnosis.- This form intergrades on a narrow zone with r. pinifex (Fitch), from which it may be distinguished by characters summarized in the above key.

Male.- Length 3.6-4.8 mm, 2.44 times as long as wide; color reddish brown.

Frons essentially as in incomptus but with the median carina acute.

Pronotum about 0.9 times as long as wide; widest about a third pronotum length from base, sides strongly arcuate and converging to constriction just behind broadly rounded anterior margin; surface shining, closely, rather deeply, almost uniformly punctured; vestiture very fine, hairlike, usually abraded.

Elytra 1.7 times as long as wide, 2.1 times as long as pronotum; sides almost straight and parallel on basal two-thirds to declivital base, then broadly rounded behind; striae slightly impressed, punctures rather small, deep; interstriae as wide as striae, convex, slightly irregular, punctures fine, confused, a few of them narrowly crenulate, tending to form an indefinite row of tubercles. Declivity steep, convex; striae more narrowly impressed than on disc; interstriae 1 and 9 weakly elevated, 2 feebly impressed; each armed by a row of fine, rather widely spaced granules. Vestiture consisting of short ground cover of broad,
oval scales on declivity, replaced by fine hair on upper declivity and disc (scales very rarely extend anterior to declivital base), and rows of longer, erect, interstrial hairlike bristles.

Female.- Evidently as in male except on abdominal terga.

Distribution.- The Pacific Coast from Alaska to California.

ALASKA: Farragut Bay, Ft. Yukon, Junean, Ketchihan, Kodiak Island, Loring, Sitka, Skagway. CANADA: British Columbia: Aspen Grove, Beaton River, Creston. Glatier, Inverness, Loma, Mainland, Massett (Queen Charlotte Islands). McBride, Merritt (Midday Valley), Mutokatla, Pine Pass, Skidgate, Stanley Park, Taylor Lake, Terrace, Trinity Valley, Vancouver. Yukon: Yukon Terr. USA: California: Carmel. Crescent City, Del Norte, Inverness, McKerrick (Mendocino Co.), Monterey, Pacific Grove. Oregon: Ahlers, Astoria, Breitenbush, Camon Beach, Crater Lake, Detroit, Fogarty, Gold Lake (Willamette N. F.), McMinnville, Newport, North Bend, Otis, Portland, Santiam Pass, Seaside, Taft. Waldport. Washington: Aberdeen, Easton, Eatonville, Forks, Friday Harbor, Hoquiam, Lake Crescent, Metaline Falls, Mt. Adams, Mt. Rainier, Olympic N. P., Quinault, Satsop, Sauk, Sulton.

Hosts.- Picea engelmannii, P. sitchensis, Pinus attenuata, P. contorta, P. monticola, P. muricata, $P$. radiata, and Pseudotsuga menziesii.

Biology. - Specimens in humid areas along the Pacific Coast were taken either from limbs or the bole of fallen trees. The biramous, transverse egg tunnels are of the characteristic hylesinine type that are primarily in the phloem tissues but may engrave the wood slightly. Larval mines wander aimlessly in the phloem tissues and usually are at least partly visible on the inner surface of peeled bark.

Notes.- The above treatment was based on two specimens from Juneau, Alaska, and on 75 other specimens from localities listed above.

Specimens from the coastal areas appear to be anatomically and biologically distinct from those east of the area from the Cascade Mountains to Vernon, British Columbia. Near this line series may fit one form or the other, they may be intermediate in the characters exhibited, or they may contain a mixture of extremes and intermediates of both forms. The zone of intergradation appears to be relatively narrow and except near this line the coastal form represented by the name rugipennis, is easily distinguished from the more
widely distributed inland or eastern form represented by the name pinifex. In view of this narrow zone of intergradation between two otherwise distinct populations, subspecies must be recognized.

## 7. Hylurgops rugipennis pinifex (Fitch) <br> Figs. 39, 42

Hylastes pinifex Fitch, 1858. Trans. New York Agric. Soc, 17:729 (Lectotype, female; New York; U.S. Nat. Mus., 42807, present designation)
Diagnosis.- As mentioned above under $r$. rugipennis, there appears to be intergradation between these forms. Therefore, they are treated as subspecies that can be separated from one another by characters mentioned in the above key.

Male.- Length 3.7-5.2 mm, 2.48 times as long as wide; color reddish brown.

Frons as in $r$. rugipennis. Pronotum as in $r$. rugipennis except more small punctures usually present.

Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; profile as in r. rugipennis; striae slightly impressed, punctures rather small, deep; interstriae as wide as striae, slightly convex, shining, most punctures weakly to moderately crenulate, many crenulations half as wide as interstriae and not oriented to form a uniseriate row. Declivity as in $r$. rugipennis. Vestiture consisting of short, oval scales on entire declivity, often extending to anterior half of disc, usually replaced anteriorly by hairlike setae; and rows of bristles as in $r$. rugipennis.

Fig. 42. Ihylurgops rugipemis subspp., distribution map: r. rugipennis, open squares; $r$, pinifex, solid squares.

Female.- Evidently similar to male except on abdominal terga.

Distribution.- Inland British Columbia to Utah and Colorado then eastward to Nova Scotia and Alabama.

CANADA: Alberta: Cypress Hills, Jasper, Loggan, Waterton N. P. British Columbia: Aspen Grove, Lorna, Marysville, Rolla. Manitoba: Grass River. New Brunswick: Bathurst, Fredricton, McGraw Brook, Plaster Rock, St. Louis, Salmon River. Nova Scotia: Kejimkuyik. Ontario: Algonguin Park, Chalk River, Constance Bay, Ft. Williams, Longlac, Marmora, Petawawa, Quetico Park, Seaforth (Lake Huron), Thessalon, Toronto, Whitefish Point. Quebec: Aylmer, Ft. Coulonge, Hudson, Hull, Lake Memphremagog, Lake Opasatika, Laniel, Rigaud, Quebec, St. Anne de Bellevue. USA: Alabama: Mohile. Arizona: Williams. California: Blancos Corral in White Mts. (Mono Co.). Colorado: Alma, Byers R. S., Dillon, Elk Creek near Fraser (Grand Co.), Estes Park, Fraser. Connecticut: Lichfield. District of Columbia: Washington. Idaho: Coeur d'Alene, Collins, Eagle, Emerald Creek (Clark Co.), Payette N. F., Moscow, Orofino, Pierce, Sand Point, Soda Springs, Utah Co. Maine: Brunswick, Camp Caribou, Monmouth, Norridgewock, Old Town, Paris, Portland, Waldoboro. Massachusetts: Boston, Framingham, Southboro, W. Springfield, Stoneham. Michigan: Eagle Harbor, Grand Island, Gull Lake (Kalamazoo Co.), Marquette, Munsing. Minnesota: Duluth, Itasca Park. Montana: Cabinet N. F., Columbia Falls, Missoula, Sula. New Hampshire: Durham, Franconia, Hanover, Manchester, Webster. New Jersey: Chester, Da Costa. New Mexico: Las Vegas. New York: Buffalo, Caroline, Cranberry Lake, Gloversville, Ithaca, Nassau, Pocono Lake, Syracuse, West Point, Wyandanch. North Carolina: Ashville, Davidson River, Hendersonville, Pink Beds, Pisgah Ridge, Southern Pines. Ohio: Chillicothe. Oregon: Grant Co., Pine. Pennsylvania: N. Bloomfield, Chambersburg, Cooksburg, Mt. Alto, Montebello. Utah: Logan Canyon. Wolf Creek Pass. Virginia: Falls Church. Rixey, Vetch. West Virginia: Crow (Raleigh Co.), Dellslow, Grand Co., Hampshire Co., Monongalia Co., Morgantown, Pendleton. Wisconsin: Lac du Flambeau, Three Lakes. Wyoming: Centennial, Lovell.

Hosts.- Pinus contorta, P. flexilis, P. resinosa, and $P$. virginiana.

Biology. - Basically as in r. rugipennis except the tunnels are constructed in stumps and roots at or below the ground level and only rarely in the bole of fallen trees or logs.

Notes. - The type and 658 other specimens were studied. See the above discussion under $r$. rugipennis concerning intergradation between this widely distributed form and the more restricted form on the Pacific Coast.

This subspecies is very similar to glabratus (Zetterstedt), of Europe and Asia, which it resembles as closely as it does $r$. rugipennis. The minute and often inconsistent differences
between the two forms suggest that geographical races should be recognized. In spite of this, separate names are retained because the differences, though minute, are definite.

The female cotype of Hylastes pinifex Fitch, U.S. National Museum type No. 42807, is here designated as the lectotype of Fitch's species.

## 8. Hylurgops subcostulatus subcostulatus (Mannerheim) <br> Figs. 40.A.8

Hylastes subcostulatus Mannerheim, 1853. Bull. Soc. Imp. Sci. Nat. Moscou 26(3): 239, Holotype, sex?; Kenai Peninsula, Alaska; presumably lost) Hylastes cristatus Mannerheim, 1853, Bull. Soc. 1mp. Sci. Nat. Moscou 26(3):239 Holotype, sex?; Kenai Peninsula, Alaska; presumably lost).
Diagnosis.- As indicated in the above key this is the only American Hylurgops with the alternate declivital interstriae strongly elevated. From about central Arizona and New Mexico northward the elevations are more nearly uniform in height and the tubercles they bear are comparatively small; the population from that point southward is placed in the subspecies alternans.

Male.- Length 3.1-4.2 mm, 2.5 times as long as wide; color dark reddish brown.

Frons essentially as in incomptus except rostrum slightly smaller and transverse impression slightly deeper.

Pronotum 0.90 times as long as wide; widest one-third from base, sides on basal two-thirds strongly arcuate and converging slightly, more strongly one-third from anterior margin, rather narrowly rounded in front; surface unarmed, densely covered by punctures of two sizes, larger ones separated by distances equal to less than diameter of a puncture, smaller ones confined to interspaces and about half as large as larger punctures. Each small puncture bearing a small, ragged scale; a few bristles on lateral margins.

Elytra 1.8 times as long as wide 2.2 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather broadly rounded behind but with posterior outline interrupted by strongly elevated interstriae; striae slightly impressed, punctures deep; interstriae as wide as striae, convex, subcrenulate toward base, odd-numbered
interstriae elevated toward declivity, punctures fine, close, confused, with an indefinite median row of irregularly spaced, fine granules. Declivity rather steep, convex; interstriae 1, 3, 7, and 9 abruptly, strongly elevated, about as high as wide, summit almost uniform except where armed by a row of moderately large, pointed tubercles, 2,4 , 6 , and 8 unarmed. Ground vestiture of abundant, small scales to base; rows of interstrial bristles visible on posterior half, each bristle short, rather stout.

Body commonly covered by an incrustation.

Female.- Evidently as in male except on abdominal terga.

Distribution.- Alaska and Montana to northern Arizona and New Mexico.

ALASKA: Kenai Peninsula. CANADA: British Columbia: Coldwater, Kelowma, Midday Valley, Peachland, Summerland, Vancouver. USA: Arizona: Chiricahua Mts., Coconino N. F., Coronado N. F., Grand Canyon, Huachuca Mts., Kaibab N. F., Lakeside, Prescott N. F., Santa Catalina Mts., Williams. California: Acta, Bass Lake, Big Pines Park, Blacks Mt., Blue Lake, Burney, Charleton Flats, Chester, Dorrington, Fallen Leaf Lake, Grass Valley, Hackamore, Lassen N. F., Mather, Meadow Valley (Plumas Co.), Mineral, Oakland, Pollock Pines, San Diego, Sequoia N. P., Tahquitz (San Juacinto Mts.), Truckee, Walker Mine (Plumas Co.). Colorado: Bailey, Boulder, Estes Park, Evergreen, Glennhaven, Golden, Norwood, Pingree Park, Uncompahgre N. F. Idaho: Athol (Kootenai Co.), Coeur d'Alene, Harpster Grade, Moscow, Potlatch, Smith's Ferry, Tamarack, Westmond, Whitebird. Montana: Hamilton, Sula. New Mexico: Cloudcroft, Lincoln N. F., Mt. Taylor. Oregon: Ashland, Blue Mts., Corvallis, Green Springs (Jackson Co.), Keno, Klamath Co., Santiam Pass, Sisters, Summit Prairie, Warm Springs Indian Reservation. South Dakota: Black Hills, Custer, Hill City, Spearfish. Utah: Ashley N. F., Long Hollow (Dixie N. F.), Mammoth Mt., Sanford Canyon (Dixie N. F.). Washington: Columbia Co., Kooskooskie, Natches, Preston Creek (Wenatchee N. F.). Wyoming: Centennial.

Hosts.- Evidently all species of Pinus and Picea within its range.

Biology.- Most commonly taken in prostrate trees or logs, but it will also breed in erect trees killed by other beetles. It is one of the few bark beetles that breed successfully in sour logs. Presumably the gallery system is similar to that described above for incomptus.

Notes.- The above treatment was based on 420 specimens that agree with material in the U.S. National Museum and in the Canadian National Collection. The original
material on which Mannerheim based subcostulatus and cristatus is missing from the Helsinki Museum and is presumed lost. The descriptions are adequate to characterize this species; however, that of cristatus indicates a size of 1 lin. ( 2.12 mm ), and for subcostulatus $1^{1 / 4}$ lin. ( 2.65 mm ), which is smaller than specimens examined during this study. In view of other measurements given by Mannerheim, discrepancies of this magnitude might be expected.

## 9. Hylurgops subcostulatus alternans <br> (Chapuis) <br> Fig. 42C

Hylastes alternans Chapuis, 1869, Synopsis des Scolytides, p. 22 (Mexico; Brussels Mus.)
Diagnosis.- The population of this species from central Arizona and New Mexico southward has the alternate declivital interspaces more strongly elevated and somewhat inflated at each tubercle arming its summit. The two widely distributed forms intergrade in a narrow belt in northern Arizona and New Mexico.

Male.- Length $3.3-4.4 \mathrm{~mm}, 2.4$ times as long as wide; color dark reddish brown.

This subspecies differs from s. subcostulatus only in details of elytral structure. The elevated declivital intervals are rather strongly constricted in height and width between tubercles; the strial punctures are also distinctly larger.

Female.- Essentially as in male except for the abdominal terga.

Distribution.- Southern Arizona and southern New Mexico to Mexico (state).

MEXICO: Chiapas: 14 km E San Cristóbal, 31-VII-57, J. A. Chemsak. Distrito Federal: Mexico. Durango: 100 km W Durango, 5-VI-65, 2500 m , No. 28, Pinus, S. L. Wood. Guerrero: Omilteme, H. H. Smith. Mexico: 21 km W San Martin de Texmelucan, 14-VII-53, 2800 m , No. 103, Pinus, S. L. Wood.

Hosts.- Evidently any species of Pinus within its range, but most common in $P$. ponderosa and P. leiophylla.

Biology.- Evidently as in subcostulatus, but less commonly taken in prostrate trees or logs; usually in standing, dying trees.

Notes.- The above treatment was based on 12 specimens that agree with Blandford's Biologia Centrali-Americana material.

Because the zone of intergradation between the subspecies of subcostulatus is in an
inconvenient geographical area, and because it is gradual and rather extensive, I have arbitrarily designated all specimens north of the Mexican border as s. subcostulatus and all those south of the border as s. alternans. Actually, those from the southern one-fourth of Arizona and New Mexico clearly are s. alternans, those from the northern one-fourth are s. subcostulatus, and those from the intervening area usually cannot be placed with confidence in either subspecies.

## Genus HYLASTES Erichson

Hylastes Erichson, 1836, Archiv. Naturgesch. 2(1):47 (Type-species: Bostrichus ater Paykull, subsequent designation by Westwood, 18.38. Synops. Gen. British Ins., p. 39, also by Thomson, 1859. Skand. Coleopt. synop. bearb, p. 146)
Diagnosis.- This genus is very closely related to Hylurgops from which some species are separated with difficulty. Characters mentioned in the above genetic key and in the diagnosis of Hylurgops serve to distinguish it.

Description.- Length $2.1-6.0 \mathrm{~mm}$, 2.6-3.2 times as long as wide; color black except reddish brown in two species.

Frons usually with a transverse impression midway between level of antennal insertion and upper level of eves, convex above, flattened or weakly convex below this point, lower area often with a fine, median carina or a median groove. Eye subovate, entire. Antennal funicle 7 -segmented; club conical, basal segment usually longer than others. Pronotum elongate, unarmed. Scutellum small, oval. Crenulations on elytral bases poorly developed, bases not elevated; striae rarely impressed, punctures distinct; interstriae variously sculptured. Declivity convex, steep. Vestiture usually including scales and hair. Third tarsal segments at most emarginate, not bilobed.

Distribution.- The Holarctic realm; 15 species occur throughout the coniferous forests of North and Central America south to Honduras. An additional dozen or more species occur in the coniferous forests of north Africa, Europe, and Asia.

Biology.-All species breed in the phloem tissues in the stumps and roots and occasionally in logs of coniferous trees. The gallery systems of North American species have not been adequately studied, but are similar to those described above for Hylurgops.

## Key to the Species of Hylastes

1. Frons entirely devoid of a median carina; discal interstriae with punctures uniseriate (except fulgidus); small species, less than 3.0 mm (some fulgidus to 3.5 mm )

- Frons with a definite median carina, often restricted to area near epistoma or to central area; punctures of discal interstriae confused (except longicollis); larger than 3.3 mm
2(1). Interspacial areas between pronotal punctures smooth, shining, entirely devoid of reticulation; punctures on discal interstriae confused; anterior tibiae with five to eight socketed teeth; S California and SW Kansas to Michoacán; $2.8-3.5 \mathrm{~mm}$ 1. fulgidus Blackman
- Interspacial areas between pronotal punctures partly or mostly reticulate; punctures on elytral disc usually subcrenulate or granulate, usually uniseriate; anterior tibiae with four to five socketed teeth; smaller species3

3(2). Frons and vertex punctured, interspaces smooth to feebly granulate, median groove feebly indicated or absent; California and Hidalgo to Maryland and Florida; $2.0-2.5 \mathrm{~mm}$
2. tenuis Eichhoff

- Frons and vertex devoid of punctures, coarsely, closely granulate, lower half usually with a conspicuous median sulcus; Texas to North Carolina and Florida; 2.3-2.7 mm 3. exilis Chapuis

4(1). Elytral declivity devoid of scalelike vestiture; body stout, less than 2.6 times as long as wide; pronotum widest on basal fourth; strial punctures rather large, interstriae coarsely sculptured, rather narrowly convex on declivity, declivital
tubercles rather large; posteriorly interstriae 8 higher than 9 ; New Jersey and Florida to E Texas; $3.3-5.0 \mathrm{~mm}$ 4. salebrosus Eichhoff
ber) ;ber); body more slender, 2.8 or more times as long as wide; pronotum widest ator in front of middle; strial punctures usually smaller, interstriae more broadlyrounded, more finely sculptured, declivital tubercles fine5
$5(4)$. Strial punctures on disc subrectangular, noticeably longer than wide, much wider than interstriae; interstrial punctures uniseriate; hairlike setae on elytral declivity more abundant than scalelike setae; California and British Columbia to South Dakota; 3.3-3.9 mm 5. longicollis Swaine

- Strial punctures on disc circular or at least wider than long; interstriae usually at least as wide as striae, their punctures confused; scalelike setae on declivity much more abundant than hairlike setae; last visible female sternum normal, convex, in male medially impressed and ornamented by fine, often dense pubescense; female pronotum normally more slender; larger species
6(5). Premandibular epistomal process large, usually narrowly emarginate, bilobed, lateral apical margins conspicuously elevated, concavity between them continuous with impressed area extending to near antennal insertions, median carina not divided at its lower extremity; elytral vestiture largely hairlike on declivity, scalelike setae sparse or entirely absent; body color reddish brown; Northwest Territories and Alberta to Arizona; 4.8-5.2 mm 6. ruber Swaine
- Premandibular epistomal process sinuate at most, its lateral apical margins not elevated; median frontal carina forked at lower end, a ridge or costa continuing to near lateral apices of epistomal lobe, median portion of lobe hemispherically or subtriangularly impressed or excavated below costae and bearing a specialized tuft of hairlike setae; vestiture on elytral declivity consisting of abundant scales; body color dark brown to black; male sternum 5 flattened or medially impressed and ornamented by numerous setae
7(6). Fore tibia armed by six teeth, basal half of tibia rather slender; hind tibia with two teeth on lateral margin before angle; pronotum not reticulate (except toward margins in porculus); usually smaller than 4.0 mm except those from Mexico
- Fore tibia armed by seven or eight teeth (rarely six), basal half of tibia stout; hind tibia with three or four teeth on lateral margin before angle; pronotum at least partly reticulate in most specimens; usually larger than 4.0 mm12
8(7). Pronotal punctures fine, deep, interspaces averaging about as wide as a puncture; striae, narrower, interstriae about one and one-half times as wide; punctures on head finer, usually regular and not confluent; color black; Mexico; larger than 4.2 mm9
- Pronotal punctures coarse, interspaces averaging about half as wide as a puncture; striae wider, almost as wide as interstriae; frontal area coarsely punctured; brown to black11
9(8). Diseal strial punctures very small, shallow, interstriae three or more times as wide as striae; interstrial punctures almost as large as those of striae; declivital striae slightly impressed, punctures larger and deeper than those of disc, interstriae three times as wide as striae; Hidalgo to Morelos; 4.8 mm
- Discal strial punctures rather coarse, deep, interstriae less than twice as wide as striae; discal punctures of striae at least twice as large as those of interstriae; strial punctures on declivity not larger than those on dise

10(9). Declivital striae feebly or not at all impressed, punctures coarse, deep, about equal in width to interstriae; interstrial tubercles on declivity more widely spaced, separated by distances about equal to width of an interstriae; Arizona and Durango to Mexico; 4.2-4.9 mm
8. mexicamus Wood

- Declivital striae narrowly impressed, punctures fine, widely spaced; declivital interstriae at least three times as wide as striae, tubercles close, spaced by distances equal to less than half width of an interstriac; punctures on head minute; Hidalgo; 4.3 mm 9. niger Wood

11(8). Pronotal surface of interspaces smooth, shining; pronotal punctures smaller, more uniformly distributed; British Columbia and Montana to Guatemala; $3.3-4.0 \mathrm{~mm}$
10. gracilis LeConte

- Pronotal interspaces at least partly reticulate in marginal areas (rarely entirely shining); pronotal punctures larger, more irregularly placed; Manitoba and New Brunswick to Texas and Florida; 3.8-5.0 mm

11. porculus Erichson

12(7). Discal interstriae finely crenulate to declivity; declivital interstriae armed by small, pointed tubercles; pronotum very closely, deeply punctured; Arizona and New Mexico; 4.0-4.6 mm 12. asperatus Wood

13(12). Entire surface of elytra and pronotum minutely reticulate, dull; interstriae tending to be very slightly wider than striae, less strongly convex, the surface less irregular, punctures finer and as much as irregularly three ranked; British Columbia and California to South Dakota and Arizona; 5.1-6.0 mm
13. macer LeConte

- Surface of elytra smooth, shining; interstriae tending to be slightly narrower than striae, more convex and irregular, punctures larger and mostly uniseriate or two-ranked; usually stouter and slightly smaller
$14(13)$. Striae usually wider than interstriae; interstrial punctures rather coarse; reticulation on pronotum usually less evident, punctures larger; female body 3.0 times as long as wide; in Pinus; Alaska and California to W. Montana; 3.8-4.9 mm 14. nigrinus (Mannerheim)
- Striae usually narrower than interstriae; interstrial punctures finer; reticulation on pronotim clearly evident, punctures slightly smaller; female body stouter, 2.8 times as long as wide; Abies; Utah and Wyoming to New Mexico; $4.4-5.5 \mathrm{~mm}$

15. subopacus Blackman

## 1. Hylastes fulgidus Blackman

Hylastes fulgidus, Blackman, 1941. U.S. Dept. Agric. Misc. Pub. 417:18 (IIolotype, female; Las Vegas Hot Springs, New Mexico; U.S. Nat. Mus., 540.35
Diagnosis.- This species is allied to tenuis
Eichhoff, but it may be distinguished by the larger size, by the smooth, shining frons with nongranulate punctures, by the smooth, shining, nonreticulate pronotum having somewhat smaller punctures, and by the more abundant declivital scales. As in tenuis the frons is completely devoid of a median carina.

Female.- Length $2.8-3.5 \mathrm{~mm}, 2.8$ times as long as wide; color black.

Frons shallowly, transversely impressed just below upper level of eves, convex above and slight inflated below this point, transversely impressed just above epistomal margin except at median line; surfate reticulate on lower half, punctures rather fine, close. deep; vestiture inconspicuous.

Pronotum 1.2 times as long as wide; widest near middle, sides moderately arcuate, rather narrowly rounded in front; surface smooth and shining, punctures large, deep, close.
smaller on anterior third; median line obscurely indicated.

Elytra 1.9 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel on basal three-fourths to declivital base, broadly rounded behind; striae feebly if at all impressed, punctures moderately large, deep; interstriae as wide as striae, feebly convex, punctures rather coarse, confused, not at all granulate. Declivity convex, steep; interstriae slightly wider than striae, granules not evident. Discal vestiture hairlike, short, rather abundant; on declivity of rather abundant scalelike ground cover and rows of longer bristles.

Male.- Distinguishable from female only by abdominal terga.

Distribution- California and SW Kansas to Baja California and Michoacán.

USA: Arizona: Cave Creek in Chiricahua Mts., 2I-VI58; Rustler's Park in Chiricabua Mts., 5-VII-40, R. H. Beamer: Huachuca Mts.; Hualpai M., 6-VII-38, J. N. Knull; Prescott N. F., 8-VII-59, Pinus ponderosa. California: Chuchupate R. S. (Ventura Co.), 9-V-59, C. W. OBrien; Mt. Diablo, 15-III-47. R. Coleman; Northfork, 25-III-26; O'Neal (Madera Co.), 16-1II-47, A. T. McClay. Colorado: New Castle, Hopk. US 31408-28. Kansas: Wallace Co. Nevada: Beaver Dam St. Pk. (Lincoln Co.). New Mexico: Cloudcroft, 27-V1-40, flight, R. H. Beamer: Edgewood, B-1296. C. C. Hoff; Gallup; Las Vegas, 9-VII; Los Alamos, 10-II-58, Pinus edulis. MEXICO: Baja California: Sierra San Pedro Martir at La Sanja, 28 -V-58, J. Powell. Chihuahua: La Laja, I6-VII-60, flight, S. L. Wood; 26 km NE San Juanito, 19-VII-60, flight, S. L. Wood. Durango: 50 km SW El Salto, 23-VIl-53, flight, S. L. Wood. Mexico: Amecameca. Michoacán: Mazamitla, 24-VII-53, C. and P. Vaurie. Morelia: Calpulapan. Zacatecas: 6 km W Monte Escondido, 2600 m , flight, R. II. Beamer; "Durango," VII-53.

Hosts.- Pinus edulis, P. ponderosa, and presumably $P$. spp.

Biology.- Unknown; presumably it infests stumps or roots. Evidently most or all the above specimens were taken in flight.

Notes. - The above treatment was based on the holotype and on 49 other specimens.

## 2. Hylastes tenuis Eichhoff <br> Fig. 204

[^1]Hylustes pusilhus Blackman, 1941, U.S. Dept. Agric. Misc. Publ. 417:23 (Holotype, female; Florida; U.S. Nat. Mus., 54036); Wood, 1971, Great Basin Nat. 31:146. Synonymy
Hylastes parvus Blackman, 1941, U.S. Dept. Agric. Misc. Publ. 417:24 (Holotype, female; Williams, Arizona; U.S. Nat. Mus., 54037); Wood, 1971, Great Basin Nat. 31:146. Synonymy
Ihylastes minutus Blackman, 1941, U.S. Dept. Agric. Misc. Publ. 417:25 (Holotype, female; Lake Tahoe, Nevada; U.S. Nat. Mus., 54038); Wood, 1971, Great Basin Nat. 31:146. Synonymy
Diagnosis.- This species is very closely related to attenuatus Erichson, of Europe, from which occasional specimens from the Atlantic Coast states are distinguished with difficulty. Among American species it is allied to fulgidus Blackman, from which it is easily distinguished by characters included in the above key.

Female.- Length 2.1-2.7 mm, 3.0 times as long as wide; dark brown to almost black.

Frons with a weak, transverse impression just below upper level of eyes, convex above and slightly inflated below this point, transversely impressed immediately above epistomal margin except at median line; middle third of median line often narrowly impressed; surface coarsely, rather shallowly punctured, fundus of each puncture reticulate at least on upper half of frons; vestiture inconspicuous.

Pronotum about 1.2 times as long as wide; widest on basal half, sides weakly arcuate, broadly rounded in front; surface reticulate except toward median line, with coarse deep punctures.

Elytra 1.9 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel on basal two-thirds to declivital base, rather narrowly rounded behind; striae 1 weakly, others not impressed, punctures large, deep; interstriae as wide as striae, feebly convex, each bearing a uniseriate row of fine, rounded, setiferous granules. Declivity narrowly convex, slope rather gradual on upper half, steep below; sculpture essentially as on disc. Vestiture consisting of interstrial rows of short, hairlike bristles, somewhat longer on declivity; and, on disc, supplemental rows of scales may be present, usually not more than one row on each interstrial margin.

Male.- Except for abdominal terga consistent differences not apparent.

Distribution.- California, and New York to Hidalgo and Florida.

USA: Alabama: Horn Mt., Mobile, Montomery. Arkansas: Bradley Co. Arizona: Baboguivari Mt. (Pima Co.), Chiricahua Mts., Flagstaff, Hualpai M., Jacob’s Lake, Oak Creek Canyon, Prescott N. F., Williams, Winslow. California: Bass Lake, Big Basin (San Mateo Co.), Carmel, Carrville, Grass Valley, Miami, Mokel Hill (Calavaras Co.), Mt. Laguna (Cleveland N. F.). District of Columbia: Washington, Woodridge. Florida: Lake Placid, Key West, Monticello, Sebring. Georgia: Clayton. Idaho: Nez Perce. Kentucky: Irving (Estill Co.), Knox Co. Louisiana: Bogalusa, Elizabeth. Maryland: Beltsville, Hyattsville, Oldenton, Plumbers Island, Plum Point, Travilah. Massachusetts: Framingham. Mississippi: Ocean Springs. Nevada: Lake Tahoe. New Jersey: Beach Haven. New Mexico: Las Vegas. New York: New York, Yaphank (Long Island). North Carolina: Ashville, Black Mt., Chadbourn, Durham. Gray Beard Mt., Lake Toxaway, Pink Beds, Pishgah Ridge, Southern Pines, Swamanoa Valley, Tryon, Whitesides Mt. (Highlands). Pennsylvania:" Clark's Valley, Cold Springs (Adams Co.), Hummelstown, Mamada Gap, University Park. South Carolina: Aiken, Florence, Myrtle Beach. Tennessee: Chilhowee. Texas: Big Bend. Call. Utah: Zion N. P. Virginia: Camp Pickett, Ft. Monroe, Nelson Co., Virginia Beach, West Point. West Virginia: Kanawha Station, Morgantown, Roncevert, West Sulphur. MEXICO: Hidalgo: Jacala. Mexico: San Rafael.

Hosts.- Evidently any species of Pinus within its range; less commonly from other conifers.

Biology.- Largely unknown, presumably a root-infesting species.

Notes. - The types of tenuis and criticus were examined by J. M. Swaine prior to their loss and compared to material in his collection. The above treatment was based on my material that agrees with Swaine's specimens and that was compared to holotypes of $p u$ sillus, parous, and minutus. The features described by Blackman for the species treated here as synonyms appear to be normal variations. There are numerous minute variations within a series involving the shape of the pronotum, appearance of the elytral surface, and vestiture. Some of these variations result from abrasion. In all, 279 specimens were examined, 88 of them were from the western United States.

## 3. Hylastes exilis Chapuis

Hylastes exilis Chapuis, 1869, Synopsis des Scolytides, p. 20 (Holot ype, sex?: "Nuorlean." presumably New Orleans, Louisiana; Brussels Mus.)
Diagnosis.- This species is distinguished from tenuis Eichhoff by the slightly larger average size, by the rather coarsely granulate
frons and vertex that are devoid of punctures, by the distinct median groove on the frons, and by the very slightly larger (variable) elytral crenulations.

Female.- Length 2.3-2.7 mm, 2.8 times as long as wide; color black.

Frons as in tenuis except transverse impression at middle more distinct, median sulcus on lower half always distinctly impressed, and surface devoid of punctures, rather closely, coarsely granulate above transverse impression, more finely granulate on lower half.

Pronotum and elytra as in tenuis except interstrial crenulations average very slightly larger, slightly confused, often closer (variable).

Male.- Similar to female in all respects; presence of declivital interstrial scales possibly restricted to males.

Distribution.- Texas to North Carolina and Florida.

USA: Alabama: Conecuh, 7-XI-61, P. palustris, E. I. Hazard. Arkansas: Texarkana. 26-III-07, W. D. Pierce. District of Columbia: Washington, V, Hubbard and Schwartz. Florida: Flagler Co., 12-X-7T. P. clliotii, T. H. Atkinson; Lake Placid, 13-VII-48, R. H. Beamer; Lake Worth, I889, L. B. Parker: Sebring, 20-V1-51, at light, S. L. Wood; Vero Beach. 15-11-14, flight, G. G. Ainselle. Louisiana: Elizabeth, VII-IX-67, Pinus taeda. Mississippi: Lucedale, 28-IV-29, H. Dietrich.: Starkville, 19-V-20, M. W. Blackman. North Carolina: Chapel Hill, 28-IV-29, H. Dietrich; Chadbourn. 20-IV-I0, E. G. Smith; Southern Pines, 19-IV-17, A. H. Mantee. South Carolina: Bishopville. 17-IV-61, V. M. Kirk; Myrtle Beach, 22-IV-57. 11-IV-62, V. M. Kirk. Texas: Kirbyville, 2-1II-08, E. S. Tucker.

Hosts.- Pinus elliotii, P. plaustris, $P$. taeda, and probably other $P$. spp.

Biology. - Not recorded. It probably breeds in the stumps and roots of pine trees. Most specimens were collected in flight in pine forests.

Notes.- The above treatment was based on the holotype and on 2I other specimens.

## 4. Hylastes salebrosus Eichhoff

Hylastes salebrosus Eichhoff, 1868 (May). Berliner Ent. Zeitschr. 12:I46 (Lectotype, male: Carolina: L'.S. Nat. Mus., present designation)
Hylastes scobinosus Eichhoff, 1868 (May). Berliner Ent. Zeitschr, 12:146 (Syntypes? sex?: Carolina presumably lost in the Hamburg Musemm.). Ncu Synonymy
Hylurgus scabripennis Zimmermann. 1565 (September). Trans. Amer. Ent. Soc. 2:149 Syntypes: Atlantic States: Mus. Comp. Zool.); Blandford, 1598, Ent. News 9:5. Synonymy

Diagnosis.- This species is not closely allied to any species known to me. It differs from all other Hylastes species in having the elytral vestiture hairlike, scales are entirely absent; punctation of the pronotum is more nearly like the Rhyncolini than Hylastes; and the declivital interstriae are much more coarsely tuberculate than in other Hylastes.

Female.- Length 3.3-5.0 mm, 2.4-2.5 times as long as wide; color black.

Frons weakly, transversely impressed just below upper level of eyes, more strongly, broadly, transversely impressed just above epistomal margin; epistomal lobe poorly developed; median carina rather poorly developed but usually distinct on its upper half; surface rather finely, obscurely punctured on lower half, becoming rather coarsely granulate above.

Pronotum 1.05 times as long as wide, widest at base, sides arcuately converging to weak constriction just behind broadly rounded anterior margin; surface smooth with rather small, deep punctures, their size decreasing on anterior third; spaces between punctures variable but usually slightly less than diameter of a puncture.

Elytra 1.5-1.6 times as long as wide, 1.8 times as long as pronotum; sides very feebly arcuate to declivital base then somewhat narrowly rounded behind; striae impressed, punctures rather small, distinct; interstriae one and one-half times as wide as striae, convex, surface subshining, with transverse lines through irregular, confused punctures, more nearly subcrenulate toward base and declivity. Declivity convex, moderately steep; interstrial crenulations close, tuberculate, in rows. Vestiture largely confined to declivity; short, fine middle row on each interstriae slightly stouter but usually not longer.

Male. - Similar to female except last visible abdominal sternum flattened or weakly impressed toward median line, not convex as in female.

Distribution- - New Jersey and Texas to Florida.

USA: Alabama: Altmore, Mobile. Florida: Biscayne Bay, Catistille, Montacello, Snead, Suwance Springs. Georgia: Atlanta, Clayton, Ionisiana: Bogalusa. Maryland: Beltsville. Mississippi: Lueedale. New Jersey: Lakewood, Sommerset Co. Norif Carolina: Ashville, Camp Pickett, Pink Beds, Pisgah Ridge, Southem Pines, Swannanoa Valley. Tryon. South Carolina: Clemson

College, Florence, Lumber. Texas: Call, Willis. Virginia: Cape Charles, Enterprise, Ft. Monroe, Nelson Co.

Hosts.- Presumably all species of Pinus within its range.

Biology. - This species evidently breeds in stumps or in roots well below ground level. Because newly emerged adults have been taken from seedlings, it is possible that a feeding on green host tissues is necessary for maturation. Adults sometimes are attracted in large numbers to green lumber at sawmills.

Notes.- Two cotypes of salebrosus, a male and a female, in the U.S. National Museum apparently are the only existing specimens of the original series. I, therefore, here designate the first specimen, a male, as the lectotype of salebrosus Eichhoff. A female specimen in the U.S. National Museum received from Eichhoff and labeled as a cotype of scobinosus is from "Tennese" (sic) and cannot be regarded as a member of the original type series; however, because it was examined by Eichhoff it is used as the basis for placing this name in synonymy. In addition to these, 151 specimens were examined during this study.

## 5. Hylastes longicollis Swaine

Hylastes longicollis Swaine. I91s. Dom. Camada Dept. Agric. Ent. Br. Bull 14(2):79 (I folotype, sex?; Atlanta, Idaho; Canadian Nat. Coll., 9246)
Diagnosis. - The structure of the epistomal process, the paucity of elytral scales and the light body color indicate a relationship to ruber Swaine and distinguish these species from other Hylastes. The small size and the large, quadrate punctures distinguish it from ruber.

Female.- Length 3.0-3.9 mm, 2.9 times as long as wide; color moderately dark reddish brown.

Frons with transverse impression just below upper level of eves very poorly developed, subinflated at level of antennal insertion, epistomal margin rather narrowly impressed; epistomal lobe wide, poorly developed, devoid of a pair of elevations extending to median carina; a fine, acutely elevated carina extending on lower half from transverse impression to near base of epistomal lobe; surface rather coarsely, shallowly punctured; vestiture consisting of short hair.

Pronotum 1.22 times as long as wide, widest just in front of middle; sides straight
and diverging slightly on basal half, rather broadly rounded in front; surface smooth, shining, with very coarse, moderately deep punctures, their imer surfaces subreticulate, interstriae equal to less than half diameter of a puncture; median line evident on middle half; vestiture consisting of fine, moderately short hair over entire surface.

Elytra 1.93 times as long as wide, 1.9 times as long as pronotum; sides almost straight and parallel to declivital base, narrowly rounded behind; striae not impressed, punctures coarse, mostly longitudinally subrectangular; interstriae about half as wide as striae, punctures fine, subgranulate on anterior lip, almost uniseriate. Declivity narrowly convex, moderately steep; striae about as wide as interstriae. Vestiture consisting of short, rather fine interstrial hair on dise, becoming stout on declivity and with an indefinite row of slender scales on each margin of each interstriae.

Male.-Similar to female except body evidently a little stouter, with the last visible abdominal sternum slightly flatter and shorter (very indefinite).

Distribution.- British Columbia and Alberta to California and South Dakota.

CaNADA: Alberta: Cypress Hills, I-VI-25, F. S. Carr. British Columbia: Aspen Grove, 23-VI-3.3. Pinus contorta, K. Graham: Cranbrook; Emerald Lake; Creston, 3I-V-56, G. S. Smith; Lorna, 29-VI-24, G. Hopping: Merritt (Midday Valley), 7-VI-25, P. ponderosa. J. Stanley; Pender Harbor, 10-V-28, G. R. Hopping; Terrace; Trinity Valley, I8-V-28, J. R. Howell. USA: California: Giant Forest (Tulare Co.), I9-VII-I5, 3200 m , R. Hopping; Lake Tahoe; Lodgepole Camp (Sequoia), 24-VI-48, A. T. McClay; Meadow Valley (Plumas Co.), 26-VI-30; Miami R. S. (Mariposa Co.), 20-V-42, A. J. Walz; Round Meadow Giant Forest (Tulare Co.); White Cloud Camp (Nevada Co.), 30-V-65, P. Arnaud. Idaho: Coeur dAlene, 20-VI-36, P. monticola, T. O. Thateher; Idaho City, 26-V-70, trap; Kootenai Co., I9-VI-68, trap; Krassel R. S., 14-VI-66, flight. M. M. Furniss; McCall, 14-VI3I, M. A. Cazier; Robinson Lake (Latah Co.), II-VI-53, R. Abbott. Montana: Columbia Falls, I8-V-IO. J. Brunner: St. Regis, 25-V-70, P. contorta, M. D. McGregor. Oregon: Clackamas Co., 25-VII-66; Hood River: Mary's Peak, I9-VI-6I, flight, S. L. Wood; Prineville, VIII-35, $P$. ponderosa, W. J. Buckhorn: Tollgate. 8-VI-31, McLane. South Dakota: Black Hills, Hopk. U'S6:35b, Washington: Mt. Baker N. F., I5-VII-35, A. M. Holland: Quilcane. 26-VI-35, flight. R. L. Fumiss: Olympic N. P., is-Vil-66.

Hosts.-Pinus contorta, P. monticola, P. ponderosa.

Biology.- It has been taken from stumps at or below the ground level.

Notes.- The above treatment was based on my female homotype fron Coeur d'Alene N. F., Idaho, and 129 additional specimens.

## 6. Hylastes ruber Swaine

Hylastes ruber Swaine, 1915. Canadian Ent. 47:367 (Holotype, sex?: Golden, British Columbia, Cana dian Nat. Coll. 9245)
Diagnosis.- This species is rather closely allied to longicollis Swaine, but it is easily distinguished by the larger size, by the smaller, circular strial punctures, and by the confused interstrial punctures.

Female.- Length 4.8-5.2 mm, 2.8 times as long as wide; color reddish brown.

Frons with transverse interocular impression very weak, subinflated near level of antennal insertion, narrowly, transversely impressed immediately above epistomal margin; epistomal lobe wide, rather large, not reinforced by a pair of ridges extending to median carina; median carina acutely elevated from interocular impression to a point just above base of epistomal lobe, its lower end not forked; surface coarsely, closely, rather deeply punctured; vestiture hairlike, short, inconspicuous.

Pronotum 1.12 times as long as wide; widest at or just behind middle, sides arcuate from base to feeble constriction just behind rather broadly rounded anterior margin; surface smooth, shining, punctures coarse, close, their centers subreticulate, interspaces less than half diameter of puncture; punctures on anterior fifth reduced in size, their interspaces here commonly reticulate; median line indicated on about middle three-fourths: hairlike vestiture minute, usually completely abraded.

Elytra 1.8 times as long as wide, 1.9 times as long as pronotum; sides almost straight and parallel on basal three-fourths to declivital base then rather broadly rounded behind; striae feebly if at all impressed, punctures circular, moderately large, deep; interstriae as wide as striae, punctures minute, confused. very finely granulate or subgranulate. Declivity convex, steep, striae moderately impressed; interstriae convex, tubercles larger. Vestiture consisting of minute, semirecumbent hair.

Male.- Similar to female except body evidently slightly stouter and last visible abdominal sternum somewhat flattened and shorter.

Distribution.- Northwest Territories and Alberta to Arizona.

CANID.A: Alberta: Bow River. British Columbia: Cranbrook, 2t)-Vi-20, G. Carrett; Creston, 15-V-53, 2I VI-5.5. G. S. Smith; Copper Mt., 20-V-2S, (; S. Smith; Kokance Mt., London Hill Mine on Bear Lake, 2I-VII03: Trinity Valley, 15-V-27. W. Mathers: Vancouver, 20-VI-39. H. B. Leech; Vernon, 20-V'1-39. II. B. Leeech. Northwest Territories: Aklavik, 20-VIII-30, O. Bryant. U'SA: Arizona: IIanagan Camp (Greenlee Co.), 12-1'II$6\rangle$, D. E. Bright. Idaho: Idalso City, 26-V-7I, trap, M. M. Furniss, Kootenai Co., II-VII-68, trap, M. M. Furniss: Krassel. V-58, Douglas fir, M. M. Furniss, McCall; Rocky Point (Benewah Co.), 23-VI-64, R. W. Portman: Moscow, 30-V-31, P. Rice. Montana: Columbia Falls: Kilispell, 15-V-20. Oregon: Bear Springs (Wapinita), 30-VI-4I. K. M. Feneler; Clear Lake. 15-VI-45. K. M. Fender: Clackamas Co., 25-VII-66; Hood River, 20-V; Pacific City, 2]-VII-42, K. M. Fender; Tollgate. Washington: Buckeye; Easton; Omak, 7-VII-66; Satsop River, Vlll-32; Seattle, S-V-60; Walla Walla, 9-V-36, E. W. Jones.

Host. - Pseudotsuga menziesii.
Biology.- Evidently restricted to the stumps and roots of the host tree. The habits evidently are similar to those of other Hylastes.

Notes. - The above treatment was based on the holotype and on 134 other specimens.

## 7. Hylastes flohri (Eggers)

Hylurgops flohri Eggers. 1926, Ent. Blatt. 26:166 (Holotype, female; Mexico; Berlin Zool. Mus.) Hylastes flohri: W'ood, 1966, Creat Basin Nat. 26:24.

Diagnosis.- This species is rather closely allied to mexicanus Wood, from which it is rather easily distinguished by characters summarized in the above key.

Female.- Length $4.8 \mathrm{~mm}, 2.8$ times as long as wide; color black.

Frons with interocular transverse impression shallow, broad, rather well developed; weakly inflated at level of antennal insertion, rather broadly impressed above epistomal margin; surface rather coarsely, closely, rather deeply punctured; median carina fine, weakly elevated from interocular impression to base of epistomal lobe, where it forks (obscure) and elevations continue to poorly developed epistomal lobe; vestiture minute, obscure, hairlike.

Pronotim 1.1 times as long as wide; widest at base, sides on basal two-thirds almost straight and converging slightly toward rather broadly rounded anterior margin; sur-
face smooth and shining, punctures small, deep, reduced anteriorly, interspaces irregular but usually at least equal to diameter of a puncture; median line not evident; glabrous.

Elytra about 1.8 times as long as wide, 1.8 times as long as pronotum; outline as in mexicanus; striae 1 weakly others not impressed, punctures very small, not clearly impressed; interstriae three to four times as wide as striae, surface irregular, shining, punctures moderately abundant, fine, confused, almost as large as those of striae. Declivity convex, rather steep; striae rather weakly impressed, punctures small but much larger than on disc; interstriae subshining, about three times as wide as striae, each with a row of fine, rounded granules almost in uniseriate rows. Vestiture confined to declivital interstriae, consisting of small, moderate to sparse seales and median rows of equally short, coarse hairlike setae.

Distribution.- Hidalgo to Morelos.
MEXICO: Distrito Federal: Km 43 on Highway 95. Hidalgo: 30 km E Tulaneingo, I0-VII-67, 2100 m , Pinus, S. L. Wood. Mexico: Amecameca, Parque Zoquiapan. Morelos: Km 44 on Ilighway S-082.

Host.- Pinus sp.
Biology.- Two specimens were taken just entering the phloem tissues on the lower side of a pine $\log 40 \mathrm{~cm}$ in diameter. It is presumed their habits resemble those of other Hylastes.

Notes. - The above treatment was based on the female holotype and on nine other specimens. The labels on the type include "Sal.," "Salizar, Rohr,"' "Coll. J. Flohr."

## 8. Hylastes mexicanus Wood

Hylastes mexicanus. Wood, 1967. Great Basin Nat. 27:36 (IIolotype, female; 62 km west Toluca, Mexico, Mexico; Wood Coll.)
Diagnosis. - The very fine, deep, pronotal punctures and the narrower striae distinguish this species and flohri Eggers from other representatives of the genus. This species is also distinguished from flohri by characters summarized in the above key.

Female.- Length 4.3-4.5 mm, 2.8 times as long as wide; color black.

Frons convex, with a weak, transverse impression between eyes and more strongly impressed just above epistoma; median carina inconspicuous, more strongly elevated below
level of antennal insertion, continuing dorsad as a fine line to interocular impression, lower end forked; surface smooth and shining above, rather dull below, very finely, deeply, closely punctured; vestiture minute, inconspicuous, convering entire surface.

Pronotum 1.1 times as long as wide; sides widest on basal third, but almost parallel to a point just anterior to middle then broadly, evenly rounded to anterior margin; surface smooth and shining, with punctures fine, deep, close, separated by distances about equal to their own diameters; median line not evident; glabrous.

Elytra 1.9 times as long as wide, 1.9 times as long as pronotum; sides straight and parallel on basal half, then increasingly arcuate to rather narrowly rounded posterior margin; striae 1 moderately, others weakly impressed, punctures small, deep; interstriae as wide as striae, feebly convex, subshining, punctures rather coarse, close, deep, confused, their diameters often only slightly smaller than those of striae. Declivity convex, steep; striae 1 weakly impressed, as wide as interstriae, punctures coarse, deep; interstriae each with a row of fine tubercles; surface reticulate. Vestiture confined to declivity, stout, consisting of small scalelike setae except for median rows of equally short hairlike bristles on each interstriae.

Male.-Similar to female except frons narrower, and last visible abdominal sternum impressed medially and pubescent.

Distribution.- Arizona and Durango to Mexico (Estado).

USA: Arizona: Carr Canyon, Cochise Co., 23-VII-68, D. E. Bright. MEXICO: Durango: 16 km W El Salto, VII-64, flight, J. B. Thomas. Mexico: 62 km W Toluca, I5-VII-5.3, 2600 m , Pinus, S. L. Wood. Morelos: Tres Marias, Wickham.

Biology.-Specimens were collected at the base of a large pine tree. Presumably they have habits similar to other Hylastes.

Notes. - The above treatment was modified from the original description based on the type series of 69 specimens, and on about 300 other specimens from the same locality.

## 9. Hylastes niger Wood

Hylastes niger Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(I):7 (Holotype, male; 3I km E Tulancingo, Hidalgo, Mexico; Wood Coll.)

Diagnosis.- This species is distinguished from mexicanus Wood by the narrowly impressed declivital striae with the punctures much smaller, and by the much more closely spaced granules on the declivital interstriae.

Male.- Length $4.3 \mathrm{~mm}, 2.7$ times as long as wide; color black.

Frons and pronotum as in mexicanus except frons less distinctly reticulate, pronotum with punctures distinctly smaller.

Elytra as in mexicanus except strial punctures much smaller, interstriae twice as wide as striae on disc, almost three times as wide on declivity; declivity not as steep; interstrial granules on declivity much more closely spaced, spaced by distances equal to less than half width of an interstriae.

Female.- Similar to male except frons more finely punctured; anterior discal area of pronotum with punctures reduced to almost obsolete.

Distribution.- Hidalgo.
MEXICO: Hidalgo: 30 km E Tulancingo, 10-V1l-6i. 2100 m . No. I85, Pinus, S. L. Wood: Zacualtapan.

Biology.- Two specimens were taken from the same new tunnel on the lower side of a $\log 60 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the holotype, allotype, and eight other specimens.

## 10. Hylastes gracilis LeConte Fig. 43

Hylastes gracilis LeConte, 1868, Trans. Amer. Ent. Soc. 2:I74 (Lectotype, female; Tahoe Valley, California: Mus. Comp. Zool.. 958, designated by Wood, 197I, Great Basin Nat. 3I:145.)
Hylastes vastans Chapuis, 1869. Synopsis des Scolytides. p. 17 (Holotype, female; Mexico; Brussels Mus.): Wood, 1971, Great Basin Nat. 3I:I45. Synonymy
Hylastes longus LeConte, 1876, Proc. Amer. Philos. Soc. 15:388 (Holotype, female; Colorado; Mus. Comp. Zool.); Wood, 1972, Great Basin Nat. 32: 195. Synonymy
Hylastes nitidus Swaine, I917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. I4(1):19 (Holotype, sex?; Las Vegas. New Mexico; Canadian Nat. Coll.); Wood, 1971, Great Basin Nat. 3I:145. Synonymy
Hylastes asper Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(I):19 (Holotype, female; Larimer Co.. Colorado: Canadian Nat. Coll. 9244); Wood. 1975, Great Basin . Nat. 35:22. Synonymy
Diagnosis.- This small, widely distributed. common species is distinguished
from allied species by the dark brown color, by the size, and by other characters summarized in the above key. Occasional specimens are distinguished from fulgidus Blackman with difficulty.

Female.- Length 3.3-4.0 mm, 3.0 times as long as wide; color dark brown.

Fronx convex, interocular, transverse impression weak, weakly subinflated at level of antennal insertion immediately above narrow epistomal impression; surface shining, closely, coarsely, deeply punctured; median carina usually extending from interocular impression to base of epistomal lobe, fine, acutely elevated to very obscure, in some specimens either dorsal or ventral half may be obsolete; vestiture short, rather abundant, stout.

Fig. 43. Hylastes gracilis: Dorsal aspect. (After Bright and stark 1973:147.)

Pronotum 1.19 times as long as wide; widest at middle, sides weakly arcuate, almost parallel on basal two-thirds, not constricted before broadly rounded anterior margin: surface smooth, shining, punctures moderately coarse, deep, separated by interspaces equal to not more than diameter of a puncture (usually less); glabrous.

Elytra 1.9 times as long as wide, 1.9 times as long as pronotum; sides almost straight and parallel on basal three-fourths to declivital base, then rather narrowly rounded behind; striae 1 weakly, others not impressed, punctures coarse, deep; interstriae as wide as striae, almost smooth, punctures fine, almost uniseriate. Declivity convex, rather steep; strial punctures slightly larger than on disc; interstriae weakly convex, each armed by a row of fine granules. Vestiture consisting of fine hair on disc, becoming moderately abundant, slender scales on declivity.

Male. - Similar to female except very slightly stouter, and with last visible abdominal sternum impressed and pubescent in median area.

Distribution.- British Columbia and South Dakota to (probably) Honduras.

CANADA: British Colmmbia: Creston, Merritt (Midday Valley), Newgate, Oliver, Summerland. USA: Arizona: Chiricahua Mts., Flagstaff, Graham Mts., Grand Canyon; Hanagan Camp (Creenlee Co.), Lakeside, McNary, Oak Creek Canyon, Prescott N. F., Vail Lake, Willians. California: Numerous localities from every county. Colorado: Estes Park, Maniton, Montrose. Idaho: Avon, Krassel. Montana: Ashland. Nebraska: Glen. Nevada: Baker, Beaver Dam St. Pk. (Lincoln Co.), Lake Tahoe. New Mexico: Alhuquerque, Bandelier, Capitan Mts., Cloudcroft, Las Vegas, Lincoln N. F. Jimenez Springs, Santa Fe. Torrance Co., Ute Park. Oregon: Bear Springs, Lakeview, Quartz Mt. (Lake Co.), Rankin. South Dakota: Black Hills, Piedmont. Washing ton: Blewett, Maple Valley, Mt. Adams, Peshastin Creek. MEXICO: Baja Califormia: Laguna Hansen at Sierra Juarez. Chiapas: San Cristobal. Durango: El Salto, La Cindad, Las Boregas. Hidalgo: Tulancingo. GUATEMALA: Cerro Calel.

Hosts.-Pinus edulis, P. monophylla, P. jeffreyi, P. ponderosa, P. pseudostrobus; Abies concolor has been recorded, but it is not a normal host.

Biology.- Usually taken from the phloem tissues of stumps and roots of the host. Evidently the habits are similar to other Hylastes.

Notes.- The above treatment was based on types of gracilis, vastans, longus, asper,
nitidus, and 296 other specimens. All definitely fall within the limits of this somewhat variable species.

Though a majority of the specimens from a given geographical area fit the above description rather well, occasional individuals exhibit frontal characters that are rather different in one or more respects. When adequate material was available these were easily recognized as local variants; however, when only the extreme variants were available there was some hesitation about their correct identity.

## 11. Hylastes porculus Erichson Fig. 46

Hylastes porculus Erichson. 1836, Archiv Naturgesch. 2:49 (Holotype, male; Pennsylvania; Berlin Zool. Mus.)
Hylastes carbonarius Fitch, 1858, Noxious lasects of New York, Rpt. 4:730 (Holotype, female; Allbany, New York: U.S. Nat. Mus., 42S08); LeConte, 1876. Proc. Amer. Philos. Soc. 15:389. Synonymy Hylurgus caternosus Zimmermann, 1868, Trans. Amer. Ent. Soc. 2:149 (Lectotype, male; Atlantic states: Mus. Comp. Zool., present designation): Eichhoff, 1896. Proc. U.S. Nat. Mus. 18:606. Synonymy
Hylastes granosus Chapuis. 1869, Synopsis des Scolytides, p. 17 (Syntypes; Southern and Middle states; Brussels Mus.): LeConte, 1876, Proc. Amer. Philos. Soc. 15:389. Synonymy
Hylastes scaber Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):18 (Holotype, sex?: Virginia; Canadian Nat. Coll., 9326); Eggers. 1934, Ent. Nachrichtenbl. 8:25. Synonymy
Hylastes suainei Eggers, 1934, Ent. Nachrichtenbl. 8:25 (Holotype, male; Frater, Ontario; U.S. Nat. Mus.); Blackman. 1941, U.S. Dept. Agric. Misc. Pub. 417:11. Synonymy
Hylastes webbi Blackman, 1941, U.S. Dept. Agric. Misc. Pub. 417:10 (Holotype, female; Elmore, South Dakota; U.S. Mus., 54033); Wood, 1971, Great Basin Nat. 31:146. Synonymy
Hylastes canadensis Blackman, 1941, U.S. Dept. Agric. Misc. Pub. 417:15 (Holotype, female: Aweme. Manitoba; U.S. Nat. Mus., 54034); Wood. 1971. Great Basin Nat. 31:146. Synonymy
Diagnosis.- This species is intermediate between gracilis LeConte and nigrinus (Mannerheim). A summary of characters that distinguish it from the former species is included in the above key. From nigrinus it is distinguished by the more abundant pronotal punctures, by the smoother discal interstriae, by the longer frontal carina, and by the tibial armature.

Female.- Length 3.8-5.0 mm, 2.7 times as long as wide; color black.

Frons as in gracilis, with interocular impression usually more pronounced; frontal carina acutely raised from interocular impression to base of epistomal lobe.

Pronotum 1.13 times as long as wide; widest at or immediately anterior to middle, sides on basal half weakly arcuate, rather broadly rounded in front; surface obscurely reticulate over entire surface in material from eastern areas, at hasal or other margins in those from northwestern area of distribution; punctures coarse, somewhat irregular in size, separated by distances one-half to equal diameter of a puncture; glabrous.

Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; outline as in gracilis; striae 1 weakly, others feebly or not at all impressed, punctures coarse, deep; interstriae narrower than striae, somewhat convex, smooth, but undulating, punctures fine, confused. Declivity convex, steep; basically as on disc; tubercles minute if present. Vestiture consisting of sparse, almost scalelike bristles on declivity.

Male.-Similar to female except usually stouter and last visible abdominal sternum medially impressed and pubescent.

Distribution. - Manitoba and New Brunswick to Texas and Florida.

CANADA: Manitoba: Aweme. Treeshank, Winnepeg. New Brunswiek: Fredricton. Ontario: Frater, Petawawa Res.. Sudbury. Quebee: Berthier, Wright. L'SA: Alabama: Cleborn Co., Montgomery. Arkansas: Bradley Co. Connecticut: "Ct." Distriet of Columbia: Washington. Florida: "Fla." Georgia: Clayton, Dallas, Habersham Co., Mt. Airy, Savannah. Louisiana: Bogahsa. Naine: Orono, Paris. Maryland: Bladenshurg, Clen Echo, Hyattsville. Travilah. Massaehusetts: Petersham. Mieh igan: Marquette, Whitefish Point. Minnesota: Itascad Park, W'hitewater St. Pk. New Hampshire: Durham. Hanover, Henniker. New Jersey: Atlantic City, Cape May, Five Mile Beach, Lakewood, Malaga, Newfoundland. New York: Jamaica (Long Island), Warrensburg. North Carolina: Asheville, Durham, Harnett Co., Lake Toxaway, Pink Beds, Southem Pines, Tryon. Pennsylvania: Mt. Alto, University Park. South Carolina: Florence, Greenville. South Dakota: Ehmore. Temessee: "Temm," Texas: Call. Virginia: Cape Charles, Falls Church. Ft. Monroe, Gloucester Co., Mt. Vernon, Nelson Co. West Virginia: Dellslow, Greenbriar, Hardy Co., Raleigh Co., Randolph Co. Wisconsin: Washington Co.. Wood Co.

Hosts.- Presumably all species of Pinus within its range.

Biology.- As in other species of the genus.

Notes. - The above description was based on the holotypes of porculus ( 4.0 mm ), canadensis, scaber, swainei, and webbi and on 199 other specimens. The first syntype of Hy lastes cavernosus Zimmermann, a male previously designated by a type label, is here designated as the lectotype of Zimmermann's species.

In all probability the populations designated here as nigrinus (Mannerheim) and asperatus Wood intergrade with porculus and, therefore, represent no more than subspecies. The data presently available are not adequate to properly determine their status.

## 12. Hylastes asperatus Wood

Hylastes asperatus Wood, 1975, Great Basin Nat. 35:24 (Holotype, female: New Mexico; Wood Coll.)
Diagnosis.- This is a difficult species to recognize. The pronotal punctures are irregular in size, as in porculus, but much closer; the discal interstriae are slightly wider than allied species, more nearly convex, and very finely, closely crenulate (usually not clearly apparent unless the light source is posterior to the specimen).

Female.- Length $4.0-4.6 \mathrm{~mm}, 2.7$ times as long as wide; color dark brown.

Frons as in gracilis with interocular impression moderately strong, fine, low carina evidently always extending from this impression to base of epistomal lobe where it forks as in related species.

Pronotum 1.2 times as long as wide; sides on slightly more than basal half straight and

Fig. 44. Hylastes migrimus: Galleries in Donglas-fir roots: A-B, maturation feeding; C-C, egg galleries. (After Zethner-Msfler and Rudinsky 1967:904.)
parallel, rather broadly rounded in front; surface subshining, indications of reticulation obscure but usually visible at high magnification toward anterior or basal areas, punctures coarse, very close, deep, irregular in size in some specimens, interspaces usually equal to less than one-fourth diameter of a puncture; median line partly impunctate, not raised; glabrous.

Elytra 1.8 times as long as wide, 1.8 times as long as pronotum; outline as in gracilis; striae moderately impressed, punctures rather coarse, deep; interstriae as wide as striae, punctures moderately coarse, close, confused, their anterior margins elevated into fine, crenulate, transverse ridges of variable height (this character approached in allied species, but not to this degree). Declivity convex, steep; striae narrowly, deeply impressed, punctures somewhat obscure; interstriae about twice as wide as striae, armed by very fine, confused tubercles. Vestiture confined to declivity, scalelike.

Male.-Similar to female except slightly stouter, and last visible abdominal sternum medially impressed and pubescent.

Distribution.-Arizona and New Mexico.
USA: Arizona: Hanagan Camp (Greenlee Co.), 12-VII65, D. E. Bright: Santa Catalina Mts., 5-VIII-68, flight, D. E. Bright. New Mexico: Alma (Carton Co.), Las Vegas, VIl-52, 2300 m, F. H. Snow; Sierra Blanca Mt., Hopk. US72IG.

Hosts.- Not recorded, presumably Pinus.
Biology.- Presumably this species breeds in stumps and roots of the host tree.

Notes.- The type series 29 species was examined.

This might possibly be a geographical race of porculus Erichson.

## 13. Hylastes macer LeConte Fig. 45

Hylastes macer LeConte, 1868, Trans. Amer. Ent. Soc. 2:175 (Lectotype, male; California; Mus. Comp. Zool., 963, present designation)
Diagnosis.-Although allied to nigrinus (Mannerheim) and subopacus Blackman, this species is unique in having the entire surfaces of the pronotum and elytra finely reticulate; it is also the largest American Hylastes.

Female.- Length 5.1-6.0 mm, 3.0 times as long as wide; color black.

Frons essentially as in asper.

Pronotum 1.3 times as long as wide; widest at middle, sides rather strongly, almost uniformly arcuate from base to just before broadly rounded anterior margin; entire surface finely reticulate, punctures rather small, shallow, irregular in size and outline, interspaces averaging distances slightly less than diameter of a puncture; median line partly impunctate, not elevated; glabrous.

Elytra 1.9 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel on basal half, then converging slightly to a point just behind declivital base, narrowly rounded behind; striae 1 moderately, others feebly impressed, punctures moderately large and deep; interstriae as wide as striae, weakly convex, reticulate, sculpture slightly irregular, punctures fine, close, confused. Declivity convex, gradual above, rather steep on lower half; striae and strial punctures a little more strongly impressed than on disc; interstriae convex, armed by small, confused granules. Vestiture confined to declivity, scalelike.

Male.-Similar to female except usually slightly stouter, and last visible abdominal sternum medially impressed and pubescent.

Distribution.- British Columbia and South Dakota to California, Arizona, and Colorado.

CANADA: British Columbia: Cranbrook, Creston, Kootenay N. P., Merritt (Midday Valley), Oliver. USA: Arizona: Chiricahua Mts., Flagstaff, Kaibab N. F., Williams. California: Alpine, Alta Sierra (Kern Co.), Amador Co., Bass Lake, Calistoga, Camp Wolfboro (Calaveras Co.), Carmel, Carrville, Cedarville, Chester, China Camp, Colony Mill (Tulare Co.), Deer Creek (Tahama Co.), Echo Lake, Emigrant Gap, Fresno, Hamburg, Hat Creek, Hobart Mills, Huckleberry Meadow, Incline (Mariposa Co.), Kings Canyon, Lake Tahoe, La Moine, Lassen N. P., Lomo, Meadow Valley (Plımas Co.), Meyers, Miami R. S., Millwood (Fresno Co.), Modoc Co., Mt. St. Helena, Nevada City, Northfork, Pinecrest, Placer Co., Plaskett Station (Glenn Co.), Sand Flat, San Juacinto Mts., Silver Creek (Alpine Co.), Siskiyou Co. Sterling, Summerdale, Trinity Co., Woodford (Alpine Co.), Yosemite N. P. Colorado: Estes Park, Ft. Collins. Idaho: Granite, Idaho City, Krassel, Moscow, Potlatch, Robinson Lake (Latah Co.), Slate Creek R. S. (Idaho Co.), Smith’s Ferry, Wallace. Montana: Columbia Falls, Helena. Nebraska: Pine Ridge. Nevada: Baker, Kyle Canyon (Clark Co.) Oregon: Anthony Lake, Beatty, Cave City, Crater Lake N. P., Deming Creek (Klamath Co.), Gardiner, Glenada, Klamath Falls, Meacham, Ochoco N. F., Pinehurst, Prineville, Tollgate, Wallowa Lake. South Dakota: Black Hills. Utah: Escalante, Bryce Canyon N. P., Zion N. P. Washington: Blewett, Buckeve, Easton, Ft. Lewis, Glenwood, Grand Coulee, Mt. Rainier, Seattle, Skammani Co., Vaughn, Walla Walla.

Hosts. - Pinus spp., less commonly from Picea engelmannii.

Biology.- Galleries are constructed in phloem tissues of stumps and roots of the host tree.

Notes.- The first specimen in the LeConte series, a male from California, has long been regarded as the type of this species; I here designate that specimen as the lectotype of macer. The lectotype and 682 other specimens were examined.

## 14. Hylastes nigrinus (Mannerheim) Figs. 18, 19, 20, 45, 46

Hylurgus nigrinus Mannerheim, 1852, Bull. Soc. Imp. Sci. Nat. Moscou 25:356 (Holotype, female: Sitka Jsland, Alaska; Helsinki Mus.)
Hylastes nigrinus: LeConte, 1868, Trans Amer. Ent. Soc 2:174
Hylastes yukonis Fall. 1926. Pan-Pacific Ent. 2:207 (Holotype, male; White Horse, Yukon Territory: Mus. Comp. Zool.); Wood, 1957, Canadian Ent. 89: 396. Synonymy

Fig. 45. Hylastes macer: Lateral aspect. (After Bright 1976:206.)

Diagnosis.- This species is very closely related to porculus. The differences are obscure and characters may intergrade when additional material becomes available. This species has the pronotal punctures slightly smaller and more closely placed, and the punctures on the declivital striae are smaller. Because nigrinus, asperatus, and porculus replace one another geographically, it is entirely possible that they are only subspecies of one another. Additional material from intermediate localities must be examined before their status can be clarified.

Female.- Length $3.8-4.9 \mathrm{~mm}, 2.7$ times as long as wide; color black.

Frons as in porculus.
Pronotum 1.13 times as long as wide; widest at or just behind middle, sides rather weakly arcuate from base, rather broadly rounded in front; surface smooth and shining, usually with areas of obscure reticulation at
base or other marginal areas, punctures rather coarse, deep, close, interspaces almost always equal to less than half diameter of a puncture; median line largely impunctate; glabrous.

Elytra 1.8 times as long as wide, 1.9 times as long as pronotum; outline as in proculus; striae feebly impressed, punctures coarse, deep; interstriae as wide as striae, weakly convex, surface irregular (undulating), smooth, shining, punctures small, close, confused. Declivity as in porculus except striae usually slightly narrower and deeper than interstriae (striae slightly wider than interstriae in porculus). Vestiture largely confined to declivity, consisting of interstrial scales as in related species.

Male.-Similar to female except usually slightly stouter, and last visible abdominal sternum medially impressed and pubescent.

Distribution.- Alaska and California to W Montana.

Fig. 46. Hylastes spp., distribution map: nigrinus, solid circles; subopacus, solid squares; porculus, open circles.

ALASKA: Sitka Island. CANADA: Alberta: "Laggan." British Columbia: Atlin, Bear Lake, Bowser, Kokanee Mit., Lorna, Lumberton, Merritt (Midday Valley), Nelson, North Bend, Pender Harbor, Port Renfrew, Sidney, Summerland, Victoria. Northwest Territories: Ft. Smith. Yukon: White Horse. USA: California: Ben Lomond, Chester, Fieldlorook, Ft. Seward, Happy Camp (Siskiyou Co.), Hat Creek, Lagunitas, Lamoine (Shasta Co.), Los Angeles, Los Gatos, Meadow Valley (Plmmas Co.), McCloud, Mill Valley, Mt. St. Helena, Quincy, San Mateo Co., Santa Rosa, Sequoia N. P., Shasta N. F., Summit Road (Santa Cruz Co.). Idaho: Coeur d'Alene, Harvard (Latah Co.), Priest River, St. Maries (Benewah Co.). Montana: Lindburg Lake at Condon. Oregon: Amity, Astoria, Baker Creek, Bear Springs R. S., Camon Beach, Clackamas Co., Clatsop Co., Clear Lake, Corvallis, Dayton, Detroit, Eugene. Forest Grove, Gardiner, Golden, Griffin Creek (Jackson Co.), Hillsboro, Hood River, Keno, Klamath Falls, Lane Co., Manzanita, Mary's Peak, McMinmville, Medford, Mosier, Mt. Hood, Neotsm, Newberg, Pacific City, Paradise Park, Portland. Sand Lake, Silver Creek Falls, Sisters, St. Helens, Scappoose, Sweet Basin, Tillamook, Trail, Veronia, Waldport, Wending, Winema N. F., Yamhill Co. Washing. ton: American Lake, Beaver. Bothel. Chase Lake (Snohomish Co.), Cranberry Creek (Mason Co.), Eatonville, Elva, Everett, Glenwood. Green River Gorge. Lewis and Clark St. Pk., Lester, Moclips, Mt. Adams, Mt. Baker, MIt. Rainier, Ocean Park, Olympia, Olympic N. P., Parkland, Port Blakely, Puyalhup, Quillayute, Quinault, Seattle, Sequim Bay St. Pk., Skye, Sol Duk Sp.. Tacoma, Vantage, Vanghn, Wending, Winslow.

Hosts.- The species of Pinus, Picea, Pseudotsuga, Tsuga, Larix, and Abies in approximately that order of preference.

Biology.- This common species infests the phloem tissues of stumps and roots of the host trees. The biramous adult galleries score the wood very lightly; evidently they most commonly run transverse to the grain of the wood. The larval mines appear to wander aimlessly through the phloem tissues.

Notes. - The types of nigrinus and yukonis and 675 other specimens were examined.

There are some minor geographical variations in the population, but none of these exhibit trends toward those found in the geographical replacement species porculus in the eastern United States and asperatus in the southern Rocky Mountains. Until some indication of intergradation is found it appears best to retain these forms as valid species.

## 15. Hylastes subopacus Blackman Fis. 46

Hylastes subopacus Blackman, 1941, U.S. Dept. Agrie. Misc. Pub. 417:9 (Holotype, male: Capitan Mountains, New Mexico, U.S. Nat. Mus., 540.32

Diagnosis.- This species is very dosely related to nigrimus and replaces that species geographically in Utah, Colorado, and New Mexico. Its size, habits and structure suggest that it is a distinct species, not a geographical race. It is distinguished by characters summarized in the above key.

Female.- Length $4.4-5.5 \mathrm{~mm}, 2.6$ times as long as wide; color black.

Frons as in nigrinus except inflated area on lower half more poorly developed, epistomal impression somewhat more extensive.

Pronotum 1.1 times as long as wide; sides almost straight and parallel on basal half. then arcuately converging to broadly rounded anterior margin; surface minutely. obscurely reticulate, punctures moderately small, rather deep, close, interspaces equal to less than half diameter of a puncture; middle half of median line impunctate; glabrous.

Elytra 1.6 times as long as wide, 1.8 times as long as pronotum; outline similar to nigrinus; striae feebly impressed anteriorly, stronger behind, punctures rather coarse, deep; interstriae slightly wider than striae, punctures small, confused, finely subasperate. Declivity as in nigrinus, striae slightly more strongly impressed, punctures small: interstrial tubercles usually smaller.

Male.-Similar to female except slightly stouter, and last visible abdominal sternum medially impressed and pubescent.

Distribution.- Utah and Wyoming to New Mexico.

USA: Colorado: Argentine Road; Silverton, VILI-55. New Mexico: Capitan Mts., 17-VHent, J. L. Webb. Utah: Brighton, VII-1S, Hubhard and Schwart: Logan Canyon, 6-VII-48, and SS-\1-49. Abies lasiocarpa. S. L. Wood; Wolf Creek Pass, 17-VI-60, Abies lasiocarpa, S. L. Wood. Wyoming: Brooks Lake: Medicine Bow Range 1929.3200 m .

## Host.- Abies lasiocarpa.

Biology.- Tunnels were constructed in phloem tissues of stumps and roots of large, dying, standing trees. The biramous parental tunnels tended to be transverse and scarcely engraved the wood. Larval mines usually were exposed on peeled bark and appeared to wander at random. Both larvae and adults were present on the three occasions when observations were made.

Notes.- The male holotype, both male paratypes, and 19 other specimens were examined for this study.

# Tribe HYLESININI 

Hylesinen Erichson, 1836, Archiv Naturgesch. 2:46 (Type-genus: Ihylesinus Fabricius, 1801)
Phioeotrupidae Chapuis. 1866, in: Lacordaire, Hist. Nat. Insectes, Coleopt. 7:357 (Type-genus: Phloeotrupes Erichson, 1836)
Puloeobom Blandford, 1893, Trans. Ent. Soc. London 1893:426 (Type-genus: Phloeoborus Erichson, 1836)
Dactylopalpi Blandford, 1893. Trans. Ent. Soc. London 1893:426 (Type-genus: Dactylopalpus Chapuis, 1869)
Hylastivides Nüsslin, 1912, Naturwiss. Zeitschr. Forst- und Landwirtschaft 1912:273 (Type-genus; Hylastinus Bedel. 1888)
Alviphagins Murayama, 1963, Studies in the scolytid fama of the northern half of the Far East, V, Hylesininae, p. 29 (Type-genus: Ahiphagus Swaine, 1918)

Anatomical features. - The frons is obscurely to moderately sexually dimorphic, the eye is entire to feebly sinuate on the anterior margin, the antennal funicle is 6 - or 7 -segmented, the club is symmetrical and conical to moderately flattened, with the sutures indicated, the procoxae are contiguous to rather narrowly separated, the pronotum is armed by a few asperities (except in Hylastinus), the metascutellar area is separated from the postnotum by a distinct suture, and the sutural groove on the mesal surface at the base of the elytra is interrupted by a series of interlocking nodules and cavities.

Biological features.- All species are monogamous, all American species except Phloeoborus are phloeophagous. Their parental tumnels are either biramous or, if monoramous, there is a well-developed turning niche near the entrance tunnel. Eggs are deposited in niches. Larval mines usually follow a definite course away from the parental gallery and rarely cross one another. Phloeoborus is xylophagous and appears to have a symbiotic relationship with fungi, although not in a mycetophagous sense.

Taxonomy.- This tribe is somewhat intermediate between the Hylastini and Tomicini. Of the three native genera, two appear to have been derived from Eurasia (Alniphagus and Hylesinus) and one from South America (Phlocoborus). Most of the genera in this tribe occur in the Old World. The American genera of Hylesinini are easily recognized; those from other parts of the world may be distinguished with great difficulty.

## Genus HYLAStinus Bedel

Hylastinus Bedel, 1888, Aun. Soc. Ent. France, Hors Ser. 6:388 (Type-species: Ips obscurus Marsham, monobasic)
Diagnosis.- This genus is not closely allied to other American genera. It is easily distinguished by characters summarized in the above key to genera and in the diagnosis of obscurus below.

Description.- Length $2.0-2.5 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown. Frons as described below for obscurus; eye entire, elongate; antennal scape elongate, funicle 7 -segmented club with three sutures, 1 and 2 septate. Scutellum small, slightly depressed; bases of elytra armed by a single row of overlapping crenulations extending to striae 9. Declivity convex, steep; sculpture conservative. Vestiture hairlike. Prothoracic intercoxal piece moderately wide, margined laterally in front of coxae by an acutely elevated ridge extending from coxa to anterior margin. Third tarsal segments bilobed.

Distribution.- Four European species are known, one of which has been introduced into North America.

Biology.- The adults bore in the roots of leguminous hosts, where they rear their broods.

## Hylastinus obscurus (Marsham)

Ips obscurus Marsham, 1803, Entomologia Britanica, p. 57 (Syntypes?; Type locality unknown, probably England; not located)
Hylastes obscurus: Chapman, 1869, Ent. Mon. Mag. 6:6. Synonymy

Hylastinus obscurus: Bedel, ISSS, Ann. Soc. Ent. France, Hors. Ser 6:388. Synonymy
Dermestes trifolii Müller, 1803. Mem. Soc. Sci. Dep. du Mont. Tonerre 1:47 Syntypes? Central Europe: not located); Chapman, 1869, Ent. Mon. Mag. 6:6. Synonym!
Hylesinus crenulatus Duftschmid, 1825, Fama Austriaca 3:10.4 Syntypes? Linz, Austria: depository not located); Hagedorn, 1910, Coleopt. Cat. 4:12. Synonymy
Hylurgus piceus Stephens, 18:30, Illustrations of British Entomology 3:365 (Syntypes: London, England: British Mus. Nat. Hist.): Hagedorn, 1910, Coleopt. Cat. 4:12. Synonymy
Hylurgus fuscescens Stephens, 1830, llustrations of British Entomology 3:365 (Syntypes?; London, England: British Mus. Nat. Hist.); Hagedorn, 1910, Coleopt. Cat. 4:12. Synonymy
Hylastinus kroaticus Fuchs, 1912, Morphologische Studien uber Borkenkäfer. II. Die europäischen Hylesinen, p. 39 (Syntypes?; Warasdin, Croatia: not known to me): Schedl, 1964, Riechenbachia 2:210 (Synonymy; as croaticus)
Hylastinus pilosus Eggers. 1944, Ent. Blätt. 40:140 (Holotype, male?? Algiers; U.S. Nat. Mus., 59131): Schedl, 1960, Ent. Mitt. 31:162. Synonymy
Diagnosis.- This species, introduced from Europe, is not closely related to any native American species, although it superficially resembles Hylurgopinus rufipes (Eichhoff), with which it commonly is confused in collections. It is most easily distinguished from rufipes by the presence of a strongly elevated ridge extending from the lateral margin of the fore coxae to the anterior margin of the pronotum; it also has a conspicuous, transverse, interocular impression and it completely lacks a sharply defined premandibular epistomal lobe.

Female.- Length $2.0-2.5 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown.

Frons convex, with a rather well-developed, transverse, interocular impression then slightly inflated to level of antennal insertion, transversely impressed just above epistomal margin, epistomal lobe rather well developed; surface coarsely reticulate, with coarse, close, very shallow obscure punctures; vestiture hairlike, short, inconspicuous.

Pronotum 0.9 times as long as wide; widest about one-third length from base, sides rather strongly arcuate on basal two-thirds, rather shallowly constricted just before broadly rounded anterior margin; surface coarsely, deeply, closely punctured, fundus of most punctures obscurely reticulate, interspaces very narrow, shining; vestiture hairlike, moderately long, rather abundant.

Elytra 1.4 times as long as wide, 1.9 times as long as pronotum; sides almost straight and parallel on basal two-thirds to declivital base, rather broadly rounded behind; basal margin of each elytron armed by a single row of moderately large, overlapping crenulations extending to base of striae 9; striae weakly impressed, punctures large, deep; interstriae distinctly narrower than striae, feebly convex, punctures rather fine, part of them sub)crenulate, becoming tuberculate toward declivity. Declivity convex, rather steep; striae slightly narrower, interstriae more strongly convex than on disc; each interstriae armed by a row of rather fine, pointed tubercles. Vestiture consisting of coarse, hairlike, interstrial setae about equal in length to diameter of a strial puncture, and median rows of interstrial hair about twice as long as more abundant ground vestiture.

Male.- Apparently distinguished from female only by differences in terminal abdominal terga.

Distribution.- North Africa, south and central Europe to the Caucasus, British Columbia and Ontario to California and Georgia.

CANADA: British Columbia: Bear Hill, Grindrod. Sidney. Ontario: Prince Elward Co., Toronto. Trenton. USA: California: Nevada City. Connecticut: Stamford. Georgia: Waddington. Idaho: Boise, Caldwell, Chilco, Council. Hubbs Butte, Moscow, Murtaugh, Parma, Weippe, Wilder. Indiana: Bem, Ft. Wayne, LaFayette. Oakville, Wabash Co. Maryland: Hagerstown. Massachusetts: Forest Hills. Michigan: Agricultural College. Washtenaw. New Hampshire: Durham. New Jersey: Greenwood Lake, Hackettstown, Hohokus, Irvington. New York: Bridgeport. Dimdee, Ehmyra, Ithaca, Mecklensburg, Newport, Onondaga Co.. West Point. Ohio: Columbus. Delaware Co., Hartsgrove, Holgate, Lorain Co., Rock Creek. Scotio Co., Westville. Oregon: Bethany, Canby, Comelius, Corvallis, Dayton, Dever, Forest Grove, Marshfield, McMinntille, Molalla, Portland. Ridgeway, Roseburg, Salem, Scio, Sheridan, Scappoose. St. Helens, Taft. Utah: Benson. Garden City, Honeville, Spring Lake in Utah Co., Tremonton. Washington: Blaine, Bothell. Cedar Itt. Chase Lake, Conway, Duvall, Evans Creek (King Co.), Gardiner, Loveland, Manchester, Mt. Vermon, Port Townsend, Pullman, Renton, Sutton. Vancouver.

Hosts.- Trifolium spp. preferred, although Medicago, Melilotus, Lathyrus, and Vicia species are acceptable.

Biology. - Overwinters as young adults or larvae in infested clover roots in the ground. New adult tumnels are constructed in the spring in unthrifty plants. The galleries are
basically of the biramous type with eggs deposited in niches along the margins. The larvae mine at random through the root tissues. Pupation occurs during late summer. There is one generation each year.

Notes.- The above treatment was based on 216 American specimens that were compared to several European specimens identified by Eichhoff, Eggers, etc.

## Genus HyLesinus Fabricius

Hylesinus Fabricius, 1801, Syst. Eleuth. 2:390 (Typespecies: Hylesinus crenatus Fabricius, subsequent designation by Westwood, 1838, Synopsis of the genera of British Insects, p. 39)
Ficicis Lea, 1910, Proc. Roy. Soc. Victoria, n. s., 22:147 (Type-species: Ficicis carians Lea, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:122); Schedl, 1936. Proc. S. Australia Mus. 5:521. Synonymy
Leperisinus Reitter, 1913, Wiener Ent. Zeit. 32(Beiheft):41 (Type-species: Bostrichus fraxini Panzer $=$ B. carius Fabricins, subsequent designation by Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):70): Wood, 1978, Great Basin Nat. 37:511. Synonymy
Ficiphagus Murayama, 1958, Yamaguti Univ. Facul. Agric. Bull. 9:930 (Type-species: Ficiphagus goliathoides Murayama $=$ Iylesinus porcatus Chapuis, original designation): Schedl, 1962, Beitr. Ent. 12:486. Synonymy
Diagnosis.-American species are easily distinguished by the scalelike vestiture and the moderately ascending abdomen. Alniphagus is the most closely allied American genus.

Description.- Length $1.8-4.0 \mathrm{~mm}$, 1.8-2.0 times as long as wide; color dark brown, densely clothed by various mixtures of white, tan, brown, or black scales to form characteristic color patterns; frons in male
transversely impressed to strongly concave, devoid of median carina, female frons flattened to convex, a median carina often present. Eye oval, anterior margin weakly sinuate. Antennal scape elongate; funicle 7segmented; club elongate, slightly flattened, slightly asymmetrical, marked by three aseptate sutures. Pronotum wider than long, anterolateral areas usually armed by several crenulations. Scutellum rather small, round. Elytral bases armed by a long row of closely set, overlapping crenulations; striate; declivity convex, moderately steep, abdomen ascending almost halfway to meet apex of elytra. Vestiture largely scalelike.

Distribution.- North America to Guatemala; Europe and Asia to Australia; eight species occur in America, about 30 species in the Eastern hemisphere.

Biology.- The monogamous species cut transverse biramous egg galleries that engrave the wood rather deeply. The larvae mine primarily in the phloem tissues parallel to the grain of the wood. With few exceptions the host plants belong to the genus Fraxinus. The winter is passed in the adult stage outside of the brood gallery system in individual feeding and hibernation tunnels constructed in green bark of living trees. Blackman (1922a:63) estimated that as many as three generations may occur in one season.

Notes.- The genus Hylesinus Fabricius has been rather seriously abused in taxonomic literature, primarily because of the extreme diversity of species presently included in it and in several genera closely allied to it. An obvious need for a complete reevaluation of these genera exists.

## Key to the Species of Hylesinus

1. Male frons transversely impressed on less than lower half, moderately convex above; setae on propleural area rather slender, usually simple, almost never divided into more than two parts; setae on abdominal sternum 5 long and slender, essentially hairlike

- Male frons concavely excavated from epistoma to upper level of eyes; setae on propleural area broad, usually divided into three or more filaments; setae on abdominal sternum 5 stout, largely scalelike (hairlike in californicus and guatemalensis)
2(1). Pronotum devoid of asperities in anterior or anterolateral areas; frontal vestiture very short; North Dakota and Ontario to Vermont and Tennessee; 3.2-4.0 mm

1. pruinosus Eichhoff

- Pronotum armed by several coarse asperities in anterolateral areas, usually supplemented by a row of small submarginal ones in anteromedian area; frontal pubescence moderately long; smaller species

3(2). Frons with fine, shallow punctures in both sexes, male entirely devoid of a median carina; discal interstrial crenulations rather fine; discal scales on elytra smaller, averaging one-fourth as wide as interstriae; South Dakota and Kansas to Quebec and New Jersey; 2.0-3.0 mm
2. aculeatus Say

- Frons with coarse, moderately deep punctures in both sexes, lower half of male frons with a low, poorly developed, median carina; discal cremulations much larger; discal scales on elytra larger, averaging one-third as wide as interstriae; Oregon to California; 2.5-3.3 mm

3. oregonus (Blackman)

4(1). Smaller; declivital interstriae 2 as wide as 1 or 3, not conspicuously depressed, armed on upper half by a few small granules; median line on female frons weakly impressed; median row of scales on each interstriae not longer, usually not erect anywhere on elytra; Saskatchewan and Colorado to Ontario; 1.9-2.4 mm
4. criddlei (Swaine)

- Larger; declivital interstriae 2 much narrower than 1 or 3 , or strongly impressed or both, devoid of granules; female frons carinate (except guatemalensis); median row of scales (or hair) on some interstriae erect and conspicuously longer than ground cover

5(4). Scales on mature specimens black and white with a few tan; female frontal carina acute, more than half as long as frons; interstriae 9 and 10 with vestiture scalelike, none noticeably longer than ground cover; declivital interstriae 2 narrowly convex, bearing one row of scales at middle of declivity

- Scales on mature specimens brown and tan or white; female frons if carinate, carina very short, subtuberculate, confined to lower half; interstriae 9 and 10 with some slender setae at least twice as long as ground scales; declivital interstriae 2 impressed (slightly convex in some females) bearing at least two staggered ranks of scales

6(5). Smaller; scales on basal half of interstriae 9 and 10 more slender. mostly two to four times as long as wide; scales on erect median row of each interstriae only slightly longer than ground cover; black scales usually cover at least 70 percent of elytral surface; Penusylvania and New Jersey to Missouri; 1.8-2.3 mm
5. fasciatus LeConte

- Larger; scales on basal half of interstriae 9 and 10 almost as broad as those in other areas, usually less than twice as long as wide; scales on erect median row of each interstriae conspicuously longer than ground cover; black scales usually cover less than 50 percent of elytral surface; SW Texas and Durango to Puebla: 2.3-2.9 mm

6. mexicanus (Wood)

7(5). Male frons much less strongly concave, female frons more distinctly impressed but not concave, a median carina present on lower half in both sexes: erect interstrial setae on declivity more widely spaced, slender, about four to eight times as long as wide, setae in ground cover on 1-3 similar, erect setae never present on 2; Mexico; Fraxinus uhdei; 3.8-4.2 mm 7. aztecus Wood

- Male frons more strongly concave, never with a median carina, female more distinctly convex, a carina present or not; erect interstrial setae on declivity on 1 and 3 very close, very broad, each about one to four times as long as wide. some ereet setae always present on 2 in female (rare in male)

8(7). Female frons with a short, rounded, prominent carina just below middle; male frons more narrowly, not uniformly concave; elytral scales in ground cover much larger, about one-third as wide as interstriae; Oregon and North Dakota to Chihuahua and Texas; $2.0-3.1 \mathrm{~mm}$
8. californicus (Swaine)

- Female frons flat, entirely devoid of a median carina; male frons broadly, uniformly concave; elytral scales in ground cover much smaller, about one-fifth as wide as interstriae; Guatemala: 2.4-3.1 mm

9. guatemalensis (Wood)

## 1. Hylesinus pruinosus Eichhoff

Hylesinus pruinosus Eichhoff, 1865, Berliner Ent. Zeitschr. 12:149 (Syntypes?: Amerique Boreale; lost with Hamburg Mus.)
Diagnosis.- This species is very closely allied to aculeatus Say, but it may be distinguished by the larger size, by the coarser frontal punctures, by the absence of pronotal asperities, and by the very coarse, uniseriate, interstrial crenulations that are consistently as tall as neighboring scales.

Male.- Length 3.2-4.0 mm, 2.0 times as long as wide; color very dark brown, with a variegated pattern of light and dark scales.

Frons as in aculeatus except slightly more convex and punctures distinctly larger. Pronotum as in aculeatus except asperities in anterolateral areas small to obsolete. Elytra as in aculeatus.

Female.- Similar to male aculcatus except differing by characters noted above for male.

Distribution.- North Dakota, Ontario, and Vermont to Tennessee and Virginia.

CANADA: Ontario: "Ontario"; Ridgeway. USA: IIlinois: Urbana, 26-IV-08; Webster; "N. Ill." Indiana: Columbus, 26-IX-20. Kentucky: Lexington, 4-VIII-58. Michigan: Detroit. Missouri: St. Louis. New Hampshire: Webster. New York: Bear Momntain, 13-VIII-48; Buffalo; Ellenville, VIII-41, Fruxinus; Ithaca. North Carolina: Tryon. Hopk. US 262Ia, 3631a, 3656a. North Dakota: Richland Co.. 27-V-71, W. J. Brandvik. Pemnsylvania: "N. Cumberland"; "Pa." Tennessee: "Tenn." Vermont: Highgate. Virginia: "Va, V-30."

## Hosts.- Fraxinus.

Notes.- The above treatment was based on 30 specimens. Their identity was based on specimens determined by Blackman, Schwarz, and Swaine and on the original description.

This species evidently is rare and poorly represented in collections. It is very similar to some of the variants on the northwestern margins of the distribution of aculeatus and it is not at all impossible that it could be nothing more than an extreme morphological variant of aculeatus. Additional specimens and
field notes are necessary to clarify its taxonomic status.

## 2. Hylesinus aculeatus Say

Itylesinus aculeatus Say, 1824, J. Acad. Nat. Sci. Philadelphia 1:322 (Syntypes?: Missouri; evidently lost)
Hylesinus imperialis Eichhoff, 1868, Berliner Ent. Zeitschr. I2:149 (Syntypes; Wisconsin and Georgia; lost with Hamburg Mus.): Wood, 1973. Great Basin Nat. 33: 178. Synonymy
Lesperisinus cinereus Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1): 15 (Lectotype, female: Hudson, Quebec: Canadian Nat. Coll., designated by Bright, 1967, Canadian Ent. 99:676); Wood. 1957, Canadian Ent. 89:399. Synomymy
Diagnosis.- This common, variable, widely distributed eastern species is allied to varius (Fabricius), of Europe, to the American pruinosus Eichhoff, and to oregonus (Blackman). From the two latter species it is distinguished by characters summarized in the above key. From the former it is easily distinguished by the smaller size, by the lighter color, and by the different frontal sculpture in both sexes.

Male.- Length $2.0-3.0 \mathrm{~mm}, 1.9$ times as long as wide; color dark brown, with a variegated pattern of light and dark scales.

Frons flattened from just below upper level of eyes to just above epistoma, then gradually ascending to epistomal margin, lateral margins weakly elevated on lower third; surface reticulate, almost reticulate-granulate, finely punctured; a very feeble, median carina on lower half; vestiture of coarse, moderately abundant hair of moderate length over entire surface.

Pronotum 0.72 times as long as wide; widest at base, sides arcuately converging to distinct lateral constriction immediately behind broadly rounded anterior margin; crenulations in anterolateral areas moderately large, rarely reduced, a low, submarginal row usually extending to median line; surface minutely reticulate-granulate, punctures moderately large, close, somewhat obscure;
median line indicated one-third pronotum length from base; closely covered by nonoverlapping scales, each scale subcircular at base, subtriangular in anterior area; dark scales form diamond pattern on median third from anterior to posterior margins, lateral margins also dark.

Elytra 1.4 times as long as wide, 2.1 times as long as pronotum; sides very feebly arcuate, subparallel on slightly less than basal two-thirds, rather broadly rounded behind; basal margins, each armed by about 15 crenulations, striae narrowly impressed, punctures rather obscure; interstriae twice as wide as striae, base of 2 armed by about a dozen submarginal crenulations, 3 by about 6,4 by about 3 , and 5 by about 2 submarginal crenulations; interstriae each armed by a moderately confused row of narrow, low crenulations, each shorter than length of a scale, general surface obscured by scales. Declivity moderately steep, convex; interstriae 2 impressed but still convex, tubercles on 3 and 9 slightly larger than on disc, $1,3,7$, and 9 usually appearing slightly elevated. Vestiture scalelike, scales as wide as long, about onefourth as wide as an interstriae, most of those near and on declivity with an elevated median crest; a median row of scales on interstriae 1 and 3 often erect and very slightly longer (less than 1.5 times) than ground cover; light scales in patches, usually comprising 50 to 60 percent of total, occasionally dark scales entirely absent.

Female.-Similar to male except frons weakly convex, obscure median carina longer; pronotal crenulations usually larger and more numerous.

Distribution.- South Dakota and Quebec to eastern Kansas and North Carolina.

CANADA: Manitoba: Aweme. Dauphin, Morden, Winnipeg. Nova Scotia: Lawrencetown. Ontario: Chalk River, Ottawa. Petawawa Res., Prince Edward Co. Quebec: Aylmer, Hemmingford, Isle Perrot, Lake Memphremagog, Ste. Anne de Bellevie, St. Hilaire. USA: Arkansas: Blythville. Colorado: Fort Collins. Connecticut: Bethlehem. Chaplin, Cornwall, Stamford. District of Columbia: Washington. Illinois: Chicago, Macoml. Indiana: "Indiana." Iowa: Aınes, Iowa City. Kansas: Ft. Scott, Norton, Partridge, Riley Co., Salina, Topeka. Louisiana: Frenier, New Orleans, Tallulah. Maine: Lovel, Paris, South Hope, Orono, Wales, Yarmouth. Maryland: Plummers Island. Massachusetts: Charlemont, Commington, Framingham, Hopedale, Lawrence. Petersham, Stoughton, Westhorg. Michigan: Detroit, East Lansing, Pittsfield Twp. in Washtesaw Co.

Minnesota: Buffalo State Park. Mississippi: Agricultural College. Nebraska: Broken Bow, Omaha. New llampshire: Durham, Weloster. New Jersey: Boonton, Clemonton, Clen Cardner, Orange Mts., Peterson, South Mommtain. New York: Buffalo, Checktown. Ellenville, Ithaca, Ogdensburg, Patchin, Scarsdale, Syracose, Utica, West Point. North Carolina: Tryon. North Dakota: Bottenean, Cass Co., Fargo. Regent, Richland Co., Roosevelt N. P. Ohio: Bowling Green. Clinton Co., Colmmbus. Franklin Co., Tiffin. Oklahoma: Payne Co. Pennsylvania: Castle Rock, Clarks Valley, Easton. Harrisburg, Milford, North Cumberland, Pecks Pond, Philadelphia, Philmont, Swarthmore, Wyoming. South Carolina: Bateshurg, Clemson, Ferguson. South Dakota: Mclleury Co. Tennessee: Memphis. Texas: Dallas. Virginia: Falls Church. West Virginia: Kanawah Station, Monongalia, Randolph Co.

Hosts.- Fraxinus americana and F. spp.
Biology.- The bole, limbs, and larger branches are selected for attack where transverse, biramous, parental galleries deeply engrave the surface of the wood. According to Blackman (1922a:62) the transverse length of the complete gallery systems he studied in Mississippi varied from 2 to 6 cm and averaged 4 cm . The larval mines follow the grain of the wood and normally do not cross one another. The young adults do little if any feeding before they emerge from the brood host. Evidently feeding tunnels in green bark are not formed between succeeding summer generations, but they are formed by overwintering beetles. About two months were required to complete a generation in Mississippi.

Notes.- The above descriptions were based on LeConte's series of aculeatus, which was either part of Say's series or compared to it; on LeConte's series of imperialis, which apparently included an Eichhoff specimen; on the type series of cinereus Swaine; on the Schwarz, Hopkins, and Blackman series of aculeatus; and on more than 700 other specimens. A specimen labeled "N.Y.; Cornell Lot. 3 Sub. 5; Hylesinus imperialis Lec. homotype" (the identification label is in Swaine's hand) is a female of californicus and does not match either of LeConte's series. Because the types of both aculeatus and imperalis apparently were lost, LeConte's specimens appear to be the only existing specimens that were either part of the type series or compared to the types of the Say and Eichhoff descriptions.

## 3. Hylesinus oregonus (Blackman)

Leperisimes oregonus Blackman, 1943, Proc. U.S. Nat. Nus. 94:396 (Holotype, female; Forest Grove, Oregon; U.S. Nat. Mns., 56574
Diagnosis. - This species is closely related to aculcatus Say, but it may be distinguished by characters summarized in the above key.

Male.- Length 2.5-3.3 mm, 2.0 times as long as wide; color dark brown, with a variegated pattern of dark brown, yellow, and pale scales, dark scales predominating.

Frons as in aculeatus except carina very slightly higher, punctures much larger and deeper, and vestiture finer.

Pronotum 0.73 times as long as wide; as in aculeatus except submarginal row of crenulations usually not complete to median line, surface more coarsely, deeply punctured, and scales larger.

Elvtra 1.5 times as long as wide, 2.1 times as long as pronotum; as in aculeatus except striae very slightly wider, interstrial crenulations averaging slightly less numberous and higher, scales larger, wider, each scale a third as wide as an interstriae, fewer of them strongly keeled; dark brown scales comprise about half of total, yellow and pale scales about equally abundant.

Female.- Similar to male except frons convex on upper three-fourths, carina slightly longer and higher.

Distribution. - Oregon to California.
U'SA: California: Ililts, I8-1 -33, Ash, Panl Rice. Oregon: Corvallis, 24-1'-31, 6-X-3I, 15-VII-41, Fraximus oregana, J. Schuh; Eugene; Forest Grove, 18-I-19. Fraxinus: McMinmille; Philomath: Mclane; Portland, 26-VH, C. E. Wood, 14-VIH-34, F. oregona, F. P. Keen; St. Helens, Hopk. USII7, Fraxinus, A. D. Hopkins; Scappoose.

Host.- Fraxinus latifolia.
Biology.- Evidently indistinguishable from aculeatus.

Notes.- The above descriptions were based on the holotype and on 153 other specimens. This appears to be a rare species; its distribution along the Pacific Coast probably is much greater than available records indicate.

## 4. Hylesinus criddlei (Swaine)

Leperisimus criddlci Swaine, 191s, Dom. Canada Dept. Agric: Ent. Br. Tech. Bull. 14(2): 72 (Holotype. male; Aweme, Manitoba: Canadian Nat. Coll. $92.51)$

Diagnosis.- This is the most distinctive and also the most difficult American species of the genus to characterize. Its small size, the comparatively simple sculpture of the elytral declivity, and the presence of a weak, median, frontal impression, rather than an elevation, serve to distinguish it.

Male.- Length $1.9-2.4 \mathrm{~mm}, 2.0$ times as long as wide; color dark brown, with a variegated pattern of dark brown, yellowish tan, and pale scales, pale scales usually predominate.

Frons rather abruptly, concavely impressed above epistoma, impression extending to upper level of eyes at least in median area, lateral margins subacutely elevated on lower third; surface minutely reticulate; vestiture consisting of moderately abundant, coarse, rather long, subplumose setae.

Pronotum 0.71 times as long as wide; widest on basal third, sides rather weakly arcuate and converging slightly on basal half, then abruptly rounded and converging to moderate constriction just before broadly rounded, subemarginate anterior margin; surface reticulate, obscurely punctured, with several coarse asperities in anterolateral area, a marginal row of asperities extending almost to median line on anterior margin; scales usually not overlapping, rather large, broad over most of surface, narrower in front, color pattern as in aculeatus.

Elytra 1.5 times as long as wide, 2.1 times as long as pronotum; outline as in aculeatus; dise as in aculeatus except submarginal crenulations smaller, interstrial crenulations narrower, more nearly uniseriate. Declivity convex, moderately steep; interstriae 1,3 , and 9 weakly elevated, 2 almost flat, as wide as 1 or 3 and bearing four indefinite ranks of scales. Vestiture consisting of overlapping interstrial scales, each scale as wide as long, almost a third as wide as interstriae; an oceasional scale on declivity ereet and slightly longer than ground vestiture; light scales usually predominate, tan scales least abundant.

Female.- Similar to male except frons convex on upper three-fourths, median line weakly impressed; asperities on pronotum slightly larger.

Distribution.- Saskatchewan and Colorado to Quebec.

CANADA: Manitoba: Aweme, 31-V11-15, Ex. No. 8178, N. Criddle. Ontario: Port Colbome, 1-VIII-34, D. Gray; Ridgeway, A. II. Kilman. Quebec: Cap Rouge, 15-V-71; Gaspé, 25-VI-37, G. Gautier: Montreal, 12-VII-33, J. I. Beaulne. Saskatchewan: St. Hubert Mission, 14-LX43, Fraximus, P. A. Mullie. USA: Colorado: Denver, 3-V1-49, F. americana; Ft. Collins, VII-52, F. americana, T. O. Thatcher; Laport, 6-III-50, T. O. Thatcher. Iowa: Lake Okoboji, 17-VI, L. L. Buchanan. Kansas: Riley, V'117. Popeno. Michigan: Detroit. Minnesota: Laverne, VIII-37, Ash, H. R. Dodge; Ramsey Co., 8-V-36, H. R. Dodge. North Dakota: Emmons Co., McHenry Co., 13-VI-70, trap, A. D. Tagestad; Pierce Co., 10-V1-71; Ramsey Co., 31-VII-70, F. pennsyluanica, A. D. Tagestad. South Dakota: Millbank, 19-1X-99, F. americana, J. M. Aldrich.

Host.- Fraxinus americana, F. pennsylvanica.

Biology.- Apparently as in aculeatus.
Notes. - The above descriptions were based on the holotype and on 146 other specimens.

## 5. Hylesinus fasciatus LeConte

Hylesinus fasciatus LeConte, 1868, Trans. Amer. Ent. Soc. 2:170 (Holotype, male; York Co., Pennsylvania; Mus. Comp. Zool., 973)
Diagnosis. - The black and white scale pattern and the uniseriate rows of scales on at least part of declivital interstriae 2 clearly distinguish this species and mexicanus (Wood) from other American representatives of the genus. From mexicanus it is distinguished by characters summarized in the above key.

Male.- Length $1.8-2.3 \mathrm{~mm}, 1.8$ times as long as wide; color almost black, with black and white scales, black scales predominating.

Frons rather broadly, deeply concave from epistoma to slightly above upper level of eves, median line very feebly elevated; lower third of lateral margins rather broadly rounded; surface minutely reticulatesubgranulate, punctures rather fine, obscure; vestiture of moderately abundant, rather short, subplumose setae.

Pronotum 0.70 times as long as wide; widest at base, sides arcuately converging to very broadly rounded anterior margin; surface minutely reticulate-granulate, finely, closely obscurely punctured; anterolateral areas each bearing about a dozen coarse asperities, marginal row on median half obsolete; median line indicated on most of posterior half; scales rather large, broad
posteriorly, rather slender anteriorly; white scales largely restricted to posterolateral areas.

Elytra 1.3 times as long as wide, 2.2 times as long as pronotum; outline and basal margins essentially as in aculeatus; striae rather narrowly impressed, punctures rather obscure; interstriae slightly less than twice as wide as striae, sulmarginal crenulations as in aculeatus but smaller, rows of discal crenulations or tubercles absent, punctures obscured by vestiture. Declivity convex, rather steep; interstriae 2 impressed but convex, 1 slightly elevated, 3 and 9 not noticeably elevated, tubercles not evident. Vestiture consisting of moderately large, strongly keeled (tripartite) scales in three irregular ranks except uniseriate on declivital interstriae 2 , each scale slightly longer than wide; median row on each interstriae distinctly longer than ground cover; color black except small white patches on interstriae 1 and 2 just behind scutellum, on 6 at similar level, on 2 to 5 and 7 at base of declivity, and on apex of 9 .

Female.-Similar to male except frons planoconvex, upper three-fourths bearing a rather strongly elevated median carina; fewer elytral scales keeled in ground cover.

Distribution.- Pennsylvania and New Jersey to Missouri.

USA: Distriet of Columbia: Washington, V-29. Mis. souri: Jefferson City, V-17. New Jersey: Clemton, $\mathfrak{V} 20$. Pennsylvania: Harrisburg, 1923, Ash, Champlain. West Virginia: Kanawha Station, Fraxinus, A. D. Hopkins: Wood Co., 14-VII-08, A. D. Hopkins.

Host.- Fraxinus americana.
Brology.- Evidently similar to aculeatus.
Notes. - The above descriptions were based on the holotype and on 187 other specimens.

## 6. Hylesinus mexicanus (Wood)

Leperisinus mexicanus Wood, 1956, Camadian Ent. 88:249 (Holotype, male; Tecamachalco. Puebla. Mexico; Snow Ent. Coll. Univ. Kansas)
Diagnosis.- This species is distinguished from fasciatus LeConte by characters summarized in the above key. In addition, the female frontal carina is less strongly elevated. and most specimens have the light colored scales in the declivital ground vestiture tinted yellow.

Male.- Length 2.3-2.9 mm, 1.8 times as long as wide; color almost black, with patches of black, white, and yellowish tan scales.

Frons as in fasciatus except setae slightly longer.

Pronotum as in fasciatus except patches of white scales larger, also a patch of white scales just behind anterior margin.

Elytra as in fasciatus except monseriate rows of fine, interstrial tubercles present on basal half of disc; erect, uniseriate, median row of scales longer on dise and on declivity almost twice as long as ground vestiture, pale erect scales white in color, pale ground cover scales at least on declivity usually yellowish $\tan$ (in some specimens these also entirely white). Pale scales on basal half of elytra and at base of declivity forming almost continuous, transverse bands of white color, posterior one continued in lateral area to apex and sometimes joining anterior band (color pattern highly variable); pale scales usually comprise at least half of total number.

Female.-Similar to male except frons planoconvex, with a conspicuous median carina, upper half of carina less strongly elevated than in fasciatus: only longer, erect, interstrial scales strongly keeled.

Distribution:- Durango and SW Texas to Puebla.

USI: Texas: Big Bend N. P. in Pulliam Canyon, 17-V' 59.2500 m . I1. Howden; Rivers, $27-\mathrm{V} \mathrm{J}-38$, R. I. Sailer Waco, 2-XI-39, P. A. Cliek. MEXICO: Aguascalientes: Aguascalientes, 12-VI-65, 2100 m, No. 42. S. L. Wood. Durango: Quencame, 23-IV-77. "palo blanco." M. M. Furniss; San Juan del Rio, 25-V1I-53, $1800 \mathrm{~m}, \mathrm{~S}$. L. Wood. Puebla: Tecamachalco, 2-VII-53, S. L. Wood.

Host. - A small desert tree (Oleaceac).
Biology. - The habits apparently are essentially as in aculeatus.

Notes. - The above treatment was based on the holotype and on 56 other specimens.

The specimens from Three Rivers, Texas, and the one from San Juan del Río, Durango, were previously referred by me (Wood 1956:248) to fasciatus. It is now recognized that they are small representatives of mexicamus, with a higher percentage of black scales than is normal for this species.

## 7. Hylesinus aztecus Wood

Hylesimus aztecus Wooel, 1950, Great Basin Nat. 40:354
(Holotype, male; Chapingo, Mexico. Mexico: Wood Coll.)

Diagnosis.- This species is distinguished from californicus (Swaine) by the larger size, by the presence of a fine, low, median frontal carina in both sexes, by the less strongly concave male frons and less strongly convex female frons, and by differences in the declivital interstrial setae described below.

Male.- Length 3.8-4.2 mm, 1.8 times as long as wide; vestiture of dark brown and tan scales in a pattern similar to californicus.

Frons similar to californicus except very shallowly concave from epistoma to upper level of eyes, a low, median carina on lower half, and granules on upper areas of head conspicuously larger.

Pronotum similar to californicus except asperities smaller, punctures smaller, less definite, and scales averaging much more slender.

Elytra similar to californicus except interstrial crenulations more numerous, smaller, confused (a median row not predominating); declivital interstriae 1 less strongly elevated, 2 wider; ground setae on declivital interstriae 2 in two indefinite ranks (never uniseriate); erect setae always absent on 2, present on 1 and 3 , each four to eight times as long as wide, spaced within a row by distances greater (one to four times) than length of a seta.

Female.- Similar to male except frons less strongly, more broadly impressed (irregularly flattened); declivital interstriae 1 less strongly elevated (vestiture not clearly sexually dimorphic).

Distribution.- Mexico.
MEXICO. Mexico: Chapingo, 12-XII-1978, Fraxinus uhdei. T. H. Atkinson.

Biology.- The habits apparently are as in aculeatus.

Notes.- The above treatment was based on the type series of 14 specimens.

## 8. Hylesinus californicus (Swaine) Fig. 47

Leperisimus californicus Swane, 1916, Canadian Ent. 48:190 (Ilolotype female; San Diego. California: Canadian Nat. Coll., 9249)
Leperisimus hoferi Blackman, 1943, Proc. U.S. Nat. Mus. 94:394 (Holotype, female; Salsino Canyon, Arizona; U.S. Nat. Mus., 56573); Wood, 1971, Great Basin Nat. 3I:147. Synonymy
Leperisinus californicus Essig, 1957, Insects and Mites of Western North Imeriea, p. 519. Nomen nudum
Diagnosis. - This is the most common and most widely distributed representative of the
genus in western North America. This species and guatemalensis Wood have long, hairlike, erect, bristles on discal interstriae 8 to 10 , a larger patch of hairlike setae near the basal
margins of the elytra, flattened and impressed interstriae 2 (at least in the male), and the longer, erect interstrial scales on the declivity that indicate a close relationship to

Fig. 47. Hylesinus californicus: Adult. dorsal aspect, and galleries. (After Swaine 1916.pl. 8.)
one another. This species is distinguished from guatemalensis by characters summarized in the above key, and by the whitish $\tan$ color of the pale scales.

Male.- Length $2.0-3.1 \mathrm{~mm}, 1.95$ times as long as wide; color dark brown, with color pattern formed by dark brown and light tan scales.

Frons concavely impressed on a triangular area from epistomal margin to upper level of eyes; epistomal margin feebly, narrowly elevated, broadly, shallowly emarginate; surface reticulate, finely, rather closely, obscurely punctured except at center of concavity; vestiture rather fine, moderately long, abundant.

Pronotum 0.71 times as long as wide; widest at base, sides arcuately converging to narrow constriction just behind very broadly rounded anterior margin; surface reticulate, punctures large but obscure, on middle third their anterior margins finely asperate, lateral areas each bearing about a dozen and a half coarse asperities, with submarginal row obsolete on median half of anterior margin; scales large, broad in pale areas, in dark areas similar scales supplemented by dark, slender bristles.

Elytra 1.3 times as long as wide, 2.1 times as long as pronotum; sides slightly wider near base, almost straight, converging slightly posteriorly on slightly less than basal two-thirds, rather narrowly rounded behind; anterior margins each armed by about 13 crenulations; striae slightly impressed, punctures moderately large, deep; interstriae slightly less than twice as wide as striae, each with a uniseriate row of narrow crenulations, crenulations increased in number at base, confused, particularly on 2 and 3. Declivity convex, moderately steep; striae not impressed, punctures somewhat reduced; interstriae 1 moderately, 3 and 9 feebly elevated, 2 flat, rather strongly impressed. Vestiture largely of rather large, pubescent or subplumose scales in about three ranks on each interstriae, part of median rank longer, erect; erect setae slender, almost hairlike toward base, becoming scalelike on 1 one-third from base, at margin of declivity on 3 and 4 , below middle of declivity on 5; each erect seta at least twice as long as ground seales, much longer on sides; none of scales keeled.

Female.- Similar to male except frons convex on upper two-thirds, a large, short, subtuberculate carina on lower half, above epistoma; epistomal margin not emarginate; erect interstrial scales shorter, less than twice as long as ground scales.

Distribution.- Oregon and North Dakota to Chihuahua and Texas.

USA: Arizona: Chiricahua Mts., Glendale, Huachuca Mts.. Miller Canyon in Huachuca Mts., Oak Creek Canyon, Patagonia, Phoenix, Sabino Canyon, Tucson. Tubao. California: Grass Valley, Inyo Co., Mare Island, Merced, Mission Valley in San Diego Co., Palo Alto, San Diego. Colorado: Greeley. New Mexico: Meek. North Dakota: Bottineau Co. Oklahoma: Holdenville. Oregon: Eugene, Forest Grove, Junction City, McMinnville, Portland, Salem. Texas: Brownsville, Cameron Co., Ft. Davis, Hidalgo Co. Utah: Moab, Provo, Vernal. MExICO: Chihuahua: Colonia Juárez.

Hosts.- Fraxinus americana, F. latifolia, $F$. pennsylvanica, F. velutina, and Olea europeac.

Biology.- Evidently indistinguishable from aculeatus.

Notes.- The above descriptions were based on the holotypes of californicus and hoferi and on 242 other specimens.

Blackman evidently was unfamiliar with the full distribution of this species and based his hoferi on minor characters that vary within series. Examination of his type series leaves no doubt that this is a synonym of Swaine's species. Through an error in citing californicus the author name was changed from Swaine to a new species designation in the 1957 revision of Essig's book, resulting in a name for which a description was not given or a type specimen designated.

## 9. Hylesinus guatemalensis (Wood)

Leperisinus guatemalensis Wood, 1967. Great Basin Nat 27:89 (Holotype, female; Volcan Pacaya, Esquintla, Guatemala; Wood Coll.)
Diagnosis.- This species is very closely allied to californicus (Swaine), but it may be distinguished by characters summarized in the above key, by the yellow-orange tint of the pale scales, by the more broadty convex upper half of the male frons, and by the nearly complete submarginal row of asperities on the anterior margin of the pronotum.

Male.- Length $2.4-3.1 \mathrm{~mm}, 1.8$ times as long as wide; color dark brown, with color
pattern formed by dark brown and light yellowish tan scales.

Frons broadly concave from epistoma to upper level of eyes; epistomal margin feebly elevated and broadly, very shallowly emarginate; surface reticulate, punctures fine, obscure; vestiture fine, rather short, rather sparse.

Pronotum as in californicus except submarginal row of asperities almost complete to median line, and slender setae in median, dark area obsolete; dark scales arranged in a large median and two smaller lateral diamond patterns, median one reaching both anterior and posterior margins.

Elytra as in californicus except scales smaller, each about one-fourth as wide as an interstriae, and slender, erect bristles replaced on interstriae 1 to 4 by erect scales, slender bristles on bases of 5 and 6 and more extensively on 7 to 10 ; pale scales with a distinct yellow-orange tint.

Female.- Similar to male except frons convex above, flattened on lower half, entirely devoid of a carina or tubercle, epistoma not at all emarginate; erect interstrial setae shorter, but at least twice as long as ground scales.
Distribution.- Guatemala.
gUatemala: Volcán Pacaya, 1-VI-64, 1300 m , No. 661, S. L. Wood. From three host tree species, none of which resembled Fraxinus.

Biology.- Evidently very similar to aculeatus.

Notes.- The above treatment was based on the type series of 92 specimens.

## Genus ALNIPHAGUS Swaine

Alniphagus Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. BuIl. 14(2):73 (Type-species: Hylesinus aspericollis LeConte, monobasic)
Hylastinoides Spessivetsev, 1919. Ent. Mon. Mag. 55:249 (Type-species: Hylastes alni Niisima); Swaine, 1919, Rept. Canadian Arc. Exp. 3E:279. Synonymy

Diagnosis.-From American Hylesinini this genus is distinguished by the elongate antennal scape, by the 7 -segmented funicle, by moderately flattened, very slightly asymmetrical antennal club with three sutures, the first of which is partly septate, by the armed anterolateral areas of the pronotum, by the shallowly emarginate eve, by the widely separated anterior coxae, and by the broad, emarginate third tarsal segments.

Description.-Length 2.1-3.4 mm, 2.0-2.1 times as long as wide. Frons very slightly dimorphic, male frons weakly impressed, female more strongly convex. Eye elongate, shallowly emarginate; finely granulate. Antennal scape elongate, attaining posterior margin of eye; funicle 7 -segmented; club moderately flattened, very slightly asymmetrical, marked by three sutures, first partly septate. Pronotum wider than long, anterolateral angles armed by several asperities. Scutellum small, depressed. Elytral bases armed by a long row of overlapping crenulations; declivity convex, rather steep, conservatively sculptured, costal margins not ascending behind. Vestiture hairlike.

Distribution.- Western North America and Japan; three species are known; two are from western North America and one is from Japan. Two species recently added to this genus by Schedl (1963:259) appear to be incorrectly placed.

Biology.- These monogamous species attack the lower bole of alder trees, where they construct unbranched, uniramous, more or less longitudinal egg galleries in the phloem tissues. The larval mines wander in the general direction away from the parental tunnel and may cross one another repeatedly. According to Chamberlin (1958:100) the female constructs the entrance tumnel and is later joined by a male. Two generations per year evidently are normal. Special hibernation tunnels are constructed in the outer bark to pass the winter.

## Key to the Species of Alniphagus

1. Declivital ground vestiture very short, scalelike, much shorter than on disc; serrations of interstriae 9 and 10 , as seen from dorsal aspect, form an almost continuous sawlike lateral profile from base to apex of elytra; larger, darker, with shorter, less abundant pubescence and larger, more numerous interstrial cremulations and tubercles; Alaska to Califormia and Utah; 2.6-3.4 mm

- Crenulations on discal interstriae much smaller, less abundant; ground vestiture on declivity stout, elongate, as on disc; serrations of interstriae 9 and 10 usually visible from dorsal aspect only at base and in declivital area; smaller, lighter in color, with slightly longer, more abundant pubescence and much smaller, less numerous discal crenulations and declivital tubercles; British Columbia to California; 2.1-2.8 mm

2. hirsutus Schedl

## 1. Alniphagus aspericollis (LeConte) Figs. 48, 96

Hylesinus aspericollis LeConte, 1876, Proc. Amer. Philos. Soc. 15:380 (Lectotype, male; California, evidently Santa Barbara; Mus. Comp. Zool., 975. present designation)
Alniphagus aspericollis: Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):73.
Diagnosis. - In addition to the characters summarized in the above key, this species is more slender and has very slightly shorter elytral setae than hirsutus Schedl.

Male.- Length $2.6-3.4 \mathrm{~mm}, 2.1$ times as long as wide; color dark brown, elytra usually slightly lighter.

Frons convex, median area on lower twothirds weakly impressed, a narrow, transverse impression just above epistoma; surface mostly reticulate, shining, punctures moderately coarse, very shallow, close; vestiture of sparse, fine, rather short, inconspicuous hair.

Pronotum 0.79 times as long as wide; widest a fourth of length from base, sides moderately arcuate from base, converging slightly, very broadly rounded, almost subemarginate in front; surface smooth and shining with very close, moderately deep punctures of irregular, small to moderately large size, somewhat reticulate anteriorly; anterolateral angles armed by one to three coarse asperities, several smaller asperities scattered in anterolateral areas, including median area near anterior margin; vestiture of stout, hairlike setae, each about equal in length to diameter of largest punctures.

Elytra 1.55 times as long as wide, 2.2 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; basal margins each armed by 13 low crenulations; striae weakly impressed, punctures rather coarse, decp; interstriae wider than striae, each armed by a somewhat uniseriate row of coarse crenulations, most at least half as wide as interstriae, supplemental fine punctures rather obscure. Declivity convex, steep; interstriae $1,3,5,7$, and 9 moderately elevated, 1 and 3 each
armed on upper two-thirds by six to eight pointed tubercles. Vestiture of stout, recumbent, interstrial hair on disc equal in length to diameter of a strial puncture, shorter, scalelike on declivity, and erect rows of sparse, interstrial, hairlike setae, each onethird as long as distance between rows.

Female.- Similar to male except frons more nearly convex; lateral asperities on pronotum evidently very slightly larger; declivital tubercles extend to apex.

Distribution.- Alaska to California and Utah.

Alaska: Hollis. CANADA: British Columbia: Agassiz, Barkerville, Bowser, Boyston, Cowichan, Goldstream, Haspencolls on Goat River, Massett on Queen Charlotte Islands, Metlakatla, Pender Harbor, Terrace, Vaseaux, Victoria. USA: California: Bass Lake, Eureka, Fieldbrook. Hat Creek, Haviah, Marin Co.. Mt. Tamalpais, Placer R. S. in Madera Co., Placerville, Scotia, Taylorville, Ventura, Yosemite N. P. Idaho: Deary, Kassel. Oregon: Astoria. Colestein, Corvallis, Dever, Forest Grove, Gardner, Gold Lake in Willamette N. F., Hood River, Newport, Neil Creek, Otis, Portland, Santiam N. F. Utah: American Fork Canyon. Washington: De Moines, Hoquiam, Miller Lake, Puyallup, Quinault, Seattle.

Hosts.-Alnus rhombifolia, A. rubra, and A. tenuifolia.

Biology.-As described for the genus.
Notes.- The above descriptions were based on LeConte's syntypes and on 310 other specimens.
lnasmuch as a type has not been designated from the five syntypes in the LeConte collection, I here designate the first specimen, a male, as the lectotype for the species as cited above.

## 2. Alniphagus hirsutus Schedl Figs. 49-50

Alniphagus hirsutus Schedl. 1949, Canadian Ent. 81:236 (Ilolotype, male; Copper Mountain, British Columbia; Schedl Coll.)
Diagnosis. - This species is very closely related to aspericollis (LeConte) but can be distinguished, with difficulty, by the characters summarized in the above key, by the
stouter body, and by the slightly longer elytral setae.
Male.- Length 2.1-2.8 mm, 2.0 times as long as wide; color of pronotum reddish brown, elytra usually somewhat yellowish brown.

Frons as in aspericollis.
Pronotum 0.75 times as long as wide; as in aspericollis except sides more strongly arcuate; punctures less definite but more uniform in size, vestiture longer, each seta more than twice as long as diameter of a large puncture.

Elytra 1.40 times as long as wide, 2.1 times as long as pronotum; outline as in aspericollis, but stouter; basal margins each armed by 11 crenulations; striae feebly impressed, punctures large, rather indistinctly impressed; interstriae wider than striae, each armed by fine, low crenulations, each usually less than

Fig. 48. Alniphagus aspericollis: Dorsal aspect. (After Bright 1976:207.)
one-third as wide as interstriae, supplemented by moderately large punctures. Declivity as in aspericollis except alternate interstriae less strongly elevated, tubercles much smaller, less than four on each interstriae. Vestiture with ground vestiture slightly longer, not scalelike on lower declivity, erect setae longer, at least half as long as distance between rows.

Female.-Similar to male except frons more nearly convex; pronotal asperities larger.
Distribution. - British Columbia to California.

CANADA: British Columbia: Copper Mountain, 22-V-29, Alnus sitchensis, G. S. Smith; Lorna, 21-VI-25. 17202 lot 3556, Pimus contorta error, beating record only): 7 miles N Oliver, 18-V-58. H. Howden. USA: California: Cliff Lake, Siskiyou Co., $28-\mathrm{VII}-39$. Alnus tenuifolia, W. D. Bedard. Oregon: Corvallis, 1-VIII-39. Aluus. J. Schuh; Gold Lake, Willamette N. F., 16-V1-61, Aluus temuifolia and A. sinuata, S. L. Wood.

Hosts.- Alnus sinuata and A. tenuifolia.
Biology. - Essentially as in aspericollis as mentioned for the genus.

Notes.- The above descriptions were based on the holotype and on 45 other specimens.

## Genus PHLOEOBORUS Erichson

Phlocoborus Erichson, 1836. Archiv Naturgesch. 2(1):54 (Type-species: Phloooborus rudis Erichson, sul)sequent designation by Hopkins. 1914. Proc. U.S. Nat. Mus. 48:126)
Phloootrupes Erichson, I836, Archiv Naturgesch. 2(1):53 (Type-species: Phloeotrupes grandis Erichson. subsequent designation by Hopkins 1914, Proc. U.S. Nat. Mus. 48:127): W'ood. 1978, Great Basin Nat. 38:383. Synonymy
Diagnosis.- This genus is not closely allied to any other in the American fauna. It is distinguished by the very large size, by the stout body form, by the entire eye, by the 7 segmented antennal funicle and distinctive club, by the near absence of crenulations on the basal margins of the elytra, by the widely separated front coxae, and by the presence of a large propleural fovea in the female.

Description.-Length $4.6-13.0 \mathrm{~mm}$, 1.6-1.9 times as long as wide; color dark brown to black. Frons at least partly concave in male, convex in female, usually with a median carina below; eyes large, entire, varying from widely separated to contiguous above. Antennal scape elongate, funicle 7 -

Figs. 49-50. Alniphagus hirsutus: 49, Antenna, 50A, male head; B, female head.
segmented; club ovate, moderately, symmetrically compressed, with two straight sutures, minutely, rather densely pubescent. Pronotum wider than long, with or without asperities. Scutellum visible, small. Crenulations on elytral bases poorly developed to absent; striae impressed, punctures usually small; interstriae usually crenulate; declivity convex, conservatively sculptured. Vestiture almost obsolete; minute hair visible on some species. Anterior coxae rather widely separated; third tarsal segments broad, pubescent. Propleura with a large fovea on anterior half, often ornamented with hairlike setae.

Distribution.- Southern Mexico to Argentina; about a dozen valid species are known; five of them oceur in Mexico and Central America.

Brology.- The species of this genus are occasionally attracted to light. They breed in moist or wet tropical forests in cut or broken limbs or logs larger than 20 cm in diameter. The male bores on the underside of the log directly, deeply into the wood on a radial plane, forming an unbranched tunnel with a turning niche near the entrance. The female then extends the tumnel, frequently adding one or more branches. The eggs are deposited and packed individually in niches that are randomly distributed on all sides of the
tunnel. The larvae form long, wandering mines through the wood. Pupation occurs rather deep in the wood near the end of the one-year life cycle. The adult flight period evidently is confined to the latter part of the dry season. Apparently fungi are associated with the beetles and cause a rapid decay of the wood near the tunnels; pupal cells usually are lined by the spore-forming hyphae. Apparently the fungus is not used as food directly; it evidently modifies the hard wood, thereby increasing the nutritional value of those tissues.

Notes.- Until recently Phloeotrupes Erichson was recognized as a separate genus. However, the characters of the tibiae, antemnae, and palpi on which the separation was made vary to such an extent that no combination of characters will separate the two. Although the name Phloeotrupes has page priority, I exercised the option of the first revisor, above, and selected Phloeoborus because it applies to a larger group of species and is more widely known.

The nomenclature of species in this genus is in chaos. The individual variability, sexual dimorphism, and unavailability of adequate series have resulted in the description of numerous synonyms. A thorough revision of the group is needed.

Key to the Species of Phloeoborus

1. Male frons deeply excavated to slightly impressed above upper level of eyes; eyes separated by about twice width of an eye; body stout, 1.6 times as long as wide; sculpture of pronotum irregular, anterolateral angles elevated and each armed by three basally contiguous, coarse asperities, a row of smaller, marginal and one of submarginal asperities more strongly elevated than numerous low
asperities covering anterior half of pronotum; antennal club with suture 1 subangulate (at least in male); Veracruz to Brazil; 5.6-9.0 mm ....... 1. asper Erichson

- Male frons shallowly excavated on lower half, never approaching upper level of eyes; body usually more slender; pronotal asperities, when present, of more or less uniform size (except some males of scaber armed on anterolateral angles); sutures of antennal club, when visible, straight; spacing of eyes variable
2(1). Eyes separated by almost three times width of an eye; body stout, 1.6 times as long as wide; declivital interstriae 2 unarmed, crenulations on all interstriae rather sparse; female pronotum smooth, punctured, male finely asperate on anterior half; Mexico (Veracruz?) to Brazil; 4.6-8.1 mm

2. punctatorugosus Chapuis

- Eyes narrowly separated by a distance equal to less than width of an eye; declivital crenulations more abundant, continuing on all interstriae to declivital apex (except on 2 in belti); body usually more slender 3
3(2). Declivital interstriae 1 and 3 convex and tuberculate, 2 impressed and unarmed; Nicaragua; 7.6 mm 3. belti Blandford
- Declivital interstriae 2 not impressed, armed by tubercles as on 1 and 3 .................... 4

4(3). Strial punctures very small, their diameters about one-fifth width of an interstriae; surfaces dull, deeply reticulate on pronotum and elytra; finely asperate on anterior three-fourths of pronotum; Veracruz to Brazil; 6.3-9.5
4. scaber Erichson

- Strial punctures larger, their diameters one-third width of an interstriae; surface shining, smooth on pronotum, superficially reticulate on parts of elytra; pronotal asperities restricted to lateral areas on anterior half, often obscure; Guatemala to Brazil; $7.5-11.7 \mathrm{~mm}$

5. rudis Erichson

## 1. Phloeoborus asper Erichson

Phloeoborus asper Erichson, 1836, Archiv Naturgescl. 2(1):55 (Holotype, male; Brazil; Zool. Mus. Berlin)
Phlocoborus imbricornis Eichhoff, 1868, Berliner Ent. Zeitschr. 12:148 (Holotype, male; Mexico; presumably lost with Hamburg Mus.); Chapuis, 1869, Synopsis des Scolytides, p. 8. Synonymy
Phloooborus otatus Chapuis, 1869, Synopsis des Scolytides, p. 15 (Lectotype, male; Cayenne; Brussels Mus., present designation); Wood. 1973, Great Basin Nat. 33:180. Synonymy
Phloeoborus rugatus Blandford, 1897, Biol. Centr. Amer., Coleop. 4(6):153 (Lectotype, female; Chontales, Nicaragua: British Mus. Nat. Hist., present designation); Wood, 1973, Great Basin Nat. 33:180. Synonymy
Diagnosis. - This species is unique among Central American Phloeoborus. It may be distinguished from other species in the area by the male frontal concavity that extends above the upper level of the eyes, by the widely separated eyes, by the prominent elevated asperities on the anterolateral angles of the pronotum, and by the subangulate, glabrous,
basal, pseudosegment of the antennal club (evidently a male character).

Male.- Length $5.6-9.0 \mathrm{~mm}, 1.6$ times as long as wide; color almost black.

Frons concave from epistomal margin to above upper level of eves, much wider on lower third, lower half bearing an acute, rather high median carina, lateral margins subacute, upper two-thirds not continuous with lower third; surface reticulate, a few fine punctures and stout setae on lateral areas; eyes separated above by twice width of an eye.

Pronotum 0.73 times as long as wide; widest at base, sides arcuately convergent to anterolateral angles, median two-thirds very broadly rounded; anterior half or more finely asperate to subasperate, with anterolateral angles elevated and each armed by three basally contiguous, coarse asperities, anterior margin armed on median half by a row of basally contiguous asperities, a similar transverse row of asperities one-fourth pronotum
length from anterior margin; posterior fourth grading from subasperate to punctate; areas between asperities and within punctures very minutely reticulate-granulate. Vestiture sparse, largely limited to marginal areas, consisting of short, stout bristles.

Elytra 1.07 times as long as wide, 1.9 times as long as pronotum; widest one-third from base, sides weakly arcuate and almost parallel on less than basal half, then arcuately convergent to broadly rounded posterior margin; scutellum set in a V-shaped notch three times as wide as scutellum; basal margins abruptly precipitous, marginal crenulations poorly formed, largely indefinite; striae very narrowly, deeply impressed, punctures very small, obscure; interstriae about four times as wide as striae, minutely reticulate-granulate, armed by abundant, closely set, confused, transverse crenulations, each crenulation subacute, usually narrower than half width of an interstriae. Declivity steep, convex, confined to posterior third; strial puncture slightly larger and more distinct than on disc; sutural interstriae weakly elevated, on left side strongly narrowed; crenulations on all interstriae uniseriate, low, decreasing in size posteriorly, obsolete on lower third; interstriae 9 strongly, acutely elevated on sides behind junction with 10 , weakly convex on posterior half of declivity. Vestiture consisting of very short, stout, recumbent hair, each shorter than distance equal to an adjacent strial puncture.

Female.- Similar to male except frons convex and eves more broadly spaced.

Distribution.- Veracruz to Brazil.
NEXICO: Veracruz: Lago Catemaeo, 1-3-V-69, D. E. Bright: Santecomapan, 10-V1-69, II. Howden. Chiapas Palenque Rums, 22-VI-69, D. E. Bright. NICARAGUA: Chontales. OTIIER COUNTRIES: Brazil. British Guiana, Trinidad, Venezuela

Biology. - The hosts and habits have never been recorded.

Notes. - The above description was based on the male holotype of asper, on the male holotype of imbricomis, on the male syntypes of ovatus, on the female syntypes of rugatus, and on 35 other specimens.

Of the three Chapuis male syntypes of ovatus the first is here designated as the lectotype of ovatus Chapuis; of the two female syntypes of rugatus Blandford the Chontales
specimen now in the British Museum (Natural History) is here designated as the lectotype of rugatus Blandford, as cited above.

## 2. Phloeoborus punctatorugosus Chapuis

 Fig. 51Phloeoborus punctatorugosus Chapuis, 1869, Synopsis des Scolytides, p. 14 (Holotype, male; Nouvelle Grenade; Mus. Roy. Nat. Belge)
Phloeoborus breviusculus Chapuis, 1869, Synopsis des Scolytides, p. It (Holotype, male; Cayenne; Mus. Roy. Nat. Belge); Wood, 1977, Great Basin Nat. 37:208. Synonymy
Phloeoborus nitidicollis Chapuis, 1869, Synopsis des Scolytides, p. 14 (Lectotype, female; Nova Fribourg, Rióo de Janeiro, Brazil; Brussels Mus., present designation); Eggers, 1942, Arb. Morph. Taxon. Ent. Berlin-Dahlem 9:267. Synonymy
Diagnosis.- The widely separated eyes, the stout body form, the very sparsely

Fig. 51. Phlocoborus punctatorugosus: Male, dorsal aspect.
crenulate interstrial asperities, and the sexually dimorphic pronotum distinguishes this species from other Central American representatives of the genus.

Male.- Length 4.6-8.1 mm, 1.6 times as long as wide; color very dark brown, almost black.

Frons convex above, a rather shallow, triangular, concave impression extending from epistomal margin about three-fourths of distance to upper level of eyes; a weak median carina in impressed area; surface minutely reticulate, dull; area below upper level of eyes except in concavity bearing low, isolated, transverse tubercles; vestiture restricted to concavity, of minute hair, longer toward epistoma.

Pronotum 0.68 times as long as wide; widest at base, sides feebly arcuate, converging on posterior four-fifths, then abruptly narrowed to very broadly rounded anterior margin; surface minutely reticulate, dull, anterior two-fifths rather finely asperate, anterolateral angles unarmed; posterior two-fifths with sparse, shallow, somewhat reniform punctures. Glabrous.

Elytra 1.1 times as long as wide; sides almost straight and parallel on basal half, rather broadly rounded behind; scutellar notch not wider or deeper than scutellum; basal margins abrupt, feebly elevated, crenulations not distinguishable; striae very narrowly, moderately impressed, punctures very small distinct; interstriae at least four times as wide as striae, minutely reticulate, dull, with minute, sparse, indistinct punctures and sparse, low, rounded crenulations, fewer than a dozen crenulations on each interstriae. Declivity steep, convex, confined to slightly more than posterior third; strial punctures very slightly larger and deeper than on disc; interstriae 1 weakly elevated, 1 and 3 with two or three fine, low crenulations near upper margin, minute punctures uniseriate except moderately confused on 1 and 3 ; interstriae 9 narrowly, strongly elevated from junction with 10 to middle of declivity, weakly convex behind. Glabrous.

Female.-Similar to male except frons convex, subshining, rather coarsely, shallowly, closely punctured, tubercles entirely absent; pronotal reticulaion almost obsolete, shining, entire surface sparsely, finely, rather
deeply punctured, asperities entirely absent; small, subacute interstrial crenulations on elytral dise much more abundant, often exceeding three dozen.

Distribution.- Southern Mexico to Brazil.

MEXICO: Presmmably Veracruz. COSTA RICA: San José, San José, 22-X-6:3, 1300 m , Psidium ǵataca. S. L. Wood; Turrialla, 9-III-64, 700 m , at light, S. L. Wood, 20-X-53, Coffca arabica.

Hosts.-Coffea arbica, Lecythis costaricensis, Psidium guajaza; also from Inga in Colombia.

Biology.- Adult beetles entered on the under side of large guava logs in shady places in a coffee plantation. They bored through the bark into sound wood on the underside of the log, where they introduced fungal growth that caused a very rapid white rot. The adult tunnels formed no definite pattern, hut wandered and branched at random. Egg niches were formed along growth rings, either in rings around the tunnel if it cut across the grain, or in rows along the sides if the tunnel paralleled the grain. The old egg tunnels were all stained black. The larvae made very long, winding tunnels through the decaying wood. Both larvae and young adults in their pupal cells were inactive during the climax of the Costa Rican rainy season in November. The age of the tumnels and inactivity of the brood suggested only one generation per year. Some decayed logs that could be crumbled by hand still contained a few living young adults.

Notes.- The above descriptions were based on the holotypes of punctatorugosus and breviusculus and on 62 other specimens. Three female syntypes of nitidicollis were examined and the first of these in the Brussels Museum is here designated as the lectotype of nitidicollis Chapuis as cited above; however, I am not entirely convinced that Chapuis' Brazilian species is the same as punctatorugosus that occurs from Veracruz to Colombia.

## 3. Phlocoborus belti Blandford

Phloeoborus belti Blandford. 1897. Biol. Centr. Amer., Coleopt. 4(6):151 (IIolotype. female: Chontales. Nicaragua; British Mus. Nat. Hist.)
Diagnosis.- This species is distinguished from rudis Erichson by the reticulate vertex region of the head, by the more deeply
subcrenulately punctured pronotum, by the smaller strial punctures, by the higher interstrial crenulations, and by the impressed, unarmed declivital interstriae 2 .

Female.- Length $7.6 \mathrm{~mm}, 1.7$ times as long as wide; color dark reddish brown. Frons as in scaber Erichson.

Pronotum as in rudis except punctures deeper, surface in lateral and basal areas irregular, subcrenulate, with a few irregular short, confluent grooves near base; surface almost smooth, a very obscure reticulation indicated on both interspaces and punctures.

Elytra 1.2 times as long as wide; interstriae rather deeply impressed, punctures small, mostly distinct; interstriae obscurely reticulate, rather strongly convex, about three to four times as wide as striae, crenulations high, not more than half as wide as an interstriae, umiseriate on posterior half of 1,2 , and 4 , staggered to confused on all of 3 and on basal half of 2 and 4 . Declivity broadly convex, rather steep, more strongly reticulate; interstriae 2 flat, unarmed, rather narrow, 1 convex, with a row of narrow tubercles decreasing slightly in size toward apex, 3 similar to 1 except tubercles slightly larger, apex of 5 joins 3; lateral areas as in rudis.

Distribution.- Nicaragua.
NICARAGUA: Chontales, T. Belt.
Notes.- The above treatment was based on the holotype.

## 4. Phlocoborus scaber Erichson

Phloeoborus scaber Erichson, 1836, Archiv Naturgesch. 2(1):55 (Lectotype, female; Bahia, Brazil; Berlin Mus., present designation)
Phocotrupes caclatus Blanchard, 1846, In Brulle, Insectes de I'Amerique Meridiconale recneillis par Alcide dOrbigny 2:204 (Syntypes; Bolivia; Paris Mus.); Eggers, 1933, Ent. Nachrbl. 7:17. Synonymy
Phlocohorus sericeus Chapuis, 1869, Synopsis des Scolytides, p. 13 (Lectotype, male; Cayemne; Brnssels Mus., present (lesignation); Eggers, 1942, Arh. Morph. Taxon. Ent. Berlin-1)ablem 9:267. Synonymy
Phlocoborus opacithorax Schedl, 1940, Arb. Morph. Taxon. Ent. Berlin-Dahlem 7:20) (Syntypes, female; Panzos, Guatemala; Instit. Pflanzenschutzforschung Kleinmachnow); Wood, 1974, Great Basin Nat. 34:285. Synonymy
Diagnosis.- The rather narrowly separated eyes, the finely asperate pronotum, the coarsely crenulate elytra with the entire
surface reticulate-granulate, the declivital sculpture, and the sculpture of the male frons distinguish this species from other Central American representatives of the genus.

Male.- Length 6.4-7.5 mm, 1.7 timés as long as wide; color dark reddish brown.

Frons broadly, deeply impressed on lower two-thirds of area below eyes, this area with an acute median carina to epistomal margin; a very slight median impression continuing to upper level of eyes, convex above eyes; surface reticulate, rather coarsely punctured except impressed area obscurely punctured; vestiture of sparse, short, stout, yellow bristles in impressed area. Eyes elongate, separated above and below by about one-half to three fourths width of an eye. Scape reaching middle of eye.

Pronotum 0.68 times as long as wide; widest about middle, sides moderately arcuate, basal and anterior margins about equally, very broadly rounded; anterolateral angles rather coarsely asperate, asperities gradually decreasing in size posteriorly on anterior two-thirds, then coarsely, closely, subasperately punctured to base; surface reticulate except apices of asperities; vestiture consisting of sparse, very short, stout bristles.

Elytra 1.2 times as long as wide, 2.1 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; basal margins abruptly precipitous, marginal crenulations indefinite, scutellar notch very shallow, indistinct; striae rather strongly impressed, punctures small, distinct; interstriae convex, at least five times as wide as striae, crenulations coarse, close, usually confused, each about one-fourth to two-thirds as wide as interstriae. Declivity convex, steep; strial punctures deeper than on dise; crenulations less than one-fifth as wide as interstriae, becoming uniseriate and decreasing in size until often obsolete on lower third. Vestiture consisting of minute, stout bristles, their length usually not exceeding diameter of a strial puncture.

Female. - Similar to male except larger, $7.5-9.5 \mathrm{~mm}, 1.8$ times as long as wide; frons convex, with a slight, transverse impression above epistoma, carina present; pronotal asperities higher and more acute; anterior half of propleura bearing a large, hemispherical
cavity with a marginal fringe of long, yellow hair.

Distribution.- Veracruz to Brazil.
MEXICO: Veracruz: Orizaba, Salle; Cordoba, Salle and Höge; Santecomapan, 10-VI-69, H. Howden. GUATEMALA: Pantaleon, Champion. BRITISH HONDURAS: Stan Creek District in Middlesex, 7-V-63, E. C. Welling. NICARAGUA: Chontales, Janson. COSTA RICA: Tilarán, Guanacaste, VII-66, leguminous log, J. B. Karren. PANAMA: Barro Colorado I land, Canal Zone, 15-II-64, L. J. Bottomer; Bugaba and Volcán de Chiriquí, Champion. OTHER COUNTRIES: Brazil, Colombia, Jamaica, Trinidad, Venezuela.
Biology.- The only biological data relating to this species was supplied by J. B. Karren, who took two males and three females that were walking on or just beginning tunnels in a fallen leguminous tree. Most specimens in collections were attracted to light.

Notes.- The above descriptions were based on the syntypes of scaber, sericeus, and opacithorax and on 40 other specimens from Central America. Of the four females specimens in the Zoologisches Museum at Berlin only the first two appear to be syntypes; the first of these is here designated as the lectotype of scaber Erichson, as cited above. Of seven male syntypes now in the Chapius collection at Brussels, the third is here designated as the lectotype of sericeus Chapuis, as cited above, because it was listed first in the original description.

Central American specimens have the elytral crenulations smaller and more numerous than those from South America. Many South American specimens, particularly the males, have the crenulations almost uniseriate on the dise and often as wide as the interstriae. Except for this character, specimens from the two areas do not appear to differ significantly. In general, but by no means consistently, the Central American representatives have been treated under scaber and the South American specimens under cristatus Chapuis ( $=$ radulosus Blandford and aspericollis Stromeyer), although the types of these names may be different species. Until the types are available for study, lunulatus Eggers and opacithorax Schedl are also tentatively treated here as variants of scaber. The syntypes of opacithorax fall well within the range or variability of this species.

## 5. Phlocoborus rudis Erichson

Phlocoborus rudis Erichson, I83f, Archiv Naturgesch 2(1):55 (Lectotype, female; Brazil; Zool. Mn. Berlin, present designation)
Phlocoborus elongatus Chapuis, 1869, Symopsis den Scolytides, p. I3 Holotype, male: Brazil; Brussels Mus.): Wood, 1973, Great Basin Nat. 33:180. Synomymy
Phlocoborus rugipennis Eggers, 1942, Arb. Morph. Taxon. Ent. Berlin-Dallem 9:271 IDolotype, female: San Salvador; U.S. Nat. Mus.); Wood, 1973, Great Basin Nat. 33:180. Synonymy
Diagnosis. - This very large species has the enlarged tibiae and other features used to characterize Phloeotrupes. In addition to those features this species has the pronotum almost smooth and shining, except for the punctures, and other characters summarized in the above key that distinguish it from other Central American species.

Female.- Length $10.2-11.7 \mathrm{~mm}, 1.8$ times as long as wide; color very dark reddish brown to black.

Frons shallowly impressed on lower half of area below eyes, convex above; impressed area with a median carina to epistomal margin; surface smooth, shining, punctures rather sparse, moderately large, deep; vestiture of fine, short hair confined to impressed area. Eyes subcontiguous above, separated by a distance about equal to one-third width of eye. Scape not reaching middle of eve.

Pronotum 0.68 times as long as wide; widest one-third length from base, sides rather weakly arcuate, feebly converging anteriorly, very broadly rounded in front; anterolateral angles with a few subasperate elevations indicated, remainder of surface smooth, shining except feeble reticulation indicated anteriorly, punctures moderately large, rather deep, irregular but close in most areas; a few minute bristles in anterior and lateral areas. Propleura with a large cavity on anterior half as in other Phloeoborus.

Elytra 1.3 times as long as wide, 2.1 times as long as pronotum; scutellar notch well developed, about five times as wide as scutellum; basal margins abrupt, crenulations obscurely indicated; striae impressed, punctures coarse, shallow; interstriae less than three times as wide as striae, convex, rather feebly reticulate, crenulations rather low, staggered, each about one-fourth to two-thirds as wide as interstriae. Declivity convex, steep; striae
deeper but not narrower than on disc, only slightly narrower than interstriae; interstriae reticulate, uniseriate crenulations extended to apex. Vestiture consisting of minute, interstrial bristles, each distinctly shorter than diameter of a strial puncture.

Male.- Smaller, about 7.5-8.8 mm, lower frons more strongly, more broadly impressed.

Distribution.- Guatemala to Brazil.
GUATEMALA: Trece Aguas, Alta Verpaz, O. F. Cook; Cayuga, IV-15, W. Schaus. EL SALVADOR: San Salvador, 1-V-57, P. A. Berry. COSTA RICA: Turrialba, Cartago, 13-V-51, O. L. Cartwright; Las Mercedes, F. Nevermann; Eggers adds Hamburgfarm on Río Reventazon, Limon, at light F. Nevermann, and Hacienda Pehlke, Colombia, by Pehlke. PANAMA: Barro Colorado 1sland, Canal Zone, 10-17-V-64, W. D. and S. S. Duckworth; La Chorrera, 18-V-12, A. Busck.

Biology.- As described for the genus.
Notes.- The above description was based on the Erichson series of rudis, on the holotypes of rugipennis and elongatus, and on 18 other specimens. Of the series of three females and two males now in the Zoologisches Museum in Berlin, it appears that only the first two, both females, were in the original series. The first specimen has been regarded as the type and is here designated as the lectotype of rudis Erichson, as cited above. The third specimen, a male, bears Eggers' identification label saying "Phloeoborus rudis Er. $\delta=$ elongatus Chap." The Erichson and Chapuis specimens were compared directly to one another and to my female topotypic homotype of rugipennis.

## Tribe TOMICINI

Tomicidae Thomson, 1859, Skandinaviens Coleoptera Synoptiskt Bearbetade 1:145 (Type-genus: Tomicus Latreille, 1802/3)
Hylurgini LeConte, 1876, Proc. Amer. Philos. Soc. 15:373 (Type-genus: Hylurgus Latreille, 1807)
Dendroctonides Nüsslin, 1912, Naturwiss. Zeitschr. Forst- und Landwirtschaft 1912:273 (Type-genus: Dendroctonus Erichson, 1836)
Xylechinides Nüsslin, 1912, Naturwiss. Zeitschr. Forst- und Landwirtschaft 1912:273 (Type-genus: Xylechinus Chapuis, 1869)

Anatomical features.- The frons is weakly sexually dimorphic, the eye is entire, the antennal funicle is 5 - to 7 -segmented, the club is symmetrical and feebly to moderately flattened, with sutures indicated, the procoxae are contiguous to narrowly separated, the precoxal costa on the prosternum is absent, the pronotum is unarmed (obscurely asperate in a few South American forms), the metascutellar area is separated from the postnotum by a distinct suture, and the sutural groove on the mesal surface at the base of the elytra continues to the base without a series of interlocking nodules and cavities.

Biological features. - All species are monogamous and phloeophagous. The parental tunnels are either biramous or, if monoramous, there is a conspicuous turning niche near the entrance tunnel. Eggs are placed in niches, except some Dendroctonus form grooves in which numerous eggs are placed. Larval mines usually follow a definite independent course without crossing, except some Dendroctonus feed in congress, thereby forming extensive, tabular chambers in the cambium region. Symbiotic relationships with fungi occur, but are not of a mycetophagous type.

Taxonomy.- This tribe apparently shares the same ancestry with the Hylesinini, but exhibits several more advanced characters. All the genera appear to have an American origin; all are more closely allied to the South American fauna than to that from other areas (except that the Eurasian Xylechinus pilosus (Ratzeburg) apparently was derived from North America rather recently). The tribe was not fully separable from the

Phloeosinini until the fusion of the postnotum to the scutellar area of the metanotum was discovered. The American genera of Tomicini are easily distinguished from one another; those from other parts of the world may be distinguished with difficulty.

## Genus PSEUDOHYLESINUS Swaine

Pseudohylesinus Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):11 (Type-species: Pseudohylesinus grandis Swaine = Hylurgus sericeus Mannerheim, original designation)
Diagnosis.- This genus is very closely related to Xylechinosomus Schedl, but it is distinguished by the less strongly impressed male frons, and by the simple sculpture of the elytral declivity. It is also allied to Xylechinus Chapuis, but Pseudohylesinus has seven segments in the antennal funicle.

Description.-Length $\quad 2.2-5.8 \mathrm{~mm}$, 2.1-2.5 times as long as wide; color dark brown to almost black, with abundant light and dark hairlike and scalelike setae.

Frons convex, with an arcuate, transverse impression at or just below middle, a median carina on lower half. Antennal scape elongate, shorter than 7 -segmented funicle; club conical to slightly flattened. Eye entire, elongate; rather finely granulate. Pronotum $0.7-1.3$ times as long as wide; sides strongly constricted just behind anterior margin; surface punctate, variously clothed by hair and scales. Scutellum small, depressed. Elytra 1.2-1.9 times as long as wide; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; basal margins each armed by about $10-15$ overlapping
crenulations; striate, interstriae tuberculate; declivity convex, rather steep, alternate interstriae often weakly elevated. Vestiture of ground cover of abundant scales and rows of longer, erect, interstrial bristles. Tibiae essentially as in Xylechinus.

Distribution. - Western North America; 11 species are known.

Biology. - These monogamous beetles attack limbs, bole, and roots of weakened or felled coniferous hosts, where they construct biramous parental galleries in the cambium region. According to Bright (1969), the female initiates the attack before the male arrives at the new host. Eggs are deposited in individual niches in the phloem. Larval mines are moderately long, more or less straight, and almost entirely in the phloem. They radiate approximately at right angles from the
parental tunnels. The flight period begins as early as March and continues at a relatively high level until September. One generation apparently is the rule in Canada, with up to two and a partial third generation in the southwestern United States. Individual parents may reemerge to produce a second or even a third brood. There are three larval instars.

Notes.- Schedl (1966) indicated that Pseudohylesinus Swaine, 1917, and Xylechinosomus Schedl, 1963, are both junior subjective synonyms of Pteleobius Bedel, 1888. Although the first two genera are very closely related and, perhaps, doubtfully distinct from one another, they are fundamentally distinct from and quite unrelated to Pteleobius. The relationship to Xylechinus is much closer.

Key to the Species of Pseudohylesinus
(Modified from Bright 1969:15)

1. Frontal rectangle (Blackman 1942:29) 0.9-1.0 times as long as wide; body 2.1-2.4 times as long as wide; segment 1 of antennal club little if any longer than 2

- Frontal rectangle 1.0-1.3 times as long as wide; body 2.0-2.2 (2.2-2.4 in granulatus) times as long as wide; segment 1 of antennal club conspicuously longer than 2
2(1). Crenulations on elytral bases from striae 5 to humeral angle high, acutely pointed; declivital interstriae 9 usually moderately elevated, commonly more strongly serrate; interstrial hairlike setae finer, short; parental galleries longitudinal
- Crenulations on elytral bases usually not higher or more acutely pointed in lateral areas; declivital interstriae 9 issually less strongly elevated, less coarsely serrate; interstrial hairlike setae rather short, coarse; parental galleries transverse
3(2). Declivital interstriae I and 3 weakly or not at all elevated, 2 as wide as 1 or 3, 1-3 equally armed by fine granules; British Columbia and Alberta to California and Chihuahua; Pseudotsuga menziesii, Tsuga; 2.3-2.9 mm

1. nebulosus nebulosus (LeConte)

- Declivital interstriae 1 and 3 moderately elevated, finely serrate, 2 impressed, devoid of granules, narrower than 1 or 3; S California; Pseudotsuga macrocarpa; 3.0-3.5 mm

2. nebulosus serratus Bruck

4(2). Declivital interstriae 2 devoid of granules and hairlike setae; interstrial bristles about half as long as distance between rows

- $\quad \begin{aligned} & \text { Declivital interstriae } 2 \text { armed by a few small granules and by a row of hairlike } \\ & \text { bristles; interstrial bristles almost as long as distance between rows .......................... } 6\end{aligned}$

5(4). Color pattern of pale and light brown scales, less commonly (northern areas) with some dark brown patches, pale scales often predominate, in patches or not; S Oregon to California; Abies; 2.8-3.7 mm

- Color pattern predominantly of dark brown scales, with small patches of pale scales; Washington to central Oregon; Abies procera; $2.6-3.7 \mathrm{~mm}$

4. dispar pullatus Blackman

6(4). Inner surface of large strial punctures reticulate; interstrial scales very small, predominantly dark; pronotum densely punctured; Michoacán; Abies religiosa; 4.4-5.8 mm 5. magnus Wood

- Strial punctures small, inner surface smooth; interstrial scales moderately large, predominantly pale or light brown; pronotal punctures close deeper; smaller 7
7(6). Smaller; submarginal crenulations near bases of interstriae 5 and 6 almost always uniseriate, less crowded; lower frons more coarsely, more deeply punctured; interstrial tubercles on declivity averaging higher, more acutely pointed; Utah to Arizona and New Mexico; Abies concolor; 2.7-3.8 mm

## 6. maculosus Blackman

- Larger; submarginal crenulations at bases of interstriae 5 and 6 crowded, usually confused; lower frons finely, more shallowly punctured; interstrial granules on declivity not as high, more broadly rounded; Michoacán to Tlaxcala and Oaxaca; Abies religiosa; 3.4-4.5 mm

7. variegatus (Blandford)

8(1). Female pronotal setae hairlike, male also with slender scales; interstrial bristles very fine (except granulatus), shorter, submarginal interstrial crenulations more numerous, confused in both sexes; mostly slightly larger

- Female pronotal setae hair- and scalelike, male scales rather broad; interstrial bristles slightly longer, stout; subcrenulate interstrial granules uniseriate (except sericeus), occasionally slightly confused at base in female; mostly somewhat smaller

| 9(8). | Larger; pronotal punctures averaging slightly larger, deeper, most specimens with lateral margins of lateral punctures granulate to subasperate; strial punctures usually larger, deeper, striae often as wide as interstriae; interstrial bristles rather coarse; body 2.2-2.4 times as long as wide; Alaska to California; Abies; $4.0-5.4 \mathrm{~mm}$ $\qquad$ 8. granulatus (LeConte |
| :---: | :---: |

- Smaller; pronotal punctures averaging smaller, less strongly impressed, rarely with their lateral margins granulate; strial punctures usually smaller; striae narrower than interstriae; interstrial bristles more slender; body stouter, 2.0-2.1 times as long as wide; Alaska to California; Tsuga, Abies; 2.6-4.0 mm

9. tsugae Swaine
$10(8)$. Interstrial subcrenulate granules more abundant and confused at bases; female discal interstrial scales each one to two times as long as wide; arcuate transverse frontal impression poorly developed in both sexes, frontal rectangle 0.95 (female) - 1.06 (male) times as long as wide

- Interstrial granules usually not more abundant or confused toward bases (confused in some female sitchensis); female discal interstrial scales more than twice as long as wide; transverse frontal impression well developed in both sexes, frontal rectangle 1.03 (female) - 1.20 (male) times as long as wide
$11(10)$. Female pronotal scales (except near scutellum), slender, varying from almost hairlike to about eight times as long as wide, their apices subacute not divided except near scutellum; male pronotal scales two to six times as long as wide; Washington, Oregon; 2.7-3.8 mm 10. nobilis Swaine

[^2]12(10). Pronotal scales more slender, 4-8 times as long as wide in female, 2-3 in male; interstrial granules averaging larger; frontal rectangle 1.0 times as long as wide in female, male 1.2 times as long as wide; Alaska to California; Picea sitchensis; $2.5-3.1 \mathrm{~mm}$ 12. sitchensis Swaine

- Pronotal scales stouter, 2-5 times as long as wide in female, subcircular in male; interstrial granules averaging smaller; frontal rectangle 1.06 times as long as wide in female, male 1.4 times as long as wide; British Columbia to California; Pinus; 2.2-2.8 mm

13. pini Wood

## 1. Pseudohylesinus nebulosus nebulosus (LeConte) <br> Figs. 22, 52, 53

Hylesinus nebulosus LeConte, 1859, Proc. Acad. Nat. Sci. Philadelphia 5:285 (Holotype, male; Table Mountain, California; Mus. Comp. Zool., 1019)
Pseudohylesinus nebulosus: Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):75
Pseudohylesinus nebulosus nebulosus: Bright, 1969, Univ. California Pub. Ent. 54:16.
Diagnosis.- This is the smallest (except pini), most slender, and most widely distributed species in the genus; additional distinguishing characters are included in the above key.

Male.- Length 2.3-2.9 mm, 2.3-2.4 times as long as wide; color very dark brown, with a variegated surface pattern formed by dark and light scales and hair.

Frons broadly convex, a weak transverse impression just above epistoma, a second weak, transversely arcuate impression near middle; lower half with a low, acutely elevated, median carina; surface shining, punctures close, rather deep, moderately fine on lower half, coarse above, devoid of granules; frontal rectangle 1.1 times as long as wide; vestiture of fine, short, moderately abundant hair.

Pronotum 0.83 times as long as wide; widest near middle, sides on basal half weakly arcuate, almost parallel, abruptly narrowed anteriorly to strong constriction on anterior fourth, rather broadly rounded in front; surface shining, with dense, moderately deep punctures; interspaces about one-third as wide as diameter of a puncture. Vestiture of erect, sparse hair and recumbent scales; scales on disc mostly as long as wide.

Elytra 1.7 times as long as wide; sides almost straight and parallel on less than basal two-thirds, gradually converging on posterior two-thirds, median third at apex very broadly rounded; anterior margin armed by about 11 rather coarse crenulations, extreme lateral
one or two larger and pointed, a few submarginal crenulations on interstriae 2-6; striae weakly impressed, punctures moderately coarse, deep; interstriae almost twice as wide as striae, each with a central row of uniseriate granules of moderate size, remaining surface with numerous, fine, confused, very slightly crenulate punctures. Declivity convex, moderately steep; interstriae 1 and 3 feebly, 9 more strongly, convex, 2 narrower than 1 and 3, feebly depressed, tubercles on 1 and 3 as on disc, evidently smaller on 2 or 4-8, a row of rather coarse, pointed denticles on 9 . Densely clothed by a ground cover of scales, each slightly longer than wide, narrowly rounded at their apices; interstriae each with a uniseriate row of erect, short, slender, bristles, each bristle shorter than distance between rows.

Female.- Similar to male except frontal rectangle 0.80 times as long as wide; pronotal scales more elongate, subpalmately subplumose; apices of elytral scales usually acuminately angulate; color pattern less well defined.

Distribution.-S British Columbia and Alberta to Chihuahua, except S California.

CANADA: Alberta: Banff, Jasper, Maycroff, Waterton Lakes. British Columbia: Aspen Grove, Cherry Ck., Chilcotin, Columbia Lake, Cowishan Lake, Duncan's, Genoa Bay, Hotel Lake at Pender Harbor, Indian Meadows and Merritt at Midday Valley, Kaslo, Massett, Momich Ck., Nelson, Peachland, Vancouver, Vangard, Vernon, Wellington, West Lake on Nelson Isl., Williams Lake. USA: Arizona: Chiricahua Mts., Flagstaff, Hannagan Camp in Greenlee Co., Jacol)'s Lake, Miller Canyon in Huachuca Mts., Pinaleno Mts., Prescott N. F., San Francisco Mts., Santa Catalina Mts., Walker, Williams. California: Big Spring in Plumas Co., Calistoga, Carville, Cascade House, Costella, Crescent City, Cypress Ridge in Marin Co., Del Norte, Dutch Flat in Placer Co., Ft. Seward, Georgetown in El Dorado Co., Gasquet. Happy Camp, Mill Valley, Mt. Tamalpais, Monterey, Orick, Oreleans, Plantation, San Francisco, Shingleton, Trinity. Colorado: Colorado Springs, Dolores, Durango, Estes Park, Foxton, Rist Canyon in Larimer Co. Idaho: Cedar Mt., Centerville, Coeur d'Alene, Franklin Basin Road in Cache N. F., Grimes Pass,

Hailey, Moscow Mt., Placerville, Sand Point. Montana: Bear Paw Mts., Columbia Falls, Helena, Rocky Boy Indian Res. in Hill Co. New Mexico: Capitan, Clouderoft, Las Vegas Hot Springs, Sandia Mts. Oregon: Numerous localities from every comnty in the state. Utah: Alta, Beaver Canyon in Beaver Co., Bryce Canyon N. P., Henry Mts., Logan Canyon, Mt. Timpanogos. Washington: Numerous localities from every county in the state. MEXICO: Chihuahua: La Magdalena, San Juanito.

Host.-Pscudotsuga menziesii, less commonly in Tsuga heterophylla.

Brology. - The bole and limbs of recently cut, injured, or unthrifty trees are selected for attack. The longitudinal parental galleries are mostly in the phloem. Larval mines wander erratically and may be unusually long. The winter may be passed either as larvae or adults in Utah.

Notes.- The above treatment was based in the male holotype and on 712 other specimens.

## 2. Pseudohylesinus nebulosus serratus Bruck

Pseudohylesiuns serratus Bruck, 1936, Bull. So. California Accad. Sci. 35:37 (Holotype, male; West Fork of San Cabriel Canyon, Los Angeles Co., California; Ohio State Univ. Coll.)
Pseudohylesinus nebulosus serratus: Bright, 1969, Univ. California Pub. Ent. 54:18
Diagnosis.- This subspecies is distinguished as indicated in the above key.

Male.-Length $3.0-3.5 \mathrm{~mm}, 2.4$ times as long as wide.

Essentially as in n. nebulosus except declivital interstriae 1 and 3 rather strongly elevated, 2 depressed and distinctly narrower than 1 or 3 , tubercles on $1,3,5,7$, and 9 averaging larger.

Female. - Similar to male but differing much as in female $n$. nebulosus except that elytral scales appear subpalmately subplumose.

## Distribution.- Coastal California from

 Santa Barbara County southward.USA: California: Big Pines, 14-II-57, D. E. Bright; "S. Madre" in Santa Barbara Co.; Henniger Flats, 22-VI-40, Pseudotsuga macrocarpa, C. R. Bruck; Lytle Ck. in San Bernardino Co.: Switzers Camp, San Gabriel Mts., Santa Barbara Co., I8-IV-62, P. macrocarpa, D. E. Bright; Santa Monica; West Fork, San Cabriel Canyon, Los Angeles Co., 29-XII-34, P. macrocarpa, R. Kessinger.
Host.- Pseudotsuga macrocarpa.
Biology.- Evidently as in n. nebulosus.
Notes. - The above treatment was based on the holotype, allotype, seven paratypes, and 11 other specimens.

The anatomical differences between $n$. nebulosus and $n$. serratus are greater than between most species of the genus. In all probability they are specifically distinct. However, when all factors are considered, particularly the hosts and distribution, it appears best to follow Bright and treat them as subspecies until additional information is available.

## 3. Pseudohylesinus dispar dispar Blackman

Pseudohylesinus dispar Blackman, 1942, U.S. Dept. Agric. Misc. Publ. 46I:II (IIolotype, female; Veronia, Oregon; U.S. Nat. Mus., 54026)
Pseudohylesinus dispar dispar: Bright, 1969, Univ. California Publ. Ent. 54:20
Diagnosis.- This species is distinguished from n. nebulosus (LeConte) by the larger average size, by the less strongly developed, less pointed lateral crenulations at the bases of the elytra, by the less strongly elevated,

Fig. 52. Pseudohylesinus n. nebulosus: Dorsal aspect. (After Bright and Stark 1973:149.)
less strongly serrate declivital interstriae 9 , by the shorter interstrial bristles, by the hosts, and by the transverse parental galleries.

Male.- Length $2.8-3.7 \mathrm{~mm}, 2.2$ times as long as wide; color very dark brown, with a variegated surface pattern formed by light and dark scales, light colored scales predominating.

Frons essentially as in n. nebulosus except transverse impression just above epistoma slightly deeper; frontal rectangle 1.0 times as long as wide. Pronotum essentially as in $n$. nebulosus except pale scales more evident.

Elytra 1.6 times as long as wide; outline as in n. nebulosus except more broadly rounded behind; basal crenulations not higher laterally or pointed; sculpture essentially as in $n$. nebulosus except interstrial tubercles more nearly transversely crenulate, declivity somewhat more broadly convex, with interstriae 1 , 3 , and 9 more feebly elevated; declivital tubercles on interstriae 3,5 , and 7 evidently averaging slightly larger; interstriae 2 as wide as 1 or 3, usually not impressed. Erect interstrial bristles short, their length equal to about half distance between rows of bristles. Pale scales predominate over tan and occasional darker scales.

Female.- Similar to male except frons more strongly convex; frontal rectangle 0.90 times as long as wide; pronotal scales up to twice as long as wide, their margins tending to be fringed; elytral scales more elongate, distinctly less than twice as long as wide, their margins fringed.

Distribution.-S Oregon to California.
USA: California: Numerous records from the counties of Amador, Eldorado, Fresno, Lassen, Madera, Mariposa, Modoc, Placer, Plumas, Shasta, Siskiyou, Tuohume. Nevada: Washoe Co.

Intermediate specimens were from coumties in Oregon: Harney, Jackson, Klamath.

Hosts.- Abies amabilis, A. concolor, A. grandis, A. maganifica, and Tsuga mertensiana.

Biology.-- Transverse parental galleries are constructed in the bole and larger limbs. One sample was taken from large roots.

Notes.- The above treatment was based on 339 specimens.

There appears to be a clinal gradient in the color of this species begimning at the south end of the distribution where scales are a mixture of pale (almost white) and light
tan. Toward northern California the patches of white scales become smaller in size as the tan scales increase in number and intensity of color, some of them being rather dark brown. In material from southern Oregon, the tan scales have entirely been replaced by dark brown scales. Specimens from central Oregon to Washington have the white scales reduced to smaller patches, with dark scales covering the remaining areas. Bright (1969:21), apparently arbitrarily, placed all specimens from Abies procera in a northern subspecies, $d$. pullatus, and all other material in a southern subspecies, d. dispar. His distribution map (p. 19), however, shows such extensive overlap, with almost no exclusive range for the northern race, that his argument for their continued recognition is virtually eliminated. However, as stated by Bright (p. 21), the northern and southern extremes are so strikingly different some recognition should be given to them. In view of the material before me, I follow Bright's division of the species and recognize all California specimens as $d$. dispar. Specimens from the southern third of Oregon exhibit a transition in pattern and color in which many individuals are not clearly assignable to either race. Specimens from central Oregon northward I assign to $d$. pullatus, although occasional specimens in a series are not as dark as one making an identification might wish.

## 4. Pseudohylesinus dispar pullatus Blackman

Pscudohylesinus pullatus Blackman, 1942, U.S. Dept. Agric. Misc. Publ. 461:9 (Holotype, female: Mount Rainier Nat. Pk., Washington; U.S. Nat. Mus., 54025)
Pseudohylesinus dispar pullatus: Bright, 1969, Univ. California Pull. Ent. 54:21
Diagnosis. - For distinguishing characters refer to the above key and to the taxonomic notes under d. dispar Blackman.

Male.- Length $2.6-3.7 \mathrm{~mm}, 2.2$ times as long as wide; color very dark brown, with surface color pattern of predominantly dark brown scales with small scattered patches of white scales.

As in d. dispar except for the scale color pattern.
Female.- Similar to male except differing as female d. dispar differs from male.

Distribution.- Central Oregon to British Columbia.

CANADA: British Columbia: Vancouver. USA: Oregon counties: Baker, Benton, Clackamas, Columbia, Douglas, Hood River, Lane, Linn, Umatilla. Washington comnties: Pierce, Skamania.

Hosts.- Abies amabilis, A. grandis, and A. procera.

Notes. - The above treatment was based on the holotype, on several paratypes, and on 54 other specimens. The status of this subspecies is discussed under d. dispar.

## 5. Pseudohylesinus magnus Wood

Pseudohylesimus magmus Wood. 1956, Canadian Ent. 88:247 (Holotype, female; 25 miles or 40 km W Ciudad Hidalgo, Michoacán, Mexico; Snow Ent. Mus., Univ. Kansas)
Diagnosis. - The large size, the black color, and the rugose-reticulate inner surface of the strial punctures distinguish this species from other representatives of the genus.

Male.- Length 4.4-5.8 mm, 2.3 times as long as wide; color black, with surface pattern of predominantly black scales and small patches of white scales.

Frons broadly, evenly convex above, lower half more nearly flattened below weak, arcuately, transversely impressed line, rather strongly, transversely impressed just above epistoma; a fine, subacutely elevated median carina on lower half; vestiture of rather short, coarse, moderately abundant hair, on upper half intermixed with scales; frontal rectangle 1.0 times as long as wide. Segment 1 of antennal club only slightly longer than 2 or 3 .

Pronotum 0.82 times as long as wide; widest at base, sides weakly arcuate, converging only slightly before rather strong constriction just behind broadly rounded anterior margin; surface with dense, small, moderately deep punctures, except subgranulate on anterior fifth, partly obscured by scales. Vestiture of moderately abundant black scales, with small patches of white scales toward base; each scale about twice as long as wide.

Elytra 1.6 times as long as wide, 2.4 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather broadly rounded behind; anterior margins each armed by about 12 low crenulations; striae rather weakly impressed, punctures moderately large, deep, their interiors conspicuously ru-gose-reticulate; interstriae about one and
one-half times as wide as striae, crenulations much as in other species but small, narrow, punctures small, deep, rather abundant. Declivity convex, steep; interstriae 1,3 , and 9 weakly convex toward apex, otherwise essentially as on disc. Interstriae covered by abundant scales, each scale about twice as long as wide; erect interstrial bristles rather stout, half as long as distance between rows.

Female.- Similar to male except frons less strongly convex, scales absent from upper frons but present on vertex; scales evidently always absent from pronotal disc; elytral scales slightly smaller, evidently more abundant.

Distribution.- Michoacán.
MEXICO: Michoacán: 25 miles or 40 km W Ciudad Hidalgo, 15-VII-53, 2900 m , Abies religiosa, S. L. W'ood; 33 miles or 53 km E Morelia, 14-VI- 65.3000 m, No. 45. A. religiosa, S. L. Wood.

Host.-Abies religiosa.
Biology. - The lower bole of very large trees is selected for attack. This species is aggressive and probably is capable of killing overmature trees. The transverse parental galleries are straight and longer than in other species. After this species was well established it was joined by the less aggressive cariegatus (Blandford). Larval mines evidently wander as in other species; only first instar larvae were observed.

Notes.- The above treatment was based on two female paratypes and on 34 other specimens.

## 6. Pseudohylesinus maculosus Blackman

Pseudohylesinus maculosus Blackman, 1942, U.S. Dept. Agric. Misc. Publ. 461:12 (Holotype, female; Chiricahua Mts., Arizona; U.S. Nat. Mus, 5402 -)
Diagnosis.- This species superficially resembles sericeus (Mannerheim), to which it is not closely related; it is distinguished by characters presented in the above key.

Male.- Length $2.7-3.8 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown, with a variegated surface pattern of pale, tan, and brown scales.

Frons with general contours as in magnus Wood except lower half slightly more convex; surface shining, punctures rather coarse, close, deep, only slightly smaller on lower half; vestiture of short, moderately abundant hair; frontal rectangle 1.0 times as long as
wide. Antennal club similar to but more elongate than in dispar Blackman.

Pronotum 0.82 times as long as wide; outline and surface about as in magnus except disc more convex, median line evident; scales large, moderately abundant, each about twice as long as wide.

Elytra 1.6 times as long as wide, 2.4 times as long as pronotum; outline as in magnus; basal margins each armed by 12 crenulations, lateral ones slightly higher; striae slightly impressed, punctures rather large, deep; interstriae about one and one-half times as wide as striae, crenulations coarse, high, those at bases of 2-4 larger, confused, uniseriate on bases of 5 and 6 , punctures fine, deep, rather abundant. Declivity rather steep, convex; interstriae about equally, weakly convex except 9 slightly higher, 2 slightly depressed; crenulations modified to slender, rather widely spaced denticles, denticles slightly larger on odd-numbered interstriae. Vestiture of ground cover of abundant scales, each only slightly longer than wide, pale and brown about equal in numbers, arranged in irregular patches, a few $\tan$ scales on some specimens; bristles short, rather stout, each about half as long as distance between rows, bristles present on declivital interstriae 2.

Female.-Similar to male except frons more strongly convex; pronotal scales less abundant, each about four times as long as wide, many of them subpalmately subplumose.

Distribution.- Utah to Arizona and New Mexico.

USA: Arizona: Grand Canyon N. P., 30-V-69, A. lasiocarpa, W. G. Harwood; Jacob's Lake, 31-V-69, A. concolor, A. lasiocarpa, W. G. Harwood; Graham Mts., 28 -VII-33, lot 64, Parker; Crand Canyon; Mt. Lemon, Pima Co., 5-V'Ill-68, A. lasiocarpa, D. E. Bright: Rustler's Pk, Chiricahua Mts., 7-VI-69, A. concolor, S. L. Wood; Miller Canyon, Huachuca Mts., 7-VI-69, A. concolor, S. L. Wood. Pinaleno Mts., 15-VII-68, A. concolor, D. E. Bright; Santa Catalina Mts., 5-V1II-68, A. concolor. D. E. Bright. New Mexico: Clouderoft, 2-V1-69, 2900 m , No. 58, A. concolor, S. L. Wood. Utah: Payson Canyon, 25-V11-62, Abies concolor, S. L. Wood; Beaver, 22-1V-50, A. concolor, S. L. Wood.

Hosts.-Abies concolor, rare in A. lasiocarpa.

Biology.- The bole of fallen, cut, or unthrifty trees is selected for attack. Parental tunnels are transverse. They are found most commonly at the butt of dying standing trees.

They can reproduce in Alpine fir, but probably cannot sustain a breeding population in it.

Notes. - The above treatment was based on the holotype and on 124 other specimens.

Bright (1969:22) treated maculosus as a synonym of variegatus (Blandford), but included (p. 37) a note from my observations suggesting a need for further study of these forms. In view of the very slight anatomical differences presented above, including the distinctly smaller average size, and the difference in larval habits, I prefer to recognize them as specifically distinct. The larval mines in maculosus are always exposed at the cambium on the surface of peeled bark; they are comparatively short and wander rather indiscriminantly.

## 7. Pseudohylesinus variegatus (Blandford)

Hylastes caricgatus Blandford, 1897, Biol. Centr. Amer.. Coleopt. 4(6):I45 (Holotype, female, erroneously said to have come from Volcán de Chiriquí, Panama; British Mus. Nat. Hist.)
Pseudohylesinus mexicanus Blackman, 1942, U.S. Dept. Agric. Misc. Pub. 461:13 (Holotype, female; Distrito Federal, Mexico: U.S. Nat. Mus., 54028); Bright and Stark, 1973, Univ. California Pub. Ent. 54:22. Synonymy
Diagnosis.- This species is very similar to maculosus Blackman, but it is distinguished by the larger average size, by the more abundant, confused, submarginal crenulations at the bases of interstriae 5 and 6 , by the more finely, more shallowly punctured lower half of the frons, by the slightly smaller, more rounded interstrial tubercles on the declivity, and by the xylophagous mining habit of the larger larvae.

Male.- Length 3.4-4.5 mm, 2.2 times as long as wide; color dark brown, with a variegated surface pattern of pale to tan and dark brown scales.

In addition to characters mentioned in the above diagnosis, this species differs from maculosus in having some scalelike setae on upper half of frons; and more dark brown scales present on elytra.

Female.-Similar to male except frons more strongly convex; scalelike setae absent from upper half of frons; pronotal scales mostly abraded, each about four times as long as wide, mostly subpalmately
subplumose; interstrial scales largely abraded,more slender, mostly subplumose.

Distribution.- Michoacán to Tlaxcala and Oaxaca.

MEXICO: Hidalgo: El Chico, Pachuca. Mexico: 6 km W Río Frío, 14-VII-53, Abies religiosa, S. L. Wood. Michoacán: 33 miles or 53 km E Morelia, 14-VI-65, 3000 m, No. 48, A. religiosa, S. L. Wood. Nuevo León: Cerro Potosí, 3-V-71, 3300 m, Abies, D. E. Bright. Oaxaca: 53 miles or 85 km S Valle Nacional, $24-\mathrm{V}-71$, Abies religiosa, D. E. Bright. Tlaxcala: 18 km N Tlaxco, 2900 m , No. 21, A. religiosa, S. L. Wood.

Host.- Abies religiosa.
Biology.- This species was common in the bole of large fallen, cut, and unthrifty trees. The parental galleries are transverse and rather long. Larval mines are almost straight, very long and parallel to the grain of wood; for about half their length they are visible in the phloem on the surface of peeled bark, then they turn abruptly into the wood. The remaining half of their length is about 1 cm below the wood surface and parallel to the fibers; pupation occurs in the wood.

Notes.- The above treatment was based on 123 specimens.

The holotype is labeled Volcan de Chiriqui, Panama, but Abies does not grow south of Honduras. This specimen probably came from southern Mexico or Guatemala.

## 8. Pseudohylesinus granulatus (LeConte)

Hylastes granulatus LeConte, 1868, Trans. Amer. Ent. Soc. 2: I75 (Holotype, male; blue disk signifying Oregon: Mus. Comp. Zool., 956)
Pseudolylesinus granulatus: Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14 (2):74
Diagnosis.- This species is distinguished from tsugae Swaine by the larger size, by the larger, deeper, subasperate, pronotal punctures, and by the more slender body form.

Male.- Length $4.0-5.4 \mathrm{~mm}, 2.2-2.4$ times as long as wide; color dark brown, with a sparse covering of light and dark scales.

Frons about as in maculosus Blackman except more elongate, punctures somewhat coarser, impressed area above epistoma slightly stronger and more extensive; frontal rectangle 1.1 times as long as wide. Segment 1 of antennal club as long as 2 and 3 combined.

Pronotum 0.88 times as long as wide; widest just behind middle, sides on basal twothirds rather strongly arcuate, rather strongly
constricted on anterior third, broadly rounded in front; surface shining, rather coarsely, closely, deeply punctured, lateral margins of most punctures at least weakly subasperate. Vestiture of sparse, short, rather stout hair; a few scales at base, each about four times as long as wide.

Elytra 1.6 times as long as wide, 2.2 times as long as pronotum; outline about as in maculosus; striae weakly impressed, punctures rather coarse, very deep, smaller toward base; interstriae about as wide as striae, weakly convex, each armed by a row of coarse, tuberculate crenulations, crenulations confused toward base on $2-5$, punctures fine, subgranulate, confused, moderately abundant. Declivity steep, convex; interstriae 1,3, and 9 rather weakly convex, 2 depressed, fine tubercles on odd-numbered interstriae. Vestiture of sparse, slender scales, each about four times as long as wide, more abundant on declivity; erect bristles rather short, stout, each about half as long as distance between rows, absent on 2 on declivity.

Female.-Similar to male except frons more strongly convex; pronotum devoid of scales; scales on elytral dise largely abraded.

Distribution.-Alaska to California.
ALASKA: "Nauacin." CANADA: British Columbia: Bowser, Nonausco, Steelhead, 12 miles or 19 km S Tofino. USA: California: Alpine Lake, Badger Pass, Carmel, Chester, Cisco, Eldorado Co., Eureka, Facht, Fallen Leaf Lake, Fieldbrook, Giant Forest in Tulare Co., Humboldt Co., Kaweah, King's River in Fresno Co., Meadow Valley in Plumas Co., Mendocino Co., Philips. Placer Co., Sequoia N. P., Shingletown, Trinidad, Tuolumne Co., Yosemite Valley, Idaho: Couer d'Alene, Moscow. Oregon: Blue Mts., Bly. Branden, Cannon Beach, Corvallis, Hood River, Mary's Peak, Odell Lake, Prineville, Santiam Junction, Stayton, Sweet Home in Linn Co. Washington: Carlyon Beach, Clear Lake, Kanaskut, La Grande, Lyman, Mineral, Moclips, Mt. Rainier, Seattle, Satsop.

Hosts.-Abies amabilis, A. grandis, A. lasiocarpa, A. magnifica, A. procer, and Tsuga Heterophylla.

Biology. - This species constructs transverse parental galleries at the base of unthrifty standing trees or near the ground in large cut or fallen trees.

Notes. - The above treatment was based on the male holotype and on 94 other specimens.

## 9. Pseudohylesinus tsugae Swaine

Pseudohylesinus tsugae Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1): 11 (Holotype, fenrale; Vancouver, British Columbia; Canadian Nat. Coll., 9338)
Pseudohylesinus obesus Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):15 (Holotype, female; Inveruess, British Columbia; Canadian Nat. Coll., 9341); Bright, 1969, Univ. California Publ. Ent. 54:25. Synomymy
Pseudohylesinus keeni Blackman, 1942, U.S. Dept. Agric. Misc. Publ. 461:17 (Holotype, female; Cannon Beach, Oregon; U.S. Nat. Mus., 20569); Bright, 1969, Univ. California Publ. Ent. 54:25. Synonymy
Pseudolylesinus similis Blackman, 1942, U.S. Dept. Agric. Misc. Publ. 461:18 (Holotype, female; Paradise Valley, Washington; U.S. Nat. Mus., 54030 ); Bright, 1969, Univ. California Publ. Ent. 54:25. Synonymy
Diagnosis.- This species is allied to granulatus (LeConte), but it is distinguished by the smaller size, by the stouter body, by the smoother, more finely punctured pronotum, by the narrower striae, and by the slender interstrial bristles.

Male.- Length 2.6-4.0 mm, 2.0-2.1 times as long as wide; color dark reddish brown, with an obscure surface pattern of pale and dark cinereus scales.

Frons more broadly convex than in granulatus, with transverse, arcuate impression near middle stronger, carina higher; frontal rectangle 1.1 times as long as wide. Segment 1 of antennal club much longer than either 2 or 3 .

Pronotum 0.76 times as long as wide; widest near base, sides moderately arcuate on posterior two-thirds, strongly constricted on anterior fourth, broadly rounded in front; surface shining, punctures moderately small, dense, rather deep, their lateral margins usually not at all granulate. Vestiture of very slender, pale scales, each at least eight times as long as wide, and slightly longer, suberect hair of about equal abundance.

Elytra 1.5 times as long as wide, 2.2 times as long as pronơtum; outline about as in maculosus Blackman; striae distinctly impressed, punctures rather small, very deep; interstriae twice as wide as striae, distinctly convex, crenulations rather fine, confused toward base on $2-7$, punctures minute, confused, subgranulate, rather abundant. Declivity steep, convex; essentially as in granulatus.

Vestiture of abundant ground cover of small scales, each about twice as long as wide, mostly pale, with darker areas; interstrial bristles fine, length very slightly more than half as great as distance between rows.

Female.-Similar to male except frons slightly more strongly convex; pronotum devoid of scales except for a few palmately pulmose scales at base; elytral scales much less abundant (usually abraded), each about four to six times as long as wide.

Distribution.-S Alaska to N California.
ALASKA: Junean. CANADA: British Columbia: Bowser, Duncan, Emerald Mine, Grouse Mt., Inverness, Mt. Mahleach, Nanaimo, Stanley Park, Steelhead, Vancouver, Victoria, Whonnock Lake. USA: California: Crescent City, Fieldbrook. Oregon: Astoria, Batterson, Boyer, Cannon Beach, Clatsop, Corvallis, Crater Lake, Gold Lake, Marchfield, Marion Forks, Mary's Peak, Mohler, Reedsport, Waldport. Washington: Concrete, Glacier, Hoquiam, Mountlake Terrace, Naselle, Paradise Valley, Sappho, White River.

Host.- Tsuga heterophylla, T. mertensiana, and less commonly in Abies procera.

Biology.- The parental galleries are basically transverse. These beetles attack the bole and limbs as small as 5 cm in diameter. They normally attack cut, broken, or fallen trees.

Notes.- The above treatment was based on the holotypes of tsugae, obesus, similis, and keeni, and on 126 other specimens.

## 10. Pseudohylesinus nobilis Swaine

Pseudohylesinus nobilis Swaine, 1917. Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):12 (Lectotype, female; Santiam N. F., Oregon; Canadian Nat. Coll., 9340, designated by Bright, 1967, Canadian Ent. 99:679)
Pseudohylesinus furnissi Blackman, 1942, U.S. Dept. Agric. Misc. Publ. 461:21 (Holotype, female; Mount Rainier N. P., Washington; U.S. Nat. Mus., 54031); Bright, 1969, Univ. California Publ. Ent. 54:27. Synonymy
Diagnosis.- This species is distinguished from sericeus (Mannerheim) by the more slender scales on the pronotum.

Female. - Length 2.7-3.8 mm, 2.1 times as long as wide; as in sericeus except pronotal scales slender, varying from almost hairlike to about eight times as long as wide, except stouter near scutellum; strial punctures tending to be larger (not consistent).

Male.-- Similar to male sericeus except pronotal scales two to six times as long as wide, their apices usually not palmately divided.

Distribution.- Oregon and Washington.
USA: Oregon: Bandon, Abies amabilis; Crater Lake N. P., A. amabilis; Gold Lake, Willamette N. F., 16-V161, A. amabilis, S. L. Wood; Lost Lake, Hood River Co., 25-VII-64, A. amabilis, D. E. Bright; Mary's Peak, Siuslaw N. F., 19-VI-61, A. procera. S. L. Wood; Mt. Hood; Santiam Pass, Linn Co., 19-V1-61, A. amabilis, S. L. Wood. Washington: Easton; Longmire, 23-V-35, Hopk. U.S. 20579-A, A. amabilis, F. P. Keen; Mt. Rainier N. P., A. procera; Spirit Lake, A. amabilis; White Pass, Yakima Co., 20-V111-62, A. grandis, D. E. Bright; White River; Yakima Park.

Hosts.- Abies amabilis, and A. procera.
Biology.- Basically as in sericeus, but the parental galleries vary from transverse to subvertical.

Notes.- This species is exceedingly difficult to distinguish from sericeus. Both species vary considerably and often cannot be recognized unless series are available for study. The above treatment was based on the holotype of nobilis, on my homotype, on two specimens from Blackman's series, on four from Bright's series, and on 209 other specimens. At the time the holotype of furnissi was examined I did not regard nobilis as a distinct species; consequently, I rely on Bright's (1969:28) synonymy for treatment of this name.

## 11. Pseudohylesinus sericeus (Mannerheim)

Hylurgus sericeus Mannerheim, 1843, Moskov. Obshch. 1sp. Prirody, Otd. Biol. Biul. (Bull Soc. 1mp. Nat. Moscou) 16(2):296 (reprint p. 124) (Holotype, female; Sitka, Alaska; Univ. Zool. Mus., Helsinki)
Pseudohylesinus sericeus: Wood, 1969, Great Basin Nat. 29:116, 31:69
Pseudohylesinus grandis Swaine, 1917. Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):13 (Lectotype, female; Saanichton, British Columbia; Canadian Nat. Coll., 9339, designated by Bright, 1967, Canadian Ent. 99:679); Wood, 1969, Great Basin Nat. 29:116. Synonymy
Pseudohylesinus yasumatsui Nobuchi, 1971, Bull. Gov. For. Expt. Sta., Tokyo 238:160 (Holotype, male; Takanishi, Nagano, Japan; Gov. For. Expt. Sta., Tokyo); Wood, 1977, Great Basin Nat. 37:387. Synonymy
Diagnosis. - This species is distinguished from sitchensis Swaine by the broader frontal rectangle in both sexes, with the arcuate, transverse impression poorly developed, by the much stouter, discal, interstrial scales on the female, and by the more numerous, confused, interstrial crenulations at the base of the elytra. It is distinguished from nobilis Swaine by the stouter pronotal scales.

Male.- Length 2.4-3.3 mm, 2.1 times as long as wide; color dark brown, with a variegated surface pattern of pale and of dark brown scales.

Frons broadly convex above, somewhat flattened below, but not impressed on arcuate line; surface very slightly more rugose than granulatus (LeConte) or tsugae Swaine; vestiture of moderately coarse, rather short hair. Segment 1 of antennal club as long as 2 and 3 combined.
Pronotum 0.77 times as long as wide; essentially as in maculosus Blackman; scales on disc about one and one-half times as long as wide; much more slender near anterior margin.

Elytra 1.5 times as long as wide, 2.2 times as long as pronotum; outline essentially as in maculosus; striae rather narrowly impressed: punctures moderately coarse, deep; interstriae about twice as wide as striae, moderately convex, crenulations rather small, subtuberculate, at bases of 2-4 rather crowded, confused. Declivity as in maculosus except interstriae 1,3 , and 9 usually more strongly convex, 2 somewhat depressed and devoid of tubercles and bristles. Scales ovate to subcircular, each slightly longer than wide, abundant; bristles stout, half as long as distance between rows.

Female.-Similar to male except frons more strongly convex, frontal rectangle 0.95 times as long as wide; pronotal scales about two to six times as long as wide, mostly subpalmately subplumose; elytral scales one and one-half to two times as long as wide (up to four times as long as wide near suture on basal half of disc), widest at or beyond their middle, their apices broadly rounded.
Distribution. - Alaska to central California.
ALASKA: "Sitka." CANADA: British Columbia: Bear Lake near Pender Harbor, Dog Lake near Penticton. Garibaldy Park near Haney, Grouse Mt. near Yancouver, Lake Cowichan, Massett, Matacatla, Mission City, Pender Harbor, Queen Charlotte 1slands, Saanichton, Sidney, Stanley Park, Steelhead, Vancouver, Wellington. USA: California: Carson Ck. in Marin Co.. Crescent City, Duncan Mills. Facht, Ferndale, Ft. Bragg, Gasquet, Grassy Lake Humboldt Co., Inverness, Klamath, Lagunitas, Lake Pilarcitas in San Mateo Co.. Mt. Tanalpais, Noyo River in Mendocino Co., Orick, Paraiso Hot Springs, San Francisco, Santa Cruz Mits.. Warner Mts., in Modoc Co. Oregon: Alsea, Ashland, Astoria, Bear Springs, Bly, Boyer, Cannon Beach, Corvallis, Crater Lake N. P., Diamond Lake, Florence,

Glenada, Junction City, Lake of the Woods, Lost Lake, Marshfiek, Mary's Peak, McMinnville, Myrtle's Point, Otis, Pinehurst, Pistol River in Curry Co., Santiam Junction, Santiam N. F., Santiam Pass, Scio, Taft, Waldport, Willamette Pass. Washington: American Lake, Brnce Port, Chase Lake, Clear Lake, Forks, Lake Crescent, Longimire, Loveland, Mt. Rainier N. P., Nancotta, Naselle, Puget, Puyallup, Quinault, Seattle.

Hosts.-Abies amabilis, A. grandis, A. procera, Pseudotsuga menziesii, and Tsuga heterophylla.

Brology.- The somewhat variable transverse parental tumnels are cut in the limbs and bole of unthrifty, cut, or fallen trees.

Notes. - The above treatment was based on the holotypes, on my homotypes or sericeus, grandis, furnissi, and yasumatsui, and on 319 other specimens.

Confusion concerning the identity of this species resulted when the specimen, not a type, under this name in the LeConte collection was thought to be correctly determined. The LeConte specimen and the species treated as sericeus by Swaine (1917, 1918), Blackman (1942), and Bright (1969) were transferred to pini Wood (1969, 1971).

## 12. Pseudohylesimus sitchensis Swaine

Fig. 54
Psoudohylesinus sitchensis Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 141:12 Holotype, male; Menzies Bay, Vancouver Mland, British Columbia, Canadian Nat. Coll., 9342
Diagnosis.- This species is distinguished from sericeus (Mannerheim) by the less crowded basal crenulations that are almost always uniseriate to the base on interstriae 2 , 4 , and 5 , by the much more slender, nonplumose (except on extreme basal margin) setae on the female pronotum, by the more slender interstrial scales in the female, by the stronger, transverse, frontal impression, and by the narrower frontal rectangle.

Male.- Length $2.5-3.1 \mathrm{~mm}, 2.2$ times as long as wide; color as in sericeus.

Frons as in sericeus except transverse impression near middle of frons much stronger; frontal rectangle 1.20 times as long as wide.

Pronotum 0.86 times as long as wide; as in sericeus except scales about two to three times as long as wide on disc, more slender near anterior margin.

Elytra as in sericeus except crenulations at bases of interstriae 2,4 , and 5 almost always
uniseriate; scales on dise two to three times as long as wide; interstrial bristles almost as long as distance between rows.

Female.- Similar to male except frontal rectangle 1.03 times as long as wide; pronotal scales very slender, about eight or more times as long as wide, not subphumose except near basal margin; interstrial scales on dise each about four times as long as wide, widest near its base and tapered toward its apex.

Distribution.-Alaska to N California.

Fig. 53. Pseudohylesinus n. nebulosus: Antenna of female.

Fig. 54. Pseudohylesimus sitchensis: Antenna of male.

ALASKA: Afognak Isl., Junean, Prince of Wales Ist. Canadi: British Columhia: Menzies Bay, Port Renfrew. USA: California: Crescent City, Delnorte, Eureka, Klamath, Trinidad. Oregon: Camon Beach, Mt. Hood. Marshfield, Otis, Seaside. Washington: Hoquiam.

Host.- Picea sitchensis.
Biology.- The parental galleries are longitudinal and lack a nuptial chamber. The bole of cut and fallen trees is selected for attack.

Notes. - The above treatment was based on the holotype and on 79 other specimens.

## 13. Pseudohylesinus pini Wood

Pseudohylesinus pini Wood, 1969, Great Basin Nat. 29: 122 (Holotype, female; Pacific Crove, California, Wood Coll.)
Diagnosts.- This species is very similar to sitchensis Swaine, but it is distinguished by scale characters presented in the following description.

Male.- Length 2.2-2.8 mm, 2.2 times as long as wide; color dark brown with a variegated surface pattern of pale and or dark brown scales.

Frons as in sitchensis except transverse impression stronger; frontal, rectangle 1.4 times as long as wide. Pronotum as in sitchensis except scales broadly oval, each very slightly longer than wide. Elytra as in sitchensis except interstrial crenulations slightly smaller, discal scales subcircular, each about one to one and one-half times as long as wide.

Female.- Similar to male except frontal impression less well developed; frontal rectangle 1.06 times as long as wide; discal interstrial scales each one and one-half to two times as long as wide, widest at their middle, apical end rather broadly rounded.

Distribution.- British Columbia to central California.

CANADA: British Columbia: Massett; Metlaktla. USA: California: Albion, 9-VI-62, Pinus muricata; Carmel, 5-IV-25, P. radiata, F. O. Ballon; Carson Ck. in Marin Co.; Cypress Ridge in Marin Co.; Mendocino; Monterey, 2-IX-30, P. radiata; Pacific Crove, I2-N11-23, $P$. radiata: San Francisco; San Mateo; 14 miles N and 18 miles N Santa Cruz, P. radiata. Oregon: Florence, 20-VI64. P. contorta, D. E. Bright; Glenada; Lane Co., P. contorta; Newport; Sand Lake; Seaside. Washington: Westport.

Hosts.- Pinus contorta, P. muricata, and P. radiata.

Biology.- The tongitudimal parental galleries normally have a nuptial chamber. Presumably they attack the same types of host material as sitchensis.

Notes. - The above treatment was based on the type series of 4 specimens and on 46 other specimens. Prior to 1969 it was treated under the name sericeus.

## Genus HYLURGOPINUS Swaine

Hylurgopinus Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. I4(2):74 (Type-species: Hylastes rufipes Eichhoff, monohasic)
Diagnosis.- This gemus is allied to Pscudohylesinus and Dendroctonus, from which it is easily distinguished by septate sutures 1 and 2 in the antennal club, by the long, straight, transversely elevated epistomal process above the premandibular lobe, by the small size, and by many other characters.

Description.- Length $2.2-2.5 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown. Frons convex; epistomal process broad, overriding epistomal margin. Eye elongate-oval, entire. Antennal scape rather short, not reaching posterior margin of eve; funicle 7 segmented; club conate, slightly flattened, sutures 1 and 2 septate, sutures 1,2 , and 3 marked by rows of setae. Scutellum small, transversely oval. Elytral bases armed by a row of moderately high, overlapping crenulations; elytra striae conservatively sculptured. Vestiture of stout, almost scalelike ground setae and a row of erect bristles on each interstriae. Fore coxae rather widely separated; precoxal lateral ridge of prothoracic sternum obsolete. Third tarsal segments broad, somewhat bilobed. Declivital armature poorly developed.

Distribution.- One species occurs east of the Rocky Mountains in temperate North America.

Biology.- Cut or dying boles and limbs of various elms are selected for attack. The biramous parental galleries usually are transverse or primarily so; they are primarily in the phloem tissues but may engrave the wood slightly. The larval mines are also in the phloem and are exposed on peeled bark; they tend to follow the grain of the wood.

## Hylurgopinus rufipes Eichhoff

Fig. 55

Hylastes rufipes Eichhoff, 1868 (May), Berliner Ent. Zeitschr. 12:147 (Lectotype, sex?; Carolina; U.S. Nat. Mus., 53824, present designation)
Hylesinus opaculus LeConte, 1868 (September), Trans. Amer. Ent. Soc. 2:170 (Two syntypes; Pennsylvania; Mus. Comp. Zool.); Schwarz, 1896. Proc. U.S. Nat. Mus. I8:606. Synonymy

Hylurgops rufipes: LeConte, 1876, Proc. Amer. Philos. Soc. 15:390.
Hylurgopinus rufipes: Swaine, 1918, Dom. Canada Dept. Agr. Ent. Br. Tech. Bull. 14(2):74
Diagnosis.-Although not closely related, this species frequently is confused with Hy lastinus obscurus (Marsham). This species is easily distinguished from it by the long, straight, elevated epistomal process that partly overlays the epistomal margin and by the absence of an elevated ridge between each prothoracic coxa and the anterior margin of the pronotum.

Female.- Length 2.2-2.5 mm, 2.3 times as long as wide; color dark brown.

Frons convex from vertex to weak transverse impression immediately above epistomal process; epistomal process smooth, slightly elevated, straight; premandibular median epistomal lobe large, depressed below level of epistomal process, its lateral extremities overridden by or merged with epistomal process; surface smooth, shining between punctures, coarsely, very closely, rather shallowly punctured, flattened inner surface of punctures with obscure indications of reticulation; vestiture fine, short, inconspicuous, hairlike, except a conspicuous tuft along lower margin of epistomal process.

Pronotum 0.84 times as long as wide; widest toward base, sides almost parallel on basal half but weakly arcuate, narrowed, and moderately constricted just behind rather broadly rounded anterior margin; surface unarmed, smooth, shining, punctures coarse, very close, deep, interspaces not wider than half diameter of a puncture; vestiture consisting of short, semirecumbent, stout, almost scalelike setae, and slightly longer, erect bristles.

Elytra 1.5 times as long as wide, 2.0 times as long as pronotum; sides almost straight and parallel on basal two-thirds to declivital base, rather broadly rounded behind; striae slightly impressed, punctures coarse, deep; interstriae
slightly narrower than striae, convex, punctures coarse, deep; interstriae slightly narrower than striae, convex, punctures tuberculate (narrow crenulations), uniseriate except somewhat confused on basal half of 3; two or three tubercles at base of each interstriae (except l) enlarged to form small submarginal crenulations. Declivity convex, steep; striae wider than on dise, interstriae more strongly convex, with tubercles larger, pointed. Vestiture consisting of short, stout, almost scalelike setae each about five or six times as long as wide, and rows of stout erect bristles each about twice as long as ground vestiture; both types of setae extend to base.

Male.- Apparently identical to female except for differences in posterior abdominal terga.

Distribution.-SE Manitoba, S Quebec, and Maine to Kansas, Mississippi, and Alabama.

CANADA: SE Manitoba, S Ontario, S Quebec. USA: Alabama, Connecticut, Delaware, District of Columbia, Illinois, Indiana, lowa, Kansas, Kentucky, Maine, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Missouri, Nebraska, New Hampshire, New Jersey, New York, North Carolina, North Dakota, Ohio, Pennsylvania, Rhode Island, Tennessee, Vermont, Virginia, West Virginia.

Hosts.- Ulmus spp.; records also exist from Fraxinus, Prunus, and Tilia, although these attacks undoubtedly resulted from abnormal conditions.

Biology.- Cut or dying limbs or bole of the host are selected for attack. They overwinter either as larvae or adults that complete development and emerge in the spring. They emerge in May and fly to living trees, where they feed briefly before seeking a

Fig. 55. Hylurgopinus opaculus: Lateral aspect of adult; A, anterior face of left protibia; B, posterior face of left antenna. (After Kaston 1936:614.)
dying tree. The monogamous beetles construct transverse or somewhat oblique, biramous tunnels in the cambium region, scoring the wood lightly. The eggs are deposited in niches along margins of the egg galleries and the larvae radiate out from them in the general direction away from the parental tunnels and parallel to the grain of the wood. There appear to be up to two generations each year in the south, but only one in the north. This species is not aggressive in its attacks and had limited economic importance prior to the introduction of Dutch Elm disease. Since then it has been studied rather intensively.

Notes.- Because the loss of the Hamburg Museum evidently destroyed all other syntypes, the syntype labeled with a small blue paper triangle, with "rufipes, Carolina, Germar," with "no. 4," with a red "cotype" label no. " 53824 ," and with "Hylastes rufipes Eichhoff, type, = Hylastes opaculus" in the U.S. National Museum, is here designated as the lectotype of this species. In addition to the lectotype of rufipes, the two syntypes of opaculus and 321 other specimens were used to prepare the above treatment.

The priority of the name opaculus over rufipes was pointed out by Blandford (1898:5) and Wood (1979). Rabaglia and Lanier (1981), in an attempt to correct the error in priority, contributed additional confusion. The name rufipes was validated in May 1868, opaculus in September 1868.

## Genus XYLECHINUS Chapuis

Xylechinus Chapuis, 1869, Synopsis des Scolytides, p. 36 (Type-species: Hylesinus pilosus Ratzeburg. monobasic)

Diagnosis.- This genus is very closely allied to Pseudohylesinus Swaine and Xylechinosoma Schedl, but it may be distinguished by the 5 -segmented antennal funicle and by the shallowly emarginate eve; it also exhibits prothoracic precoxal ridges, although these are obscure in the North American and European species.

Description.- Length 1.5-3.5 mm, 2.0-2.4 times as long as wide; frons flat to weakly convex, sculpture simple, usually with a median carina on lower half. Eye distinctly sinuate to shallowly emarginate; elongate. Antennal scape rather short, not extending to posterior margin of eye; fumicle 5segmented: club rather small, symmetrical to slightly asymmetrical, slightly flattened, distinctly longer than wide, with three sutures marked by rows of setae. Pronotum unarmed, punctured. Scutellum small, round; elytral margins armed by one row of rather coarse crenulations; elytra striate, punctures coarse; interstriae variously punctured; declivity convex, rather simply sculptured. Vestiture consisting of an abundant ground cover of small scales and rows of longer, erect bristles. Prothoracic precoxal ridge varying from prominent to absent. Third tarsal segments bilobed.

Distribution.- Worldwide. More than 20 species have been described, about two-thirds of them from tropical America; 2 species occur in Canada and the United States, 8 species occur in Mexico and Central America.

Biology.-All the species treated here are monogamous and cut transverse, biramous, parental tumnels in the cambium region of the host tree, engraving the wood rather deeply. The larval tunnels are almost entirely in the phloem tissues, where they appear to wander at random.

## Key to the Species of Xylechinus

1. Declivital interstriae 2 narrowed, impressed, bearing a row of low tubercles on its lateral side, and devoid of row of bristles; Guatemala; 3.0 mm 1. scabiosus Blandford

- Declivital interstriae 2 similar to 1 and 3, usually bearing similar bristles .................. 2

2(1). Base of discal interstriae 2 to 5 each bearing two or more submarginal crenulations; row of elytral bristles of setae not longer than distance between rows; Costa Rica; Oreopanax nubigenus: $2.4-3.3 \mathrm{~mm}$ 2. avarus Wood

- Discal interstriae devoid of submarginal crenulations; either elytral bristles considerably longer than distance between rows or body shorter than 2.0 mm

3(2). Striae at least as wide as interstriae, punctures very deep, close; erect interstrial bristles spaced within each row by distances averaging about equal to length of a bristle; Canada and the United States; in Picea; 2.3-2.7 mm

- Striae not wider than interstriae, punctures rather small, not strongly impressed or close; erect interstrial bristles spaced within each row by distances averaging two or more times length of a bristle; tropical species in Oreopanax 5

4(3). Discal interstriae as wide as striae, strial punctures distinctly smaller; erect interstrial bristles more slender, about 8 to 10 times as long as wide; Ontario to Maine; Picca glauca; 2.3-2.4 mm
3. americanus Blackman

- Discal interstriae distinctly narrower than striae, strial punctures very coarse; erect interstrial bristles stout, about four to six times as long as wide; Picea engelmannii; Alaska and Saskatchewan to California and New Mexico; $2.3-2.7 \mathrm{~mm}$

4. montanus Blackman

5(3). Erect elytral bristles much longer, equal in length to twice width of interstriae, distance between bristles within a row often two to four times width of interstriae; striae more narrowly, deeply impressed; patches of dark and light scales about equal

- Elytral bristles shorter, usually not longer than distance equal to width of one interstriae, spaced within a row by one to two times this distance; striae more feebly impressed, wider; dark and light patches less definite, light scales usually predominant
6(5). Size much larger; erect elytral bristles much longer, finer, and much more closely spaced; sides of pronotum on anterior half strongly, arcuately constricted; longer pronotal setae slender, almost hairlike; Guatemala; $3.2 \mathrm{~mm} . . . .$.

5. irrasus Blandford

- $\quad$ Size smaller; erect elytral bristles stouter, more widely spaced, none longer than twice distance between rows; longer pronotal setae short, stout; Oaxaca to Guatemala; $1.7-2.0 \mathrm{~mm}$

6. tessallatus Blandford

7(5). Larger; striae distinctly narrower than interstriae; declivital bristles a little more slender and distinctly shorter than distance between rows of bristles; Costa Rica and Panama; 1.9-2.2 mm
7. fuliginosus Blandford

- Smaller; striae wider, almost as wide as interstriae; declivital bristles coarser, fully as long as distance between rows of bristles
8(7). Pronotum with some scalelike setae; pronotum stouter, more regularly sculptured; interstrial bristles stouter, slightly shorter; strial punctures smaller; Guatemala; 1.5-1.8 mm

8. marmoratus Blandford

- Pronotum without scalelike setae; pronotum more slender, more irregularly sculptured; interstrial bristles longer, more slender; strial punctures larger; Chiapas; $1.6-1.9 \mathrm{~mm}$ 9. mexicanus Wood

## 1. Xylechinus scabiosus Blandford

Xylechinus scabiosus Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):158 (Lectotype, female; Volcán de Agua, $8500-10,500 \mathrm{ft}$. Guatemala; British Mus. Nat. Hist., present designation)
Diagnosis.- This species is distinguished from irrasus Blandford by the more strongly impressed declivital interstriae 2, which has on its lateral half a series of about 10 closely
set, rounded tubercles, by the reticulate surface of the elytral declivity, and by the much shorter vestiture.

Female.- Length $3.0 \mathrm{~mm}, 2.0$ times as long as wide; color very dark brown, with an indistinct pattern of dark and light scales.

Frons convex above, flattened to slightly impressed on lower two-thirds, a sharply elevated, low median carina on impressed
area; surface minutely granulate, small punctures obscurely indicated; vestiture hairlike, fine, sparse, moderately long.

Pronotum 0.86 times as long as wide; widest slightly in front of middle, sides on posterior half very feebly arcuate, abruptly rounded in front, then constricted just before rather narrowly rounded anterior margin; surface evidently rather coarsely, deeply, closely punctured, obscured by rather abundant scales (encrusted, character of scales not clear).

Elytra 1.35 times as long as wide, 2.0 times as long as pronotum; sides almost straight and parallel on basal two-thirds, narrowly rounded behind; basal margins each armed by about 12 small crenulations, submarginal crenulations evidently absent; striae weakly impressed, punctures coarse, deep; interstriae as wide as striae, evidently slightly irregular but not granulate (obscured by an incrustation). Declivity steep, convex; striae about as on disc; interstriae 1 moderately and 3 slightly elevated, 2 narrowed, impressed, its lateral margins rather coarsely granulate, about 10 low, rounded granules present, 9 moderately elevated on posterior half. Vestiture of abundant, short scales (encrusted) and interstrial rows of longer bristles, each bristle about equal in length to distance between rows, closer within a row; bristles absent on declivital interstriae 2.

Distribution.-Guatemala.
GUATEMALA: Volcán de Agua, $8500-10,500 \mathrm{ft}$, by G. C. Champion.

Notes.- The first female in Blandford's series of four female syntypes has been regarded as the type. It was used to prepare the above description and it is here designated as the lectotype for this species.

## 2. Xylechinus avarus Wood

Xylechinus avarus Wood, 1968, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):1 (Holotype, female; Volcán Irazu, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- Of the species known to me, this one is perhaps more closely allied to $f u$ liginosus Blandford, although the relationship is remote. The large body size, the stout form, the submarginal crenulations on the
elytral bases, the elevated declivital interstriae 1 and 3 , and the fine, low, frontal carina serve to distinguish this species.

Female.- Length $2.4-3.3 \mathrm{~mm}, 2.1$ times as long as wide; body color brown, usually covered by an incrustation.

Frons convex, with a feeble, transverse impression just below upper level of eyes, a low, acutely elevated, median carina extending from this impression to epistomal margin; entire surface coarsely reticulate, punctures fine, inconspicuous; vestiture short, sparse, inconspicuous.

Pronotum 0.93 times as long as wide; sides widest and almost parallel on middle half, strongly constricted one-fourth length from anterior margin, rather broadly rounded in front; surface finely granulate and with rather sparse, round, small, vulcanate punctures; vestiture consisting of short, rather stout, moderately abundant bristles.

Elytra 1.2 times as long as wide, 1.8 times as long as pronotum; sides almost straight, very slightly wider at declivital base, narrowly rounded behind; striae impressed, punctures deeply, not sharply impressed; interstriae about one and one-half times as wide as striae, irregular, punctures fine, abundant, confused, with a median row of larger, marginally granulate punctures, crenulate toward base on interstriae 1 to 5 . Declivity convex, rather steep; striae impressed; interstriae 2 impressed, strongly narrowed, ending before apex, 1,3 , and 9 elevated, about half as high as wide, 3 and 9 join apically, the elevation continued to 1 ; granules not as large as on disc. Vestiture of short, rather abundant, stout setae, and interstrial rows of long bristles, spacing between bristles within a row and between rows equal to length of a bristle.

Male. - Similar to female except frons flattened on lower half, and ground vestiture of pronotum and elytra evidently more abundant.

Distribution.- Costa Rica.
COSTA RICA: Volcán Irazu, Cartago, 26-X-63. 2300 m, Oreopanax nubigenus, S. L. Wood.

Biology.- Specimens were taken from biramous, transverse, parental galleries in limbs $7-20 \mathrm{~cm}$ in diameter in a host that was parasitic on a felled oak tree. Larval mines were not fully developed.

Notes. - The type series of 207 specimens was available for preparing the above treatment.

## 3. Xylechinus americanus Blackman

Xylechinus americants Blackman, 1922, New York st. Coll. For. Tech. Pul. 16:117 (Holotype, make: Orono, Mane: U.S. Nat. Mus., 26(io30)
Diagnosis. This species is distinguished from the very closely allied pilosus (Ratzeburg) by the more strongly impressed, much wider striae.

Female.- Length 2.3-2.4 mm, 2.5 times as long as wide; color medimm to dark brown, pronotum slightly darker.

Frons convex, transversely impressed just above epistoma; epistomal margin slightly elevated, epistomal lobe small: surface finely. sulbramulately punctured, a fine median carina extending from just below upper level of eves to base of epistomal lobe; vestiture hairlike, short, moderately ahundant, longer and more conspicuous toward epistoma.

Pronotum l.0.4 times as long as wide: widest at base, sides weakly arcuate and converging slightly on posterior two-thirds to a prominent constriction, rather broadly rounded in front; surface rather finely, closely punctured, narrow interspaces smooth, with a few points; vestiture covering entire surface, consisting of short, rather slender scales, rather abundant.

Elytra 1.7 times as long as wide, 2.0 times as long as pronotum; sides almost straight and parallel on basal two-thirds to base of dectivity then marrowly romnded behind: cremulations at elytral bases narrow and high, submarginal crenulations ahmost totally absent; striae slightly impressed, punctures rather coarse, deep; interstriae convex, as wide as striae except slightly wider at base of declivity, punctures moderately small, gramulate on anterior margin, in irregular median rows, with small, supplemental, simple punctures along margins. Declivity convex, moderately steep; striae deeper and narrower than on dise: interstriae 1, 3, and 9 verv weakly elevated. Vestiture consisting of rather abundant, short, narrow, almost scalelike, interstrial setae, and median rows of erect, stont bristles, each bristle abont twice as long as scales and six to eight times as long as wide.

Male. - Similar to female except frons less convex, almost flat on median half.

Distribution.- Ontario to Maine.
CANADA: Ontario: "Near" Ottawa. Quebec: Chelsea, 17-V-5t. Picea glanca, S. L. Wood; Great Whate River, 30-V1-49, J. R. Vockeroth. USA: Maine: Camp Caribou, Hopk. L'S. 332a. Piceu; Orono, 13-X゙-19, M-171, P. glauca, M. W. Blackman. New York: Cranberry Lake, 1T-11I-21, M. W. Blackman.

## Hosts.- Picea glauca.

Biology.- Usually small, smppressed, shaded out, standing trees less than 15 cm in diameter are selected for attack. The attacks most commonly are within l m of the ground. Occasionally they attack shaded out branches of dominant trees. The habits basically are as outlined above under the generic treatment.

Notes. - The above treatment of the female was based largely on Blackman's

Fig. 56. .Vylechimus montanus: Dorsal aspect. (After Bright 1976:206.)
allotype, the male was based on the holotype; 81 other specimens were also studied.

## 4. Xylechinus montanus Blackman

 Fig. 56Xylechinus montanus Blackman, 1940, Proc. Ent. Soc. Washington 42:123 (Holotype, temale; Sula. Montana; U.S. Nat. Mus., $54(124)$
Diagnosis.- This species is distinguished from americanus Blackman as indicated in the above key and in the description.

Female.- Length 2.3-2.7 mm, 2.5 times as long as wide.

Frons and pronotum as in americanus except in most specimens punctures not as close, their interspaces obscurely reticulate to minutely rugose.

Elytra as in americanus except strial punctures distinctly larger, interstriae distinctly narrower than striae, about half to two-thirds as wide; interstrial ground vestiture less abundant; erect interstrial bristles much stouter, each about four to six times as long as wide.

Male.- Similar to female except frons less distinctly convex, almost flat on median half.
Distribution.- Alaska and Saskatchewan to California and New Mexico.

ALASKA: Kenai Peninsula, 14-21-V1-74, M. M. Furniss. CANADA: Alberta: Banff, Waterton. British Columbia: Lorna. Saskatchewan: Cypress Hills. USA: Colorado: Cross Creek in Rio Grande N. F., Dolores Peak in Uncompahgra N. F., Newcastle. Montana: Anaconda, Blackfeet N. F., Columbia Falls, Nevada: Charleston Mt. Oregon: Gold Lake in Willamette N. F., Suttle Lake, Toll Gate. Utah: Logan Canyon.

Host.- Picea engelmannii.
Biology. - As in americanus.
Notes.- The above treatment was based on the holotype and on 117 other specimens.

## 5. Xylechinus irrasus Blandford

Xylechinus irrasus Blandford, 1897. Biol. Centr. Amer., Coleopt. 4(6):157 Lectotype, male; Volcán de Agua, $850(0)-10.500 \mathrm{ft}$. Guatemala: British Mus. Nat. Hist., present designation)
Diagnosis.- This species is distinguished from scabiosus Blandford by the less strongly impressed declivital interstriae 2 which has not more than three or four minute, widely spaced tubercles, by the smooth, declivital surface, and by the much longer vestiture.

Male.- Length $3.2 \mathrm{~mm}, 2.1$ times as long as wide; color dark brown, with a variegated pattern of light and dark setae.

Frons broadly impressed from epistoma to level of antennal insertion, then broadly concave to upper level of eyes; epistomal lohe large, flat; median carina on lower half acute, obsolete above, a pair of lateral calluses just above level of antennal insertion; surface reticulate, becoming granulose above, with fine, sparse punctures; vestiture of long, coarse bristles laterally, shorter in other areas.

Pronotum 0.77 times as long as wide; widest near middle, sides diverge rather strongly from base, rather strongly arcuate in front of middle and converging to constriction just before rather broadly anterior margin; surface at least partly shining, punctures close, rather fine, at least some of those in summit area feebly vulcanate; median line acutely elevated in area of indefinite summit; vestiture of rather abundant, moderately short bristles (almost scalelike) and must less abundant, very long bristles, each up to five times as long as ground setae.

Elytra 1.4 times as long as wide, 2.4 times as long as pronotum; sides somewhat straight and parallel on basal two-thirds, rather narrowly rounded behind; basal margins each armed by about 10 small crenulations, submarginal crenulations absent; striae weakly impressed toward declivity, punctures moderately coarse, deep; interstriae slightly wider than striae, weakly convex at least posteriorly, punctures close, confused, mostly very fine, a few larger punctures intermixed, none granulate. Declivity steep, convex; strial punctures deeper; interstriae more nearly convex, 2 not as high as 1 or 3, all devoid of granules. Vestiture consisting of rather abundant, short, scalelike bristles and less abundant, very long, interstrial bristles, long bristles in indefinite rows, up to twice as long as distance between rows, separated within a row by about half that distance.

Distribution.-Guatemala.
GUATEMALA: Volcan de Agua, between 5500 and 10.500 ft elevation, by G. C. Champion.

Notes. - The above description was prepared from the male of Blandford's two syntypes. It is here designated as the lectotype for this species.

## 6. Xylechinus tessellatus Blandford

Xylechinus tessallatus Blandford, 1897. Biol. Centr. Amer., Coleopt. 46:15.9 Holotype, female;

Volcán de Agua, Guatemala; British Mus. Nat. Hist.)
Diagnosis.- This species is of the same general size and sculpture as fuliginosus Blandford, but it is distinguished by the much longer, more widely spaced erect, elytral bristles, and by other characters mentioned in the above key.

Female.- Length $1.7-2.0 \mathrm{~mm}, 2.1$ times as long as wide; body color dark brown, with a dense mottled covering of dark and light scales, dark and light areas almost equal in extent.

Frons convex with a weak, transverse impression immediately above level of ocular emargination; narrowly, transversely impressed just above the weakly elevated epistomal margin; epistomal lobe large; an acutely elevated carina extending from midfrontal impression to base of epistomal lobe; surface coarsely reticulate, with a few fine punctures on lower third toward margins, a few fine granules toward center; vestiture fine, inconspicuous.

Pronotum 0.88 times as long as wide; widest at middle, sides on basal half almost straight, diverging very slightly to middle then strongly arcuate to rather strong constriction just behind very broadly rounded anterior margin; surface finely, closely punctured, obscured by scales; vestiture consisting of scales of two sizes, smaller ones more abundant, very short, rather narrow, larger ones but little longer at base, becoming two or more times as long anteriorly.

Elytra 1.4 times as long as wide, 2.0 times as long as pronotum; sides almost straight and parallel on basal two-thirds to declivital base, rather narrowly rounded behind; striae narrowly, rather strongly impressed, punctures small, somewhat obscure; interstriae twice as wide as striae, convex, closely covered by squamiferous punctures. Declivity convex, steep; interstriae l-3 equally convex, 9 more strongly elevated, angle between 3 and 9 somewhat impressed, granules not evident. Vestiture consisting of abundant small scales and interstrial rows of erect bristles to base; bristles widely spaced, mostly spaced at least by three or more times distance between rows, bristles on declivity mostly one and one-half to two times as long as distance between rows, except slightly shorter on interstriae 2.

Male.-Similar to female except lower half of frons flat, transverse impression somewhat stronger.

Distribution.- Oaxaca to Guatemala.
MEXICO: Chiapas: Mt. Tzontehuitz, 19-V-69, J. M. Campbell. Oaxaca: 83 km N Oaxaca, 17-V-71, D. E. Bright; 64 km S Valle Nacional, 25-V-71, H. F. Howden. GUATEMALA: Volcán Zunil, Quezaltenango, 27-V-64, 1000 m , Orcopanax, S. L. Wood; Volcán de Agua, G. C. Champion.

Biology.- The small, terminal branches of living host trees were attacked. Often these branches would break and fall to the ground and, although appearing largely decayed, sometimes contained large numbers of specimens. The galleries were as described above under the generic treatment.

Notes.- The unique type was examined and compared directly to my Volcán Zunil homotypes. The above treatment was prepared from the four homotypes and 74 other specimens.

The original description gives the length of the type as 2.3 mm ; actually it is 2.0 mm long.

## 7. Xylechinus fuliginosus Blandford

Xylechinus fuliginosus Blandford, 1897, Biol. Centr.Amer., Coleopt. 4(6):158 (Holotype, female; Volcán de Chiriquí, Panama; British Mus. Nat. Hist.)
Diagnosis.- Characters summarized in the above key distinguish this species from allied forms.

Female.- Length 1.9-2.2 mm, 2.1 times as long as wide; color dark brown, with abundant dark and light scales, dark scales usually predominating.

Frons as in tessallatus. Pronotum as in marmoratus except stout scales almost twice as long as small ones, only slightly longer anteriorly.

Elytra 1.4 times as long as wide, 1.9 times as long as pronotum; outline as in marmoratus; striae moderately impressed, punctures small, rather obscure; interstriae about twice as wide as striae, punctures small, confused, some of median ones granulate toward base. Declivity as in marmoratus except interstriae less strongly elevated or convex. Vestiture consisting of abundant small scales and interstrial rows of erect, rather slender bristles to base; each declivital bristle as long as distance between rows and separated within rows by about twice this distance.

Male- Similar to female except frons flattened on lower half.
Distribution.- Costa Rica and Panama.
COSTA RICA: Volcán Irazu, Cortago. 28-VI-63, 2.800 m , and $26-\mathrm{IN}-63,2300 \mathrm{~m}$, Oreopanax xalapense, S . L. Wood. PANAMA: Volcán de Chiriquí, G. C. Champion; Cerro Punta, Chiriqu. 1, 11-I-64, 1800 m , Oreopanax, S. L. Wood.

Host.- Oreopanax xalapense.
Biology.- Terminals of shaded-out branches on standing trees or cut branches up to about 10 cm in diameter were attacked. The gallery systems were as described above for the genus.

Notes.- The unique holotype was compared directly to 2 of my homotypes; from these 2 and 96 other specimens the above treatment was prepared.

## 8. Xylechinus marmoratus Blandford

Xylechinus marmoratus Blandford, 1897, Biol Centr. Amer., Coleopt. $4(6): 159$ (Lectotype, female; Capetillo, Guatemala: British Mus. Nat. Hist., present designation)
Diagnosis.- This is the smallest Central American representative of the genus; it is also the one most closely allied to americanus. It may be distinguished by its small size and by other characters mentioned in the above key.

Female.- Length $1.5-1.8 \mathrm{~mm}, 2.4$ times as long as wide; color dark brown, with abundant dark and light scales, dark ones usually predominate.

Frons weakly convex, with a rather prominent transverse impression just above the slightly elevated epistomal margin; epistomal lobe well developed; surface minutely granulate above, with fine punctures; vestiture of short coarse bristles.

Pronotum 0.98 times as long as wide; outline and sculpture as in tessellatus except posterior half of sides more nearly arcuate; vestiture but little longer anteriorly, abundant, consisting of slender and stout bristlelike scales, stout ones only slightly longer.

Elytra 1.5 times as long as wide, 1.9 times as long as pronotum; outline as in tessellatus; striae weakly impressed, punctures rather coarse, deep; interstriae almost one and onehalf times as wide as striae, rather weakly convex, punctures fine, squamiferous. Declivity convex, moderately steep; interstriae 1,3 , and 9 weakly elevated, 2 feebly impressed.

Vestiture consisting of abundant small scales and interstrial rows of erect, stout bristles to base; each bristle as long as distance between rows, separated within rows by twice that distance.

Male.-Similar to female except lower half of frons flattened.

Distribution.-Guatemala.
GUatemala: Volcán de Agua, 19-V-64, $1,000 \mathrm{~m}$, Oreopanax, S. L. Wood; Volcán Pacaya, 1-VI-64, 1300 m, Oreopanax, S. L. Wood; Panajachel, Sololá, G. C. Champion.

Hosts.- Oreopanax spp.
Biology.- Small, shaded out branches are selected for attack. The habits appeared to be as described in the above treatment of the genus.

Notes.- Blandford's series of four syntypes and 44 other specimens were used to prepare the above treatment. From Blandford's four syntypes a female from Capetillo was selected and is here designated as the lectotype of the species.

## 9. Xylechinus mexicanus Wood

Xylechinus mexicanus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):7 (Holotype, male; Yerba Buena, 32 km or 20 miles N Bochil. Chiapas, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from marmoratus Blandford by the more slender, more irregularly sculptured pronotum that lacks scalelike setae, by the slightly coarser strial punctures, and by the much more slender interstrial bristles.

Male.- Length $1.6-1.9 \mathrm{~mm}, 2.7$ times as long as wide; color brown, vestiture pale.

Frons as in marmoratus but broader, vestiture finer, without scales.

Pronotum 1.0 times as long as wide; about as in marmoratus but anterior constriction not as strong; surface shining, irregular throughout, punctures fine, shallow, most subvulcanate. Vestiture of short, coarse hair of moderate abundance; scales absent.

Elytra 1.7 times as long as wide; as in marmoratus except bases of interstriae 2-5 each bearing 1-4 submarginal crenulations, strial punctures very slightly larger. Ground vestiture shorter than in marmoratus, apparently less abundant, much more slender on sutural interstriae than elsewhere; erect bristles slender, blunt or pointed, their length and spacing as in marmoratus.

Female.- Similar to male except submarginal crenulations at bases of elytra mostly absent.

Distribution.-Chiapas.
MEXICO: Chiapas: Yerba Buena 32 km or 20 mi N Bochil, 2l-V-69, $2600 \mathrm{~m}, \mathrm{D}$. E. Bright.

Notes.- The above treatment was based on the type series of seven specimens.

Genus DENDROCTONUS Erichson

Dendroctonus Erichson, 1836, Archiv Naturgesch. 2(1):52 (Type-species: Bostrichus micans Kugelann, subsequent fixation by the International Commission on Zoological Nomenclature, 1963:276)
Diagnosis. - This genus is related to $H y$ lurgus Latreille and Tomicus Latreille, of Europe and Asia, to Pachycotes Sharp, of Australia and New Zealand, and to Hylurgonotus Schedl, of South America, but it may be distinguished by the 5 -segmented antennal funicle, by the unique epistomal process, by the total absence of a male frontal impression, and by the more strongly flattened antennal club. Among North and Central American genera it is related to Pseudohylesinus Swaine and Hylurgopinus Swaine, but may be easily distinguished by characters summarized in the above key to genera.

Description.-Length $2.5-9.0 \mathrm{~mm}$, 2.3-2.6 times as long as wide; body color dark brown to black, some species with reddish brown elytra. Frons convex, usually modified by grooves, elevations, or tubercles; sexual dimorphism pronounced in some species. Eye ovate, entire. Antennal scape rather long; funicle 5 -segmented; club rather strongly flattened, subcircular in outline, three weakly procurved, aseptate sutures indicated by setae. Pronotum wider than long, unarmed, punctate. Scutellum small. Elytra more than twice as long as pronotum, basal margins armed; striate, interstriae variously crenulate; declivity steep, variously, conservatively sculptured, sexually dimorphic in some species. Vestiture hairlike. Fore coxae contiguous; precoxal prothoracic ridges absent. Third tarsal segments bilobed.

Distribution.- Arctic North America to northwestern Nicaragua ( 16 species), northern Europe and Asia (2 species).

Biology.- These monogamous beetles breed in coniferous hosts larger than six
inches in diameter. Collectively they are the most destructive natural biological agent in American coniferous forests. Most species breed only in standing trees, although endemic populations of rufipennis (Kirby) and murrayanae Hopkins may breed in prostrate trees. All species, with the possible exception of approximatus Dietz, are capable of killing healthy, vigorous trees.

The entrance tunnel is formed by the female; the male joins her when the tunnel is about $1-7 \mathrm{~cm}$ long. The attraction of the male and of other females to the host tree is by pheromones released by the female. The egg galleries may be either sinuate or longitudinal and are characteristic of the species. Eggs are deposited individually in niches, in small clusters, or in rows in long grooves. The larval mines of most species are individual and radiate from the parental mine, or the larvae may feed in congress for part or all of their development. They pupate in individual cells and emerge through separate exit holes. The length of the life cycle varies within the genus; ordinarily it occupies one year, but in arctic regions it may be extended to two or more years, or in tropical areas be shortened to as little as three or four months in certain species.

Apparently all species are associated with symbiotic fungi that modify host physiology and greatly accelerate the rate at which host resistance to attack can be overcome. It is this factor that has made them so tremendously successful as agents of destruction.

Notes.- Since my previous treatment of this genus (Wood 1963), a great deal of information pertaining to it has accumulated. Pheromone and karyology studies have been made, the types of rufipennis and parallelocollis were located, all types in the genus except terebrans (Olivier) were reexamined, and additional field data of taxonomic significance has been gathered. This has resulted in a number of modifications presented below, including the removal of jeffreyi Hopkins and mexicanus Hopkins from synonymy.

The Chinese armandi Tsai and Li was omitted from the following key; it is a unique species very different from the remainder of the genus that compromises characters of species in couplets 14 to 16 of the key.
(Modified from Wood 1963)

1. Frons with a rather deep, narrow, median groove extending from just above epistomal process to upper level of eyes; if median impression obscure in male, then lateral areas of frons rather strongly protuberant and usually armed by one or two tubercles (except adjunctus); if protuberance obscure in female, then anterior constriction of pronotum with a transverse elevated callus laterally and dorsally (obscure laterally in adjunctus); epistomal process very broad with the lateral margins prominently raised; smaller species $2.5-7.4 \mathrm{~mm}$, in Pinus

- Frons without a median groove or impression below upper level of eyes; lateral elevations of frons and transverse elevated callus of pronotum never present in either sex; epistomal process usually narrower and less prominent, lateral margins raised or not; larger species $5.0-9.0 \mathrm{~mm}$ (rarely as small as 3.7 , or even 3.4 in simplex), in Pinus and other conifers7

2(1). Punctures and/or granules of declivital interstriae 2 more abundant, confused; declivital interstriae 2 as wide as 1 and 3, not constricted apically; smaller species, 2.5-5.0 mm3

- Granules of declivital interstriae 2 rather sparse, uniseriate; declivital interstriae 2 narrower than 1 and 3 or strongly constricted apically; larger species, $3.8-7.4 \mathrm{~mm}$

3(2). Declivital pubescence rather abundant and uniformly short, not longer than a distance equal to half width of an interstriae; transverse discal rugae on posterior half of discal interstriae almost never longer than half width of an interstriae; declivital striae usually not impressed, obscure; punctures of declivital interstriae more abundant and feebly if at all granulate; British Columbia to Chihuahua and W Texas; Pinus ponderosa, P. coulteri; 2.5-5.0 mm

1. brevicomis LeConte

- Declivital pubescence less abundant, at least some hairs twice as long as width of an interstriae; at least a few rugae on posterior half of elytral disc as wide as an interstriae; declivital striae usually impressed, punctures larger and distinct from those of interstriae; punctures of declivital interstriae less abundant and more coarsely granulate 4

4(3). Lateral thirds of pronotum with punctures finer, closer, their diameters rarely equal to more than twice diameter of a facet of eye, usually with several tubercles, posterolateral areas with at least one-third of area granular, granulation often obliterating punctures; male epistomal process wider, its lateral arms more strongly elevated; male frontal tubercles less numerous, smaller; elytral crenulations, particularly on declivity, smaller; mature color almost black; Guatemala; $2.6-4.6 \mathrm{~mm}$

- Lateral thirds of pronotum with punctures larger, not as close, some punctures equal in diameter to at least three times diameter of facet of eye, tubercles and granulation inconspicuous or absent; male epistomal process slightly narrower; male frontal tubercles more numerous, larger; elytral crenulations averaging larger; mature color dark brown; smaller species

5(4). Female frons more finely punctured, area immediately above epistomal process flat, male arms of epistomal process less strongly elevated; strial grooves on dise usually wider, strial punctures larger and without crenulate tubercles
between strial punctures; interstrial crenulations averaging smaller and less numerous; mature color light brown to medium brown; Oklahoma and Pennsylvania to Arizona, New Mexico, E Texas, Florida, and Honduras; inus; 2.2-3.2 mm
3. frontalis Zimmermann

- Female frons more coarsely punctured, area immediately above epistomal process concave (due to elevation of lateral arms), male arms of epistomal process more strongly elevated; strial grooves on disc usually narrower, punctures usually smaller or obsolete, their anterior margins finely crenulate; interstrial crenulations usually averaging larger; mature color medium brown to black; Chihuahua to Honduras; Pinus; 2.4-3.7 mm

4. mexicanus Hopkins
$6(2)$. Granules on declivital interstriae 1 and (usually) 3 more abundant, confused; transverse elevation of female pronotum very prominent laterally; male frons with prominent lateral tubercles; stouter, 2.5 times as long as wide; central Utah and Colorado to Honduras; Pinus; 4.5-7.4 mm
5. approximatus Dietz

- Granules on declivital interstriae 1 and 3 sparse, uniseriate; transverse callus on female pronotum obscure laterally; male frons without lateral tubercles; more slender, 2.65 times as long as wide; central Utah and Colorado to Guatemala; $3.8-6.0 \mathrm{~mm}$

6. adjunctus Blandford

7(1). Declivital interstriae dull (minutely rugulose) or shining, if shining punctures virtually all granulate in both sexes and strial punctures distinct and larger; epistomal process rather broad, distance between eyes not more than 2.2 times its basal width; episternal area of prothorax more coarsely granulate; punctures obscure or absent 8

- Declivital interstriae smooth and shining, most punctures impressed, a few of them granulate in female; epistomal process rather narrow, distance between eyes three or more times its basal width; episternal area of prothorax punctate, granules minute or entirely absent 12
8(7). Surface of declivity dull (usually rugulose); declivital interstriae 2 impressed, usually flat, interstriae 1 strongly and 3 weakly elevated; declivital interstriae usually uniseriately granulate and with scattered fine punctures9
- Surface of declivity usually shining, interstriae 2 not impressed and sutural interstriae weakly if at all elevated; virtually all of rather numerous punctures on declivital interstriae granulate, granules close, confused
$9(8)$. Punctures on pronotum rather coarse, close, separated by distances averaging less than diameter of a puncture, inner floor of a puncture usually flat or bearing a granule; California specimens averaging conspicuously smaller, 96 percent of them smaller than 5.0 mm ; S British Columbia and W South Dakota to Baja California and New Mexico; Pinus; 3.7-7.5 mm

7. ponderosae Hopkins

- Punctures on pronotum usually minute, separated by distances averaging at least twice diameter of a puncture, inner floor of puncture usually concave and without a granule; S Oregon to Baja California; Pinus jeffreyi; $5.0-7.5 \mathrm{~mm}(6$ percent are smaller than 5.0 mm )
10(8). Epistomal process broad, flat, its margins not elevated; strial punctures rather small and obscure, rugae of discal interstriae very coarse, many as wide as interstriae, a few crossing striae; frons strongly, evenly convex; pronotum gradually narrowed anteriorly, without an abrupt constriction; Chihuahua and Sinaloa to Honduras; Pinus; $5.2-6.9 \mathrm{~mm}$

9. parallelocollis Chapuis

- Epistomal process broad, transversely concave, margins strongly elevated; strial punctures larger, never traversed by smaller discal rugae; frons irregularly, less strongly convex; pronotum feebly if at all narrowed anteriorly, with an abrupt constriction just behind anterior margin

11(10). Body color of mature specimens black; punctures on dise of pronotum rather coarse, those near lateral margin much larger; declivital tubercles usually larger, apparently more numerous; E Massachusetts to E Texas and Florida; Pinus; $5.0-8.0 \mathrm{~mm}$
10. terebrans (Olivier)

- Body color of mature specimens reddish brown; punctures of pronotum not as coarse, those near lateral margin similar to those on disc; declivital tubercles usually smaller, apparently less numerous; Northwest Territories and Nova Scotia to Honduras; Pinus, rarely other conifers; $5.4-9.0 \mathrm{~mm}$ (see also 12. rhizophagus Thomas \& Bright)

12(7). Declivital striae weakly if at all impressed, 2 apically curved toward sutural striae; declivital interstriae 1 feebly elevated, 2 as wide or wider than 1 or 3 (except near apex); discal striae less than half as wide as interstriae; epistomal process usually transversely concave (except micans), rather broad, lateral margins moderately oblique (less than 55 degrees from horizontal)

- Declivital striae strongly impressed, 2 straight; declivital interstriae I strongly elevated, 2 weakly impressed and narrower than 1 or 3 ; discal striae almost as wide as interstriae; epistomal process flat or convex, narrow, its lateral margins strongly oblique (about 80 degrees from horizontal)16

13(12). Frons smooth and polished, with deep close punctures, but almost entirely without granules between punctures; strial punctures on declivity rather large, three or more times as large as those of interstriae14

- Frons rather finely granulate between close, deep punctures (granules sometimes obscure in murrayanae); strial punctures on declivity usually minute, seldom more than twice as large as those of interstriae15

14(13). Epistomal process flat; body stouter, 2.3 times as long as wide; strial punctures more strongly impressed; northern Europe and Asia; 6.0-8.0 mm
micans (Kugelann)

- Epistomal process shallowly, transversely concave; more slender, 2.4 times as long as wide; strial punctures shallowly impressed; Alaska and Alberta to New York and West Virginia; Picea; 5.4-6.5 mm 13. punctatus LeConte

15(13). Frons coarsely, distinctly punctured, granules between punctures usually isolated from one another, often very sparse; male genitalia distinctive; British Columbia and Ontario to Utah, Colorado, and Michigan; Pinus banksiana, P. contorta; $5.0-7.3 \mathrm{~mm}$
14. murrayanae Hopkins

- $\quad$ Frons very closely, more coarsely granulate, punctures usually obscure in central area; male genitalia distinctive; Alaska and Newfoundland to Arizona, New Mexico, and Pennsylvania; Picea; 4.4-7.0 mm

16(12). Frons moderately protuberant, smooth, with rather coarse, deep punctures; punctures of pronotum rather large; discal interstriae with fine punctures interspersed with small rugae; Alaska and NE British Columbia to Newfoundland and West Virginia; Larix; smaller, 3.4-5.0 mm
16. simplex LeConte

- Frons strongly protuberant, irregular, granulate, with rather fine, deep punctures; punctures of pronotum rather small; discal interstriae without fine punctures dispersed among rugae; S British Columbia and SW Alberta to California and Chihuahua; Pseudotsuga, Larix; 4.7-7.0 mm

17. pseudotsugae Hopkins

## 1. Dendroctonus brevicomis LeConte

 Figs. 1, 3, 4, 57, 58Dendroctonus brevicomis LeConte, 1876, Proc. Amer. Philos. Soc. 15:386 (Holotype, female; middle California; Mus. Comp. Zool.)
Dendroctonus barberi Hopkins, 1909, U.S. Dept. Agric. Bur. Ent. Tech. Bull. 17(1):85 (Holotype, female; Williams, Arizona; U.S. Nat. Mus., 7444); Wood, 1963, Great Basin Nat. 23:31. Synonymy
Diagnosis.- This species is distinguished from the closely related frontalis Zimmermann by the uniformly short declivital pubescence, by the less strongly impressed declivital striae, by the more numerous, more finely granulate punctures of the declivital interstriae, by the larger average size, and, in part, by the distribution.

Male.- Length 2.0-4.7 mm (average about 3.5 mm ), 2.2 times as long as wide; mature color very dark brown.

Frons convex, a pair of lateral elevations on median half just below upper level of eyes separated by a deep median groove, summits of elevations armed at their dorsomedian margins by one or two prominent, somewhat dorsomedially oriented granules; epistomal margin elevated, its surface smooth and shining; epistomal process half ( 0.50 times) as wide as distance between eyes, its arms oblique (about 40 degrees from horizontal) and elevated, horizontal portion about half its total width, transversely concave, overlapping and ending just above epistomal mar gin and bearing under its distal margin a dense brush of conspicuous yellowish setae; surface granulate-punctate above eyes, more deeply punctured and subgranulate below. Vestiture, except epistomal brush, short, sparse, inconspicuous.

Fig. 57. Dendroctonus brevicomis: A, male head; B, female head; C, elytral declivity; D, male genital capsule; E, male seminal rod; F, egg galleries.

Pronotum 0.70 times as wide as long, widest on basal third; sides rather strongly arcuate on basal three-fourths, rather strongly constricted just behind broadly, shallowly emarginate anterior margin; surface smooth with rather fine, shallow, close punctures on median third, becoming more finely punctured laterally; an indistinct median line apparent. Vestiture very short, rather sparse, inconspicuous.

Elytra 1.5 times as long as wide, 2.2 times as long as pronotum; sides straight and subparallel on basal two-thirds, rather broadly rounded behind; basal margins arcuate, bearing a row of about nine moderately large, raised, overlapping crenulations with several smaller submarginal ones particularly on interstriae 2 and 3; striae weakly impressed, punctures rather small and shallow; interstriae about twice as wide as striae, armed by abundant, confused, small, transverse crenulations, each averaging about one-third width of an interstriae, never more than half as wide on posterior half of disc. Declivity moderately steep, convex with a feeble impression between striae 1 and 3; strial punctures reduced in size; interstrial punctures ranging from finely granulate to not at all granulate, abundant, confused (about three to four irregular ranks across width of an interstriae). Vestiture rather abundant, short, averaging about half as long as width of an interstriae, never as long as its entire width.

Female.-Similar to male except lateral elevations of frons less prominent and unarmed, with median groove consequently less conspicuous; arms of epistomal process less strongly elevated; pronotal constriction largely filled by a prominent transverse elevated callus both laterally and dorsally; punctures of pronotal disc very slightly larger and deeper; transverse crenulations of elytral disc very slightly larger; and declivital granules much finer, only a few punctures with a minute granule on upper margins.

Distribution.- British Columbia to Baja California, Chihuahua, and W Texas.

CANADA: British Columbia: Aspen Grove, Little Shuswap Lake, "Midday Ck." in Indian Meadow, Midday Valley, "Spious Ck.," Summerland, "Trepan Ck.," and "Trepanier Ck." USA: Arizona: Carr Canyon, Chiricahua Mts., Coconino N. F., Crow King, "Deadmans Flat" (Coconino Co.), Flagstaff, Ft. Apache, "Fort Valley," Grand Canyon N. P., Groom Ck. (Prescott N. F.),

Huachuca Mts., "Pleasant Valley," Prescott, San Francisco Mts., Santa Catalina Mts., Santa Rita Mts., Springerville, Walnut Canyon N. M., Williams, "Willow Rock," and Young. California: All counties. Colorado: Dolores, Ft. Garland, "Vallecito R. S." (La Plato Co.), Monte Vista, and Uncompahgre N. F. Idaho: Boise, Cedar Mt., Centerville, Coeur d'Alene, Garden Valley, Kooskia, Moscow, Pioneer, Placerville, Smith's Ferry, Stites, and Troy. Montana: Missoula. Nevada: Las Vegas. New Mexico: Capitan Mts., Cloudcroft, Datil, Gloriela Mesa, Mescalero, Mimbres, Ruidoso, Santa Fe, Santa Catalina Mits., Zuni Mits., and Jeremejo Park. Oregon: Ashland, Bend, Blue Mts., Bly, Burnt River, Chiloquin, Cold Springs, Colestin, Corvallis, "Dutch Ck.," Fremont N. F., Ft. Rock, Grants Pass, Jenny Ck., Joseph, Keno, Klamath Falls, Klamath Indian Res., Prineville, "Pringle Falls," Siskiyou Mts., Sisters, Sumpter. Wallowa Mts. Texas: Big Bend, Davis Mts. Utah: Daves Hollow (Dixie N. F.), Escalante, Panguitch, Pin Hollow (Fish Lake N.F.), Ashley N. F. Washington: Blue Mts., Buckeye, Chelan, Dayton, Kooskooskie, Northport, Pullman, Toppenish. MEXICO: Chihuahua: Tres Rios.

Hosts.- Pinus ponderosa, P. coulteri, and uncommon in other Pinus except during epidemics.

Biology.- This species probably has killed more merchantable timber in North America than any other organism in historic time. Miller and Keen (1960:1) estimate that approximately one billion board feet of standing timber have been destroyed annually in

Fig. 58. Dendroctonus brevicomis: Distribution map.

Pacific Coast states since studies commenced over half a century ago; this estimate may almost double if losses in British Columbia and the mountain states are included.

Overwintering parent adults and brood may become active at any period when subcortical temperatures become sufficiently high, probably somewhere in the vicinity of 45 to 50 F . The dates at which favorable conditions for flight occur in the spring vary considerably from year to year and from locality to locality depending on exposure, altitude, latitude, weather, and other ecological factors. In general the first of the overwintering adults and brood emerge to attack new trees about the first of May. Attacks from these beetles ordinarily continue until the latter part of June. A particularly early or late season, or a change in latitude north or south of the center of distribution may alter these dates by as much as a month. In the extreme southern limits of distribution it is possible that some flight activity may continue throughout the year. Because beetles do not emerge simultaneously, but do so slowly over a considerable period of time, and because of overlapping broods, some flight activity continues throughout the summer season; periods of greatest flight activity coincide with the emergence of each new brood. Flight activity is discontinued in October or November when daytime temperatures fall below 50 F .

Trees selected for attack usually are living, standing, and larger than 12 inches ( 30 cm ) DBH. Prostrate trees are seldom attacked. In the absence of competing species the attack normally is distributed from the ground level upward to areas as small as four to eight inches in diameter, where cork plates of the bark have formed. Younger bark of limbs or upper bole and of smaller trees where cork plates have not developed are rarely attacked. In the presence of competing species of Dendroctonus, particularly adjunctus Blandford, and to a lesser extent ponderosae Hopkins, the area of attack by brevicomis is forced upward from the ground level a variable distance depending on the comparative abundance of competing species.

The attack usually begins in the upper midbole area of the host tree then progresses upward and downward. The attack is slow
and continuous, without any sudden or concerted swarming of the beetles. Its duration is variable, evidently depending upon resistance of the host, or upon climatic or other ecological factors peculiar to the season or locality. It may be completed in as little as seven days, or it may continue over the greater part of a year. Characteristically the attack will be concentrated on one particular tree until it is overcome, even when the beetle population is high, before an attack is started on a second nearby tree. There is no attempt to occupy all available bark; the density of individual attacks may be as low as an average of about five per square foot of suitable bark on a susceptible tree, or higher than 20 per square foot on a vigorous or resistant tree. In general, single tree attacks suggest an endemic condition, while group attacks suggest an epidemic condition.

The winding egg galleries are constructed almost entirely in the inner bark or phloem tissues; they are in continual contact with and very lightly score or stain the woody or xylem tissues. Their total lateral displacement usually is equal to or greater than the total longitudinal displacement, although an occasional gallery may be decidedly longitudinal.

The diameter of an individual egg gallery is slightly greater than the width of a beetle; it averages approximately 35 cm in length, although exact measurements of fully formed galleries are virtually impossible to obtain because of the tendency for the winding galleries to branch, to anastomose, and to cross and recross one another. It is not uncommon for more than one pair of beetles to occupy one gallery, usually each pair being found in different branches that use the same entrance hole. Presumably this habit has suggested a tendency toward polygyny to some workers, particularly when the male was late in arriving or failed to arrive at all.

The initial attack is made by the female, usually in a crevice of the bark. About the time she reaches the phloem tissues where the pitch begins to flow she is joined by the male, who then assists her by pushing the excavated frass out of the entrance hole. Continuation of the parental or egg gallery is performed entirely by the female beetle. After several inches of gallery have been
cleared and the frass ejected from the entrance hole, the male then packs the frass in the lower regions of the gallery, thereby closing the entrance hole and tightly filling the gallery except for a few inches in the area where the beetles are working. It has been estimated (Miller and Keen 1960:16) that about two-thirds of an inch ( 2 cm ) of new gallery is formed each day. Mating occurs only after the female has been joined by the male, never on the surface of the tree before the attack begins. Although seldom seen, mating evidently occurs repeatedly, because it has been observed in various stages of gallery construction.

Ordinarily, but not always, the entrance tunnel is without a nuptial chamber or other means of turning around until the first ventilation tunnel or branch in the gallery is reached. Ventilation tunnels are placed at irregular intervals and are not always present. Their presence appears related to the stage of gallery construction, thickness of the bark, and activity of the beetles. Usually they are not constructed before the entrance hole is plugged by frass; they are less abundant or sometimes entirely absent in trees having comparatively thin bark; and they appear to be more numerous in galleries constructed by unusually active beetles. Seldom are they spaced at intervals of less than 5 cm .

Oviposition ordinarily begins about eight days after the attack and continues for approximately 10 to 49 days (Miller and Keen 1960:20), except when egg-laying is interrupted by winter, in which case it is greatly extended. Although estimates of the number of eggs produced by a female based on the average number of eggs per inch of gallery have suggested a figure much higher, the highest number actually reported is 41 (Miller and Keen 1960:19). Usually a majority of the eggs are deposited in the first third of the gallery, the number declining significantly in the final third.

Egg niches are symmetrical and ordinarily are constructed on the sides of the gallery, usually in contact with the cambium. They are broad and deep, the depth being equal to about one-fourth to one-third the diameter of the egg gallery. The deepest point is rounded, matching rather well the anterior profile of the parent beetle as seen from the
dorsal aspect. Unfilled egg niches often cannot be distinguished from the beginning of a new branch of the gallery. The number and spacing of niches depends on many factors, but usually the minimum distance between eggs on a particular side of a gallery is 1 cm . When considering both sides of the gallery and the alternating placement of eggs, this distance is reduced by half. Eggs are deposited individually in the niches; each niche is then filled by specially prepared frass packed to the original level or contour of the gallery.

Following the period of oviposition, the gallery may be continued in an irregular feeding tunnel of somewhat greater diameter than usual until death of the parent beetle; or the beetles may construct an exit tunnel, often independent of one another, by extending one of the ventilation tunnels and emerge to attack another host tree. It has been estimated that up to 50 percent of the parent beetles reemerge to produce a second brood, and a few of these reemerge to produce their third brood of the season (Miller and Keen 1960:18). Of those beetles that reemerge from the host, males predominate significantly.

The incubation period has not been determined precisely. Available figures suggest that 7 days are required for hatching under optimum conditions (Miller and Keen 1960:20), presumably with longer periods required when less favorable conditions exist. The newly hatched larvae mine the phloem next to the cambium for approximately 1 cm at right angles to the egg gallery. They then move into the inner bark and end their tunnels near the outer bark, where an area is cleared for pupation. Under optimum conditions larval development may be completed in as little as 30 to 35 days (Miller and Keen 1960:24); however, they do not develop at the same rate and some may require as much as 300 days to complete the larval stage of development. In the pupation cell the larva undergoes physiological changes to become a quiescent prepupa for about two to seven days before pupation occurs (Miller and Keen 1960:30); mature larvae may overwinter as prepupae, apparently never as pupae. Under normal conditions about 6 to 20 days are required to complete the pupal stage (Miller and Keen 1960:31); unfavorable conditions
may extend this period. A maturation period between attainment of the adult stage and emergence from the host varies from 7 to 14 days (Miller and Keen 1960:31), except in the spring months when it may be somewhat longer.

The number of generations each year is complicated by peculiarities of a particular season, by reemergence of parent adults to produce a second or a third brood, and by overlapping generations. In the northern parts of its range one complete and a partial second generation appears normal; in southern California and in Arizona three complete and perhaps a partial fourth generation might be expected.
Notes.- The above treatment was based on the holotypes of brevicomis and barberi, and on about 2500 other specimens. The Arizona, Utah, and Colorado specimens tend to be slightly larger and with slightly coarser elytral crenulations than those from the Pa cific Coast. However, series with equally
coarse elytral crenulations came from northern California.

## 2. Dendroctonus vitei Wood <br> Fig. 59

Dendroctonus ritci Wood, 1975(1974), Great Basin Nat. 34:289 (Holotype, male; Patžun, Guatemala; Wood Coll.)
Diagnosis.- This species is distinguished from mexicanus Hopkins by the larger size, by the darker color, by the sculpture of the pronotum and elytra, and by other characters indicated below.

Male.- Length $2.6-4.6 \mathrm{~mm}, 2.2$ times as long as wide; color almost black.

Frons similar to mexicanus except epistomal process wider ( 67 percent of epistomal width, 58 percent in mexicanus), its lateral arms much more strongly elevated; area from epistomal process to lateral summits on frons more strongly, more broadly impressed (often subconcave), more finely sculptured; largest

Fig. 59. Dendroctonus spp., distribution map; A, frontalis, open triangles; B, mexicanus, solid triangles; C, ritei, open circles.
tubercles at and near lateral summits less numerous, smaller than in mexicanus.

Pronotum similar to that of mexicanus except punctures averaging much smaller, closer, interspaces averaging less than half diameter of a puncture; interspaces over most of surface minutely granular, subshining, smooth shining areas usually restricted to less than one-fifth of total surface (in mexicamus interspaces average more than half diameter of a puncture, their surface smooth, brightly shining over almost entire surface, granulation rare and restricted; small tubercles sometimes occur in lateral areas). Vestiture more uniformly distributed, slightly coarser and longer than in mexicanus.

Elytra similar to mexicanus except discal striae less strongly impressed, punctures averaging smaller, obscurely impressed to obsolete in most specimens (larger and rather distinctly impressed in most mexicanus); interstrial crenulations narrower, lower, more numerous, rarely as much as one-third of crenulations at least half as wide as an interstriae, a few extend entire width of an interstriae). Declivity with striae feebly if at all impressed, punctures usually obsolete (striae and punctures rather strongly impressed in mexicanus); interstriae feebly if at all convex, crenulations less numerous and much smaller than in mexicanus. Vestiture slightly more abundant and coarser than in mexicanus, particularly at sides.

Female.- Similar to male except epistomal process narrower, not as high, frontal summits more poorly developed, usually not tuberculate; pronotal callus more poorly developed than in female mexicanus.

Distribution.- Guatemala.
GUatemala: Patzín, 19-1N-74, 12-111-74, 22-V-74, 9-X-74, 14-X-74, Pinus tenuifolia, "P. maximinoi," J. P. Vité, R. Lühl; Puente Tzantzir, Sololá, 2-II-72, P. montezumae, E. W. Clark.

Hosts.-Pinus pseudostrobus, $\quad P$. tenuifolia.

Biology.- This species occurs mostly at elevations above 2000 m . Its habits are very similar to mexicanus, but it apparently has a shorter life cycle. The pheromones are unique (Vité, Islas, Renwick, Hughes, Kleiforth 1974).

Notes.- The above treatment was based on the type series of 355 specimens.
3. Dendroctonus frontalis Zimmermann Figs. 59, 60, 61

Dendroctonus frontalis Zimmermann, 1868, Trans. American Ent. Soc. 2:149, 173 (Holotype, male; Carolina; Mus. Comp. Zool.)
Dendroctonus arizonicus Hopkins, 1909, U.S. Dept. Agric. Bur. Ent. Tech. Bull. 17(1):95 (Holotype, female: Williams, Arizona: U.S. Nat. Mus.. 74.46); Wood, 1974, Great Basin Nat. 34:188. Synonymy
Diagnosis.- This species is distinguished from the closely related brevicomis LeConte by the longer declivital pubescence, by the more strongly impressed declivital striae, by the more sparsely but more coarsely granulate punctures of the declivital interstriae, by the smaller average size, and, in part, by the distribution.

Male.- Length 2.0-3.2 mm (average about 2.8 mm ), 2.3 times as long as wide; mature color light brown to dark brown.

Frons convex, with a pair of lateral elevations on median half just below upper level of eyes separated by a deep median groove, summits of elevations armed at their dorsomedian margins by one or two prominent, somewhat dorsomedially oriented granules; epistomal margin elevated, its surface smooth and shining; epistomal process slightly wider than half ( 0.58 times) distance between eyes, its arms oblique (about 40 degrees from horizontal) and elevated, horizontal portion about half its total width, transversely concave, ending just above epistomal margin and bearing under its distal margin a dense brush of conspicuous yellowish setae; surface gran-ulate-punctate above eyes, coarsely, rather deeply punctured and subgranulate below. Vestiture, in addition to epistomal brush, rather long, sparse.

Pronotum 0.73 times as long as wide, widest on basal third; sides rather weakly arcuate on basal three-fourths, rather feebly constricted just behind broadly, shallowly emarginate anterior margin; surface smooth with rather coarse, moderately deep, close punctures; punctures somewhat shallower and less abundant laterally but not reduced in size; a raised median line not apparent. Vestiture rather long, fine, sparse.

Elytra 1.6 times as long as wide, 2.2 times as long as pronotum; sides straight and subparallel on basal two-thirds, rather broadly rounded behind; basal margins arcuate and bearing a row of about nine moderately
large, raised, overlapping crenulations, with several smaller submarginal ones particularly on interstriae 2 and 3; striae rather strongly impressed, punctures rather small, moderately deep; interstriae moderately convex, about one and one-half times as wide as striae and armed by a single very irregular row of rather coarse transverse crenulations, each
averaging well over half width of an interstriae. Declivity moderately steep, convex; striae rather strongly impressed, punctures only slightly smaller than on disc; interstriae convex, virtually all punctures rather coarsely, transversely tuberculate, arranged in an irregular single or partly double rank (never more than two ranks across an

Fig. 60A. Dendroctonus frontalis: A, female head; B, male head; C, male head and pronotum (left); D, female head and pronotum (right); E, elytral declivity; F, male seminal rod; G, galleries.
interstriae). Vestiture rather abindant, rather long, length of most hairs equal to width of an interstriae, a few twice as long.

Female.- Similar to male except lateral elevations of frons less prominent and unarmed, with median groove consequently less conspicuous; arms of epistomal process flat; pronotal constrictions largely filled by a prominent transverse elevated callus both laterally and dorsally; punctures of pronotal dise very slightly larger and deeper; transverse crenulations of elytral disc very slightly larger; and declivital granules somewhat finer, a few punctures along edges of interstriae often without granules.

Distribution.- Oklahoma and Pennsylvania to E Arizona, Florida, and Honduras.

USA: Alabama: Calhoun, Montgomery. Arizona: Copper Basin Road near Prescott, Flagstaff, Santa Catalina Mts., Santa Rita Mts., Walker, Williams. Arkansas: Hampton. District of Columbia: Washington. Florida: Haw Ck., Taylor Ck. Georgia: Clyo, Demorest. Thomasville. Louisiana: Singer. Wilson. Maryland: Cumberland. North Carolina: Asheville, Biltmore, Black Mts., Boardman, Fletcher, "Mt. Graybeard," Pisgah Ridge, Tryon. Oklahoma: "Western Indian Terr." Pennsylvania: Mt. Alto. South Carolina: "Ben Quan," Clemson. Georgetown, Pregnall. Tennessee: Ducktown. Texas: Beaumont, Call, Dewevville. Kirbyville. Virginia: Arlington, Auburn, Chase City, Cob Island, Glen Allen, Green Bay, King and Queen Co., Port Republic, Virginia Beach. West Virginia: Greenbrier, Hampshire, Hardy, Kanawha, Monongalia, Pendleton, Pocahontas, Raleigh. Randolph. Tucker, Wood cos. HONDURAS: Yuscaran.

Hosts.- Pinus echinata, P. engelmannii, $P$. glabra, P. oocarpa, P. palustris, P. ponderosa, P. rigida, $P$. strobus, $P$. taeda, and $P$. virginiana. Contrary to the statement of Thatcher et al. (1980), five series from P. ponderosa
were examined from northern Arizona where $P$. engelmannii does not occur.

Biology.- The winter is passed in all stages, including eggs, with larvae predominating. As with brevicomis, activity might resume whenever subcortical temperatures become favorable during or following the winter months. There are three generations each year in the north (Thatcher et al. 1980), but, because all stages overwinter and emerge from the host as they mature, there is an extreme overlapping of generations, resulting in an almost continuous period of flight from April, when the first flights of overwintering adults begin, until December, when activity ceases in the northern parts of the range. In Honduras it is expected that flight activity is continuous throughout the year without interruption. In any particular locality, however, there are periods of greatest flight activity that tend to coincide with the emergence of each new brood. According to Hopkins (1909b:62), a peculiarity of this species is its tendency to migrate considerable distances from the brood tree to begin a new attack; subsequent workers (Dixon and Osgood 1961:6) also indicated that trees selected for attack may be either nearby or considerable distances from the point of emergence, but they tend to be scattered, not clustered.

Trees selected for attack ordinarily are living, standing, and larger than about six inches DBH. The attack usually is concentrated on the upper half of the bole but may reach the

Fig. 60B. Dendroctonus sp., posterior half of left side of pronotum: 1, frontalis; 2, citei. (Both photographed at 200 X .)
ground level. The attack is slow and continuous, its durations depending on numerous factors such as the size and resistance of the host, the population density of beetles in the area, and the climatic and other ecological factors peculiar to the area. The duration and general pattern of attack on a host tree evidently are similar to those of brevicomis.

The egg galleries are almost entirely in the phloem tissues, not engraving, but staining the xylem slightly. They are winding, elongate galleries, often branching, anastomosing, or crossing one another. The complicated interwoven series resembles rather closely that of brevicomis, except that there is a greater tendency for the galleries to be longitudinal; that is, for the total longitudinal displacement to exceed the total lateral displacement. The diameter of each egg gallery is slightly greater than the width of a parent beetle; in length they average approximately 30 cm , although the winding, complex character of the galleries makes accurate measurement virtually impossible.

As with other species of the genus, the initial attack is made by the female, usually in a crevice in the bark. The male joins the female about the time the pitch begins to flow; he then pushes the frass from the entrance hole while the female extends the gallery. After the gallery has been extended several centimeters he packs the lower areas with frass, thereby blocking the entrance hole, leaving only the area where the beetles are working free for their activities. The gallery may or may not have a nuptial chamber; ventilation tunnels may be spaced irregularly as in brevicomis. Extension of the egg gallery may occur at the rate of about 2.5 cm per day. (Dixon and Osgood 1961:6).

The small amount of published data pertaining to the period of oviposition, egg production by individual females, and details of gallery formation are not sufficient for conclusive statements concerning them; however, it does permit the following comments.

Drawings, photographs (Hopkins 1909b:58-68, Fronk 1947:9; Dixon and Osgood 1961:7; etc.), and limited personal observations of egg galleries indicate that egg niches are placed alternately along the sides of the gallery in contact with the cambium. They are symmetrical and about one-third as
deep as the width of the gallery and slightly wider than deep. The spacing of niches appears variable, but evidently they may be as close as 6 mm , with an average of 17 mm between niches on one side (accurate measurements should provide figures much lower than these). Eggs are deposited individually and each is packed in its niche with specially prepared frass to the original contour of the gallery.

Fronk (1947:10) found that under optimum conditions the eggs hatch in 3 to 9 days, with an average of 5.5 days; unfavorable conditions such as occur during the winter evidently may lengthen the incubation period to several months. Each newly hatched larva mines the phloem in contact with the cambium, approximately perpendicular to the egg gallery. This mine of the first instar larva is of uniformly thin diameter for about 1 cm , or several times this length in an unfavorable environment (Hopkins 1909:61); it then widens abruptly into a short, irregularly oval

Fig. 61. Dendroctonus frontalis: A, egg; B, larva; C, pupa; D, adult. (After Bennett and Ciesla 1971:5.)
area, where the remaining larval instars are passed (Fronk 1947:8). This enlarged area may be in contact with the cambium and visible on peeled bark, or in thick bark it may be entirely in the inner bark, as in brevicomis. Toward the end of the fourth instar the larva bores into the outer bark, where it clears a pupal chamber and enters the quiescent prepupal stage. The larval period under optimum conditions varies from 25 to 38 days and the pupal period about 8 to 11 days (Fronk 1947:6); either or both stages might be lengthened several months by unfavorable conditions. In Virginia the life cycle was completed under near optimum conditions in from 40 to 54 days (Fronk 1947:7).

The number of generations completed in one year varies from 3 to 5 in the eastern United States; in Honduras the number may be greater.

Notes.- Recent studies of pheromone attraction in Mexico and Honduras by J. P. Vité indicate that frontalis occurs in Honduras at elevations below 1000 m . It is replaced by a sibling species, mexicanus, at higher elevations. Due to the recent discovery of this differential pheromone attraction, the only other biological character noted in the Honduras frontalis population is that the life cycle is completed in about 60 days; the life cycle is significantly longer in mexicanus. The two populations often can be distinguished anatomically only when long series are studied.

The holotype of frontalis and about 700 other specimens were examined. Based on anatomical characters mentioned in the above key, I grouped material from Arizona, New Mexico, the southeastern United States, and part of that from Honduras under frontalis. Reliable observers also reported this species from elevations less than 700 m in eastern Mexico, but I have not seen specimens that document the reports. Specimens taken above 700 m elevation from Mexico to Honduras are of mexicanus (Wood 1975:288). Because the Arizona specimens are distinguished from mexicanus with extreme difficulty, it is possible that some gene flow between these forms occurs in northern or eastern Mexico; however, in Honduras both forms may breed in the same trees in the area of altitudinal overlap, with the mexicanus
population having a distinctly longer life cycle. In Honduras they behave as distinct species. A third species in this complex, vitei Wood, from Guatemala, is distinguishable by several characters.

## 4. Dendroctonus mexicanus Hopkins Fig. 59

Dendroctonus mexicanus Hopkins, 1905, preprint of Proc. Ent. Soc. Washington 7:80 (Lectotype, female: Sacramento, Amecameca, Mexico, Mexico; U.S. Nat. Mus., 7518, present designation)

Diagnosis.- This species is distinguished, with difficulty, from frontalis Zimmermann by the larger than average size, by the darker mature color, by the concave area on the female frons above the epistomal process, by the smaller or obsolete strial punctures that usually have fine crenulations between them, and by the longer life cycle.

Male.- Length 2.3-3.7 mm (average about 3.2 mm ); 2.3 times as long as wide; color medium brown to black.

Essentially identical to frontalis except as noted in diagnosis and key.

Distribution.- Chihuahua to Honduras.
MEXICO: Chiapas: Huixtla. Chihuahua: Tres Ríos. Distrito Federal: Mexico, Tacubaya. Hidalgo: Jacala. Mexico: Amecameca, Chapingo, San Rafael, Texcoco, Tlalmanalco. Michoacán: "Michoacán." Morelos: Cuernavaca, Tlavacapan. Puebla: Texmelucán. Tlaxcala: Tlaxcala. Zacatecas: Laguan Balderama. GUATEMALA: Godenez, Santa Cruz del Quiché. HONDURAS: Yuscarán.

Hosts.- Pinus ayacahuite, P. lawsoni, P. leiophylla, P. montezumae, P. oocarpa, $P$. ponderosa, P. pseudotrobus, P. rudis, $P$. teocote.

Biology.- Evidently as in frontalis except the life cycle is longer than 90 days. The altitudinal distribution evidently is above 700 m ; in frontalis it is mostly below 700 m , but both species have been taken from the same tree in Honduras. Trees selected for attack usually are clustered; in frontalis they tend to be scattered.

Notes.- The above treatment was based on the lectotype of mexicanus, and on about 600 other specimens. This species was regarded (Wood 1963) as a synonym of frontalis because of the extreme variability of series from Honduras. When Vité (pers. comm.) was unable to attract all segments of the population in Honduras and none of it in

Mexico with frontalis pheromones, the species was reexamined. Differences in life cycle, attack pattern, and morphology then became apparent. The two species are extremely difficult to distinguish using anatomical characters unless series are examined.

See the above notes under frontalis for additional information on this species.

## 5. Dendroctonus approximatus Dietz <br> Figs. 62, 63

Dendroctonus approximatus Dietz, 1890. Trans. American Ent. Soc. 17:28 (Lectotype, female; Colorado; Philadelphia Acad. Sci., designated by Hopkins, 1909, U.S. Dept. Agric. Bur. Ent. Tech. Bull. 17(1):102)
Dendroctonus parallelocollis: Of all authors except Chapuis; Wood, 1969, Great Basin Nat. 29:121 (Erroneous identification corrected)

Fig. 62. Dendroctonus approximatus: A, female head: B, male head; C, female head and pronotum; D, male head and pronotum; E, male seminal rod: F, galleries.

Diagnosis.- This species is distinguished from frontalis Zimmermann and mexicanus Hopkins by the larger size, by the more nearly flattened declivital interstriae with 2 weakly impressed, by the uniseriate, rounded granules on declivital interstriae 2 , and by the larger, more closely set crenulations of the elytral disc. From adjunctus Blandford it is also distinguished by the more strongly impressed declivital striae, by the interstrial granules being uniseriate only on declivital interstriae 2 (rarely also on 1) and much more closely spaced, by the much larger, more numerous crenulations of the elytral disc, and by the more prominent transverse pronotal callus of the female and the large, almost hornlike, frontal tubercles of the male.

Male.- Length 4.5-7.0 mm (average about 5.5 mm ), 2.3 times as long as wide; mature color very dark brown to black.

Frons convex, with a pair of lateral elevations on median half just below upper level of eyes separated by a deep median groove, summits of elevations armed at their dorsomedian margins by one or two prominent, somewhat dorsomedially oriented tubercles; epistomal margin elevated, its surface smooth and shining; epistomal process slightly wider than half ( 0.57 times) distance between eyes, its arms oblique (about 40 degrees from horizontal) and elevated, horizontal portion about half its total width, transversely concave, ending just above epistomal margin and bearing under its distal margin a dense brush of conspicuous yellowish setae; surface punc-tate-rugulose above eyes, coarsely, rather deeply punctured and subgranulate below. Vestiture, in addition to epistomal brush, rather long, sparse.

Pronotum 0.80 times as long as wide, widest at base; sides feebly arcuate and converging very slightly to almost imperceptible anterior constriction just behind broadly, very shallowly emarginate anterior margin; surface smooth and shining, punctures rather small, moderately deep, close (size, depth, and arrangement variable in a series); a raised median line feebly indicated anteriorly. Vestiture sparse, inconspicuous; moderately long at sides.

Elytra 1.3 times as long as wide, 2.2 times as long as pronotum; sides straight and subparallel on basal two-thirds, rather broadly
rounded behind; basal margins arcuate and bearing a row of about nine moderately large, raised, overlapping crenulations, with several smaller submarginal ones particularly on interstriae 2 and 3; striae weakly impressed, punctures usually rather small and shallow with anterior margins raised, subcrenulate; interstriae about twice as wide as striae and armed by abundant, confused, transverse crenulations, each averaging at least half width of an interstriae, some as wide as an entire interstriae on posterior half of disc. Declivity moderately steep, convex, with interstriae 2 weakly impressed; striae narrowly, moderately impressed, punctures smaller than on dise, distinctly impressed, l and 2 almost straight, 3 curving away from suture on upper half, toward suture on lower half: interstriae scarcely if at all convex, about equal in width (except for expanded portion of 3 ), each bearing a series of moderately large rounded granules, those on 1 and 3 usually confused, uniseriate on 2 , usually with a few to many fine punctures in addition to granules; granules on interstriae 2 separated from one another by an average distance equal to one-half width of an interstriae. Vestiture not abundant, longer on sides and declivity, longest setae about one and one-half times as long as width of an interstriae.

Fig. 63. Dendroctonus approximatus, distribution map.

Female.- Similar to male except lateral elevations of frons less prominent and unarmed, with median groove consequently less conspicuous; arms of epistomal process less strongly elevated; pronotal constriction largely filled by a prominent, transvere, elevated callus both laterally and dorsally; punctures of pronotal disc very slightly larger and deeper; transverse crenulations of elytral disc and declivital granules somewhat larger.

Distribution.- Central Utah and Colorado to Honduras.
USA: Arizona: Black Mesa F. R., Chiricahua Mts.. Flagstaff, Fort Apache, Graham Mts., Grand Canyon N. P., Kaibal) N. F., Paradise. Pine, Portal, Prescott, Rincon Mts., Santa Catalina Mts., Santa Rita Mts., Show Low, Tucson, Williams. Colorado: Brookvale, Glen Haven, Las Animas, La Veta, Monte Vista, Palmer Lake. New Mexico: Capitan Mts., Carson N. F., Cloudcroft, Lincoln N. F., Santa Fe, Sierra Blanca. Utah: Bryce Canyon N. P., Dixie N. F., Escalante, Kamas, Long Hollow, Panguitch, Panguitch Lake, Pin Hollow in Fishlake N. F. MEXICO: Chihuahua: Chuichupa, Tres Ríos. Durango: El Salto, Sierra Durango. Distrito Federal: Mexico. Mexico: Ixtaccihuatl. Michoacán: Jacona. Morelos: Jonacatepec. Oaxaca: Oaxaca. Puebla: Texmelucán. Tlaxacala: Tlaxacala. Veracruz: Jalapa, Veracruz. cuAtEMALA: Quezaltenango, Santa Cruz del Quiché, Tecpán. HONDURAS: San Pedro Sula.

Hosts.- Pinus ayacahuite, P. chihuahuana, P. engelmannii, P. hartwegii, P. leiophylla, P. montezumae, P. ponderosa, $P$. teocote.

Brology.- This is not an aggressive species; consequently, damage caused by it is comparatively minor. It is a secondary enemy of pine, entering the host only after the tree has been overcome by the more aggressive species of Dendroctonus or of Ips.

Adults and larvae in all stages of development overwinter in their galleries at the base of the host tree, or, in the case of felled trees, on the lower side of the trunk next to the ground. They become active somewhat later than other species and usually extend their old galleries for a period, with the adults resuming egg-laying activities, before emerging from the host. In the northern parts of the range the flight period begins early in June and continues until October, with the principal period of activity occurring in June and early July. In southern Mexico and Guatemala activity probably continues throughout the year without seasonal interruptions. Emergence from the host occurs
gradually over a long period of time; consequently, large numbers of beetles are not in flight at the same time, making a concerted attack on one tree by this species exceedingly difficult.

The trees selected for attack are those previously selected by and largely overcome by other species, or those felled more than six weeks prior to the attack. This species usually occupies the basal portion of the bole from the ground level up to a height of six or eight feet. In the northern parts of its range, where it competes with adjunctus for space in the basal parts of the host, its galleries seldom extend more than two or three feet above the level of the ground. It also breeds in felled trees (Blackman I931:30), usually only on the lower side, particularly in those areas in contact with the ground. The smallest trees observed in which this species was breeding were 12 inches DBH, although this probably does not represent the minimum size acceptable to this species.

Ordinarily the attack is directed at the butt of the tree in areas of bark not occupied one to three weeks previously by other species. In an injured tree the attack may extend over a rather long period of time as successive generations slowly girdle it.

Basically the galleries are longitudinal and winding; they are coarser than those of associated species, particularly adjunctus, and present a strikingly different overall pattern. Branch galleries, many of which cross or join other galleries, are numerous, causing the entire network of galleries to form an apparently aimless crisscross pattern. As with other species, the galleries are almost entirely in the inner bark, very faintly grooving or at least staining the cambium.

The egg galleries are rather coarse, averaging about 5 mm in diameter. Gallery systems may be extensive, but because of their branching and anastomosing character it is virtually impossible to measure the work of individual beetles.

The initial attack is made by the female, and soon after she reaches the phloem tissues she is joined by the male. He then expels excess frass from the entrance hole or later packs the lower or more remote areas of the gallery with excess frass to keep clear the area where the female is working. Egg niches
are very different from other species; they are not in contact with the cambium, but are located alternately on the sides of the wall farthest from the cambium. The niches are cup-shaped, larger than usual, and extend into the nonliving portion of the bark. Each niche may contain one to four eggs (Blackman 1931:30); no more than one egg per niche was found during my study. The larval mines are entirely in the bark, mostly in the outer bark, and do not contact the cambium at any time. Their length is variable and not easily measured, but evidently they are rather short. Pupal chambers are almost always in the outer bark.

Oviposition apparently begins about a week before the attack and probably continues over a substantially longer period than is the case with related species. The position of the egg niches and the possible deposition of several eggs in each makes it difficult to count with any degree of accuracy the number of eggs produced by any one female, because many of the eggs are destroyed by the observer's attempt to locate the niches. From the number of niches found, however, it is estimated that the number is not large, probably seldom exceeding 40 eggs per female. As with other species, a majority of the eggs apparently were deposited in the first third of the egg gallery. The exact spacing of egg niches, and the periods of incubation and larval and pupal development were not determined.
In the northern parts of its range one generation per year appears to be normal.

Notes.- The above treatment was based on the lectotype and on about 550 other specimens. Due to misidentification of the type of parallelocollis by other authorities and to my inability to locate it for my revision of the genus, most of the literature treating this species prior to 1969 was published under the name parallelocollis.

## 6. Dendroctonus adjunctus Blandford Figs. 64, 65

Dendroctonus adjunctus Blandford, 1897. Biol. Centr. Amer., Coleopt. 4(6):147 (Lectotype, male; Totonicipan, Guatemala; British Mus. Nat. Hist., present designation)
Dendroctonus concexifrons Hopkins. 1909, U.S. Dept. agric. Bur. Ent. Tech. Bull. 17(1):87 (Holotype, female; Williams, Arizona; U.S. Nat. Mus., 7445); Wood, 1963, Great Basin Nat. 23:52. Synonymy

Diagnosis.- This species occupies a position between the two major groups within the genus, more or less compromising the characters of approximatus Dietz and ponderosae Hopkins. It is distinguished from approximatus by the more slender body form, by the more widely spaced, uniseriate granules on declivital interstriae $1-3$, by the more finely sculptured elytral disc, and by the absence of frontal tubercles in the male and the more poorly developed transverse pronotal callus in the female. In many respects it is similar to ponderosae but may be distinguished by the more slender form, by the smooth, shining, declivital interstriae, by the stronger median frontal groove, and, in the female, by the transverse pronotal callus.

Male.- Length $3.0-5.5 \mathrm{~mm}$ (average about 4.8 mm ), 2.4 times as long as wide; mature body color rather dark brown.

Frons convex, with a pair of unarmed lateral elevations on median half just below upper level of eyes separated by a rather inconspicuous median groove; epistomal margin elevated, its surface smooth and shining; epistomal process half ( 0.50 times) as wide as distance between eyes, its arms oblique (about 40 degrees from horizontal) and elevated, horizontal portion about half its total width, transversely concave, ending just above epistomal margin and bearing under its distal margin a dense brush of conspicuous yellowish setae; surface punctate-rugulose above eyes, more deeply punctured and subgranulate below. Vestiture, except epistomal brush, sparse, inconspicuous, rather long.

Pronotum 0.74 times as long as wide. widest on basal third; sides rather strongly arcuate on basal three-fourths, rather strongly constricted behind broadly, shallowly emarginate anterior margin; surface smooth with rather fine, shallow, close punctures on median third, becoming more finely punctured laterally; an indistinct median line apparent. Vestiture rather sparse, long, becoming coarse laterally.

Elytra 1.7 times as long as wide, 2.4 times as long as pronotum; sides straight and subparallel on basal two-thirds, rather narrowly rounded behind; basal margins arcuate and bearing a row of about nine moderately large, raised, overlapping crenulations, with

Fig. 64. Dendroctonus adjunctus: A, male head; B, female head; C, male seminal rod; D, galleries.
several smaller submarginal onces particularly on interstriae 2 and 3 ; striae weakly impressed, punctures rather small, shallow; interstriae about twice as wide as striae and armed by rather abundant confused, transverse crenulations, each averaging about onehalf width of an interstriae, a few almost as wide as interstriae on posterior half of disc. Declivity moderately steep, convex, with interstriae 2 weakly impressed; striae weakly impressed, punctures greatly reduced, 1 straight, 2 curving slightly toward suture on lower third, 3 diverging from suture on upperhalf, curving toward suture on lower third; interstriae 1 slightly raised, 2 impressed and flat, 3 feebly convex, each bearing a uniseriate row of sparse, rounded, or pointed granules and in addition several confused, minute punctures; granules on 2 separated from one another by an average distance equal to width of an interstriae. Vestiture rather sparse, longer on sides and declivity, longest setae about one and one-half or two times as long as width on an interstriae.

Female.- Similar to male except lateral elevations and median frontal groove poorly developed; arms of epistomal process less strongly elevated; pronotal constriction with a feebly developed transverse elevated callus: punctures of pronotal dise very slightly larger and deeper; and transverse crenulations of elytral dise and granules of declivity very slightly larger.

Distribution.-S Utah and Colorado to Guatemala.

USA: Arizona: Flagstaff, Fort Apache, Graham Mts., Grand Canyon N. P., Jacobs Lake, Kaibab N. F., Paradise, Rustler Park, Santa Catalina Mts., Show Low, Williams. Colorado: Durango, Ft. Garland, Las Animas Co., La Veta, Monte Vista, Rye, San Isabel N. F., "Vallecito R. S." New Mexico: Capitan, Carson N. F., Cloudcroft, Ft. Wingate, "Hermit Peak," Las Vegas, Lincoln N. F., Sierra Blanca, Vermejo. Utah: Escalante, Long Hollow in Dixie N. F., Manti-La Sal N. F., Panguitch Lake, Sanford Canyon. MEXICO: Mexico: Nevada de Toluca, Penuela la Gavia. GUATEMALA: Cerro Quemado, Chuchumatanes, Guatemala, La Esperanza, Las Trojadas, Montaña de las Nubes, Poptum, Quetzaltenango. Sierra María Tecum, Tecpan, Totonicapan.

Hosts.- Pinus ayacahuite, P. hartwegii, P. leiophylla, P. montezumae, P. ponderosa, P. pseudostrobus, P. tenuifolia.

Biology.- This species generally works in concert with other species of Dendroctonus to overcome a tree. Its galleries resemble, superficially at least, those of other species and,
consequently, the resulting misidentifications have attributed much of the damage actually done by this species to others having more formidable reputations as tree killers. In the absence of an epidemic of other species it appears much more aggressive than the available literature would indicate, frequently initiating the primary attack on a tree.

Although any stage of development may be represented, the winter usually is passed as half-grown larvae or else as adults starting a new attack in the fall but without commencing oviposition. Larval development is resumed and egg deposition is started or resumed as soon as spring temperatures become sufficiently high. The brood, both young adults and larvae, completes it development and begins to emerge to seek new hosts in May or early June, usually several weeks after the emergence of brevicomis and possibly of ponderosae. Its habits of commencing attacks in the fall and the late emergence in the spring are important factors in the apparent lack of aggressiveness of this species, because the timing of its flight activity coincides with the period when other species have overcome host trees but have not yet occupied the lower portions of the bole. (This could indicate a lack of seasonal synchrony in the life cycle that does not occur every year.)

Fig. 65. Dendroctonus adjunctus, distribution map.

Although some flight activity occurs throughout the summer months, two periods of increased activity occur. The first is in May and early June; the second and greatest occurs between the later part of August and the middle of October. The attack on a particular tree is spread over a considerable period of time and usually involves a relatively small population of this species.

Trees selected for attack are weakened standing trees larger than about 10 inches DBH. Galleries have been observed in stumps, but not in prostrate trees or logs. In the absence of competing species the area of attack may extend from ground level to a height of about 3 or 5 m ( 10 or 12 ft ). When competing species, particularly ponderosae, are present in large numbers this species may be restricted to less than the lower three feet of the bole.

The attack appears to begin in the upper parts of the area occupied by this species; that is, the bole about 1 to $4 \mathrm{~m}(4$ to 12 ft$)$ above the ground level, with successively newer attacks occurring below this area until the level of the ground is reached. The attack may be completed in a few days when populations are high, or it may extend over the greater part of a year, particularly when the first attacks are made in the fall.

Egg galleries are sinuous and almost always extend upward from the entrance hole. As with other species of this genus they are almost entirely in the phloem, very lightly scoring or at least staining the wood. The total longitudinal displacement of an egg gallery usually is about three to four times as great as the total lateral displacement. Ordinarily the gallery extends horizontally either right or left from the entrance hole about $4-7 \mathrm{~cm}$ then curves upward; about two to four broad sinuous curves are included in its vertical ascent. From the principal longitudinal axis of the gallery the first of these curves diverges about 4 to 6 cm from this axis. Of 36 egg galleries studied in the Panguitch, Utah, area during the last week of June 1960, the average gallery length was 31 cm and the maximum was 89 cm ; the average width was about 4 mm . Although it appeared that an effort was made by the beetles to avoid doing so, galleries did cross or anatomose occasionally. Approximately one
gallery in 25 descended vertically, evidently to avoid crowding or crossing neighboring galleries; more rarely one was primarily transverse. Branching or side galleries extending from the main egg tunnel were uncommon. When such branches did occur they usually did not exceed 3 cm in length and did not contain egg niches.

The initial attack is made by the female. As with other species this usually occurs in a crevice of the bark, ordinarily she is joined by the male about the time the entrance tunnel reaches the cambium, then the male ejects frass from the entrance hole while the female extends the gallery. When sufficient working space is available, he then packs the lower portions of the gallery with the excess frass.

Ventilation tunnels occur at irregular intervals; the minimum observed distance between two of them was 1.7 cm ; in trees having relatively thin bark they may be entirely absent. The average distance between ventilation tunnels in the 36 galleries measured for this study was 5.2 cm . The first most commonly is placed within 1 cm either above or below the first egg niche; the average distance from the entrance hole to the first egg niche was 3.5 cm .

Egg niches are arranged alternately in the phloem on the sides of the gallery in contact with the cambium. Each is symmetrical, slightly deeper than wide, and, compared to the foregoing species, is rather small. Each niche is very slightly larger than the egg it contains. The number and spacing of egg niches is variable; the minimum observed distance between two niches located on the same side of a gallery was 1.5 mm ; the average distance was about 3.5 mm . The average number of egg niches in the 36 galleries mentioned above was 44.1; the maximum was 119. About one-tenth of the niches were located exactly opposite one another on the different sides of the gallery; this was a notable departure from the consistently alternate placement of niches in the preceding species, where such an occurrence was exceedingly uncommon. Eggs are deposited individually in the niches; each niche is then filled by specially prepared frass to the original level of the gallery wall.

The period of incubation has not been determined precisely, but evidently it requires about a week under optimum conditions. The newly hatched larvae construct narrow tunnels in the cambium region perpendicular to the egg gallery. The larval mine extends about 1 to 4 cm along a straight to winding route, without increasing in diameter. It then expands abruptly into an oval to irregular feeding chamber approximately $0.5-1.0 \mathrm{~cm}$ wide and about 1 or 2 cm long. The entire larval mine usually is in contact with the cambium and is visible on the inner surface of peeled bark. Some of the larvae pupate in this chamber; most of them, however, mine into the outer bark for pupation.
The number of generations may vary from one complete and'a partial second generation per year to one generation in two full years (Hopkins 1909b:55). Although not reported, it appears possible that two generations might be completed in favorable years and localities in the southern parts of its range (Becker 1954).

Notes.- The above treatment was based on the syntypes of adjunctus, the holotypes of convexifrons, and on about 700 other specimens. The male syntype labeled "Type" is here designated on the lectotype of adjunctus Blandford, as indicated above.

## 7. Dendroctonus ponderosae Hopkins

Figs. 66, 67, 68, 69

Dendroctonus pondcrosue Hopkins, 1902, U.S. Dept. Agric. Div. Ent. Bull. 32:10 (Lectotype, female; Spearfish, South Dakota; U.S. Nat. Mus., 7448, present designation)
Dendroctonus monticolae Hopkins, 1905, U.S. Dept. Agric. Bur. Ent. Bull. 56:11 (Lectotype, female; Kootenai, Idaho; U.S. Nat. Mus., 7447, present designation); Wood, 1963, Great Basin Nat. 23:58. Synonymy
Diagnosis.- This species is distinguished with difficulty from jeffreyi Hopkins by the larger, closer deeper pronotal punctures and, in the area of sympatry, by the smaller average size. It is remotely allied to adjunctus Blandford but lacks the median frontal groove and the female pronotal callus, and the elytral declivity is minutely granular and dull.

Male.- Length $3.5-6.8 \mathrm{~mm}$ (average about 5.5 mm ; size varies geographically as
well as within local population), 2.2 times as long as wide; mature body color black.

Fronx convex from eye to eye, from vertex to epistoma, median line narrowly impressed above upper level of eyes, rather broadly protuberant over an indefinite median area below upper level of eyes, often with remnants of a narrowly impressed median line; epistomal margin elevated, its surface smooth and shining; epistomal process half as wide ( 0.50 times) as distance between eyes, its arms oblique (about 30 degrees from horizontal) and elevated along their median halves, horizontal portion about half its total width, transversely concave, overlapping and ending just above epistomal margin and bearing under its distal margin a dense brush of conspicuous yellowish setae; surface punctaterugulose above eyes, coarsely, rather deeply punctured and subgranulate below. Vestiture in addition to epistomal brush, rather long, sparse, inconspicuous.

Pronotum 0.75 times as long as wide, widest at base; sides feebly arcuate, almost straight on basal two-thirds, converging

Fig. 66. Dendroctonus ponderosae: A, eggs; B, larva; C, pupa; D, adult. (After Evenden, Bedard, and Struble 1943:6.)
slightly toward well-developed constriction just behind broadly, shallowly emarginate anterior margin; surface smooth, shining, with very close, rather small, moderately deep punctures (variable), becoming granulose laterally; a median line feebly indicated, more prominent anteriorly. Vestiture scanty, usually evident only at sides.

Elytra 1.5 times as long as wide, 2.1 times as long as pronotum; sides straight and subparallel on basal two-thirds, rather broadly rounded behind; basal margins arcuate and bearing a row of about nine moderately large, raised, overlapping crenulations, with several small submarginal ones particularly on interstriae 2 and 3 ; striae weakly impressed, punctures rather small, rather deep; interstriae about twice as wide as striae and armed by rather coarse, confused, transverse crenulations, each averaging about half width of an interstriae. Declivity rather steep, convex, with interstriae 2 rather strongly impressed; striae rather narrowly impressed, punctures smaller than on disc; striae 1 slightly, 2 rather strongly, 3 very strongly curved toward suture; interstriae usually at least slightly convex, minutely rugulose, dull, punctures fine, confused, distinct to obscure or subgranulate; each interstriae with a sparse, more or less definite median row of rather large granules. Vestiture scanty, longer and more conspicuous on declivity, longest setae slightly longer than a distance equal to width of an interstriae.

Female.- Very similar to male, but evidently epistomal process less well developed, and elytral crenulations and declivital granules a little larger.

Distribution.-S British Columbia and E South Dakota to Baja California and New Mexico.

Hosts.- Pinus albicaulis, P. balfouriana, P. contorta, P. coulteri, P. edulis, P. flexilis, P. jeffreyi (rare), P. lambertiana, P. monophylla, P. monticola, P. murrayana, P. ponderosa, P. strobiformis. During an epidemic it was recorded from Picea engelmannii.

Biology.- This has been referred to (Craighead et al. 1931:1009) as the most destructive species of Dendroctonus. Estimates of losses in our timber resources due to this insect are scattered, conflicting, and confused by the fact that this species has been known concurrently by two separate scientific names. Considering all factors, the average annual loss attributed to it since 1895 possibly may approach 1.5 billion board feet.

For the most part the winter is passed as second and third instar larvae, although a few
parent adults may survive hibernation and a few larvae may reach the prepupal stage. Activity is resumed in the spring whenever temperatures become sufficiently high, probably about 50 F . A small fraction of the overwintered parent adults may resume egg laying activity in the spring, but usually most of them extend their galleries without ovipositing; very few of them reemerge. Ordinarily by mid-June half the immature stages have pupated (Blackman 1931:14) and by mid-July most have matured. The young adult beetles do not emerge immediately from the brood tree, but enlarge the pupal chamber, often removing sufficient of the inner bark that their excavations join one another. One of these enlarged chambers may contain as many as 50 beetles. The period of flight is concentrated, seldom beginning before 15 July and rarely continuing later than 25 August. In those areas of California where more than one generation occurs each year there may be notable departures from the usual activity cycle. Whether these deviations are the result of genetic or ecological factors is uncertain.

Trees selected for attack by endemic populations of this insect usually are overmature or weakened standing trees larger than 6 inches DBH. Windfalls or cull logs occasionally may provide favorable breeding places (Evenden et al. 1943:7), particularly when the bole is inclined. During epidemics the more vigorous, rapidly growing trees may be preferred (Beal 1939:2), and coniferous host species not belonging to the genus Pinus may be attacked. Under endemic conditions the area of a particular tree attacked by this species may be restricted or forced upward from the base of the bole by such competing species as adjunctus, or downward from upper parts of the bole by brevicomis. Under endemic conditions in a given area the local population may exhibit a strong preference for one-host species even though other acceptable host species may be intermixed. The preferred host in a given area may be ponderosa, lodgepole, limber, western white, or other pine species. In a given area during an epidemic any acceptable host, or sometimes any conifer, may be attacked, and following the epidemic the attacks usually are again confined to the same host species originally
favored. Climatic factors or competition usually reestablish the original conditions. These local races perhaps may indicate the existence of genetic factors that could lead to the formation of distinct species of beetles, but all available data suggests that the present stage of their evolution has not reached the point where geographical races (subspecies) can be recognized.

The attack evidently may follow either of two patterns, depending on the age and vigor of the host tree and on the presence or absence of certain competing species of bark beetles. In mature sugar pine, where aggressive competing species are virtually absent. the attack usually begins in the upper crown; the lower sections of the tree may then be attacked by one or more successive generations over a period of two or more years (Evenden et al. 1943:9). In younger trees of this and other species the attack usually begins at or near the base and extends upward. Compared to other species the attack is concentrated into a relatively short period of time. It coincides with the period of emergence from about 15 July to 25 August, seldom requiring more than five weeks and possibly requiring as little as three or four days during an epidemic. The beetles strike the tree individually, not in dense swarms as some popular accounts of the attack might suggest. According to Blackman (1931:21), the number of entrance tunnels per square foot of bark surface
of a successful attack on an average tree ranges from about four to nine. He also observed that the number of attacks was higher in trees where four to nine trees were killed in a group ( 5.90 per sq ft ) than where only one to four trees were killed in a group (5.23 per sq ft ).

The vertical linear egg galleries usually are almost straight, although occasionally an environmental peculiarity may cause some to wind slightly. They are constructed primarily in the soft inner bark of phloem, continually in contact with the cambium and very lightly scoring the wood.

The diameter of an individual egg gallery is slightly greater than the width of the beetle that constructed it. lts length varies considerably, but evidently it depends more on environmental than on hereditary factors. In lodgepole pine in the Wasatch National Forest in Utah, 35 egg galleries selected at random averaged 32.6 cm and the maximum length was 67.5 cm ; in ponderosae pine on the Dixie National Forest in Utah 34 egg galleries averaged 47.5 cm and the maximum length was 79.0 cm . Both series of measurements were made in drought areas in July 1960. Measurable galleries in ponderosa pine in California and Oregon and in western white pine in Oregon gave comparable results, but were too few in number to provide reliable data. Presumably, the character of galleries observed during a severe epidemic

Fig. 68. Dendroctonus spp., posterior half of left side of pronotum: 1, ponderosae; 2, ieffreyi. (Both photographed at 200 X .)
of this species in the Black Hills area led Hopkins (1909a:112) to assume that a completely different species existed in that area as compared to an endemic Pacific Coast form, which apparently constructed much longer galleries. Actually, under endemic conditions in comparable environments, the eastern, western, northern, and southern populations appear indistinguishable when measurements, bark samples, or photographs of gallery systems are compared.

The initial attack is made by the female, usually in a crevice in the bark. About the time she reaches the cambium tissues where the pitch begins to flow she is joined by the male, who then assists her by pushing the excavated frass out of the entrance hole. Continuation of the egg gallery is performed entirely by the female beetle. After several centimeters of gallery have been cleared and the frass ejected from the entrance hole, the male then packs the frass in the lower regions of the gallery, thereby closing the entrance hole and tightly filling the gallery except for a few centimeters in the area where the beethes are working. It is not uncommon, following mating, for the male to leave the gallery, either before the entrance is blocked or through a ventilation tunnel, in order to join a second female.
From the entrance hole the gallery usually ascends diagonally about $3-5 \mathrm{~cm}$ before turning directly upward. In about half the gallery systems studied this diagonal portion extended to the right of the entrance hole, about a third went to the left, and in the remainder the diagonal portion was absent. This oblique part of the tunnel ordinarily is more irregular in width than the remainder of the egg tunnel and ordinarily is sufficiently wide to permit turning or to act as a nuptial chamber. Ventilation tunnels usually are placed at irregular intervals along the egg gallery but are not always present. Their presence appears to be related to the stage of gallery construction, to the thickness of the bark, and to the activity of the beetles. Evidently they are not constructed until after the entrance has been plugged. In thin-barked lodgepole pine 18 of the 35 galleries measured (see above) included ventilation chambers, and of these 18 only 3 contained more than 2 ventilation tunnels, with the maximum number
being 4 in one gallery. In the relatively thickbarked ponderosa pine 33 of the 35 galleries measured (see above) included ventilation tunnels and only 3 of the 33 included fewer than 5; the maximum number in one gallery was 13.

The initial part of gallery construction progresses rapidly. Oviposition usually begins when the gallery is about $1-2 \mathrm{~cm}$ above the oblique portion, probably about four to five days after the attack. Egg-laying evidently continues until interrupted by cold weather. The eggs are deposited individually in comparatively small niches, although it is not uncommon for two eggs to be in one niche.

Egg niches are comparatively small, each is just large enough to accommodate an egg and a very small amount of specially prepared frass. The niches are both more narrow and shallow than those of the foregoing species. They are distributed in a pattern peculiar to this species and jeffreyi, with alternating groups of one to eight niches placed along the sides next to the cambium. The size and spacing of these groups varies tremendously from gallery to gallery and even within the same gallery, depending upon the prevailing environmental conditions. Ordinarily about half these "groups" consist of one niche each; seldom do they exceed five in number. It is not uncommon for one or two niches to occur opposite one of these groups, a departure from their strictly alternate arrangement. In a third of the galleries studied there were no niches in the upper or last half of the gallery; in an additional one-tenth there were none in the last third. When niches occurred in the terminal regions of the gallery it appeared, in many cases, that the adult female either abandoned the gallery prior to the onset of cold weather or died before or during the winter months, and the usual feeding area at the end of the tumnel was not represented.

Following oviposition the parent beetles may continue the gallery, often ending it in a somewhat irregular feeding tunnel, or they may abandon the gallery to commence a new attack. Evenden (1943:12) estimated that 10 to 30 percent of the parent adults from sugar pine and almost 100 percent of those from western white pine reemerged to begin a second attack. These values appear to be higher
than the estimated reemergence rate observed during this study, but support the observation that there is a greater tendency for
reemergence to occur when the bark of the host tree is either comparatively thin or subject to rapid drying for various other reasons.

Fig. 69. Dendroctonus spp., distribution map: ponderosae, open circles; jeffreyi, closed circles.

The length of the incubation period has not been determined precisely, but has been estimated by various workers to require about 7 to 10 days. The larval mines are continuously in contact with the cambium and are somewhat irregular, but usually their main axis tends to be perpendicular to the egg gallery. Their length varies considerably with the amount of moisture or crowding present. They may be only 1 to 2 cm in length, increasing very slightly in width before reaching the suddenly expanded irregular feeding area where the last two or three instars and pupation are passed, or they may extend 10 to 20 cm and increase substantially in width before the pupal cell is formed. It is not uncommon to find both extremes in the same system of galleries. The larvae may pass the winter in any instar, but apparently second and third instar larvae predominate. Because of overwintering in this stage and because only one generation usually occurs each year, the average length of the larval period is near 300 days. During the latter part of the larval period a pupal cell is cleared of the frass in the enlarged feeding area, still in contact with the cambium. Here the prepupal and pupal stages are passed, the later evidently requiring about two to four weeks for completion. A maturation period of about one month usually follows the pupal stage before emergence occurs.

Notes. - The names ponderosae and monticolae were based on syntypic series. The females referred to by Hopkins (1909a,b) as types of their respective species are here designated as lectotypes of those species as indicated above.

The size of specimens of this species appears to be influenced by the thickness of the phloem of their host and by moisture and temperature factors. Populations from Pacific Coast areas are almost always smaller than 5.0 mm , and those from eastern areas are almost always larger than 5.5 mm in trees with sufficiently thick phloem.

Due to three mixed series and to two series in which the host labels were reversed, all collected in northern California by the same individual, I (Wood 1963) concluded that ponderosae and jeffreyi were synonymous. Whether that mixing and apparent falsification of data was deliberate or accidental has
not been determined. It was detected during my subsequent studies involving several long series of both forms from the area where the supposed intergradation occurred. It is now obvious that both ponderosae and jeffreyi are good species (Lanier and D. L. Wood 1968).

Lanier and D. L. Wood (1968) and others have cited Hay (1956) as establishing the original synonymy of ponderosae and monticolue; however, they overlook the fact that monticolae was named from Pinus monticola, not from $P$. ponderosae or $P$. contorita. The possibility that beetles attacking adjacent stands of $P$. monticola and P. ponderosa were either the same or different species was never investigated by Hay. He hybridized Idaho beetles reared from $P$. ponderosa with others from Utah and Colorado also from P. ponderosa. He did not investigate the fundamental nomenclatural question, although he did contribute important biological data.

The above treatment was based on the lectotypes of ponderosae and monticolae and more than 6000 other specimens.

## 8. Dendroctonus jeffreyi Hopkins Figs. 68. 69

Dendroctonus jeffreyi Hopkins, 1909, L'S. Dept. Agric. Bur. Ent. Tech. Bull. 17(1):114 (Holotype, female; Little Yosemite, California; U.S. Nat. Mus., 7449
Diagnosis.- This species is distinguished with difficulty from ponderosue Hopkins by the smaller pronotal punctures that are separated by spaces averaging at least twice as large as the diameter of a puncture, and, in the area of sympatry, by the larger size (ponderosae specimens from South Dakota to Arizona may average as large as ieffreyi).

Male.- Length 4.6-6.8 mm (average about 6.0 mm ), 2.2 times as long as wide; color black.

Essentially identical to ponderosae except as noted in diagnosis and key.

Female.- Similar to male except epistomal process less well developed and elytral crenulations and granules averaging slightly larger.

Distribution.-S Oregon to N Baja California.
USA: California: Big Bear Lake, Big Bend R. S., Big Pine, Big Springs in Shasta Co., Black's Mt. in Lassen Co.. Butte Lake, Cisco, Cottabe Springs in Calaveras Co., Darrington, Donner Lake. Eiler Lake in Lassen Co..

Fallen Leaf Lake, Hat Creek, Kingvale, Lassen N. P., Old Station in Shasta Co., San Bernardino N. F., Sands Flat, Sequoia N. F., Scaffold Meadows, Shasta N. F., Strawberry in Tuolumne Co., Wolfhorn, Vade, and Yosemite N. P. Oregon: Bly. MEXICO: Baja California: Sierra San Pedra Martir.
Hosts. - Pinus jeffreyi, and very rarely $P$. ponderosa (probably accidental).

Biology.- The galleries and basic habits are as in ponderosae. Eaton (1956) indicates the principal attack occurs in June and July with a lesser peak in late September and October. He reports the volume of standing timber killed by this species as 55 million board feet annually from 1932 to 1951 . One generation per year is normal in the northern part of its range; a partial or complete second generation may occur in southern areas. The attack is directed at the lower half of the bole.

In June 1961, 34 gallery systems averaging 41.7 cm per gallery were measured in Jeffrey pine on the Tahoe National Forest in California. The maximum length was 66.0 cm . These figures agree with those for ponderosae; the number and position of egg niches also appeared to be indistinguishable from ponderosae. Perhaps a more extensive statistical analysis conducted under both endemic and epidemic conditions would reveal significant differences.

The above treatment was based on the holotype and on more than 500 other specimens.

## 9. Dendroctonus parallelocollis Chapuis Figs. 70A,B

Dendroctonus parallelocollis Chapuis, 1869, Synopsis des Scolytides, p. 36 (Holotype, female; Mexico; Brussels Mus.)
Dendroctonus aztccus Wood, 1963, Great Basin Nat. 23:69 (Holotype, male; San Raphael, Mexico, Mexico; Wood Coll.); Wood, 1969. Great Basin Nat. 29:121. Synonymy
Diagnosis.- This species is distinguished from terebrans (Olivier) by the subcylindrical pronotum that lacks a conspicuous anterior constriction, by the more coarsely sculptured elytral disc, and by the distribution.

Male. - Length 4.9-6.3 mm (average about 5.5 mm ), 2.65 times as long as wide; mature body color black.

Frons almost uniformly convex between eyes from vertex to epistomal process with a
small, rather indefinite median impression on lower third well above base of epistomal process; epistomal margin elevated, its surface smooth and shining; epistomal process slightly narrower than half ( 0.44 times) distance between eyes, its lateral margins oblique (about 45 degrees from horizontal) and not at all elevated, horizontal portion slightly more than half its total width, flat, overlapping, and very slightly exceeding epistomal margin and bearing under its distal margin a dense brush of conspicuous yellowish setae; surface rather coarsely, closely, deeply punctured with rather abundant, isolated granules interspersed. Vestiture, in addition to epistomal brush, moderately long, sparse, inconspicuous.

Pronotum 0.80 times as long as wide, widest on basal half; sides weakly arcuate, almost subparallel on basal half, then converging gradually to rather poorly developed transverse constriction just behind broadly, shallowly emarginate anterior margin; surface smooth and shining with moderately small, close, rather deep punctures, becoming rather shallow laterally and very minutely granulate on lateral rim; a median line obscurely indicated anteriorly. Vestiture scanty, becoming more abundant, longer, and rather coarse anteriorly and laterally.

Elytra 2.4 times as long as wide, 2.3 times as long as pronotum; sides straight and subparallel on basal two-thirds, rather broadly rounded behind; basal margins arcuate and bearing a row of nine moderately large, raised, overlapping crenulations, with several smaller submarginal ones particularly on interstriae 2 and 3 ; striae weakly impressed, punctures rather small and moderately deep; interstriae almost twice as wide as striae and armed by abundant, confused, transverse crenulations, each averaging about two-thirds width of an interstriae, a few wider than an interstriae and sometimes crossing striae. Declivity steep, uniformly convex; striae 1 to 3 straight, punctures almost as large as on disc; interstriae 1 to 3 about equal in width and bearing rather abundant, somewhat confused (usually arranged in widely staggered single row), moderately large tubercles. Vestiture much longer and more abundant on declivity, a few setae twice as long as width of an interstriae.

Female.- Similar in all respects to male except pronotum evidently a little more coarsely punctured and the elytra somewhat more coarsely sculptured.

Distribution.- Chihuahua and Sinaloa to Honduras.

AIEXICO: Chihuahua: Garcia-Dublan Road, VII-3I, D. E. Beck. Mexico: San Raphael, 11-1X-49. No. I602S. Pinus leiophylla, J. P. Perry, Jr.. Tlalmanalco, 1, S-I, and 16-IV-50. P. leiophylla, J. P. Perry, Jr. Michoacán: 6 km W Quiroga, 17-IV-65, 2200 m. Pinus, S. L. Wood; 10 km E Volcan Paricutin. 19-V1-65. Pinus, S. L. Wood: Uruapan. 12-VII. Sinaloa: 32 km or 20 miles NE Copala, 22 -Vil-53. Pinus, S. L. Wood. GUATEMALA: "Guatemala." HONDURAS: San Lucas. Paraiso, 22-IN-64, So0 m, P. oocarpa, S. L. Wood: Tegucigalpa, 9-III-64, P. oocarpa, S. L. W'ood: Zamorano. Morazan. IS-IV-64, 700 m, P. oocarpa; S. L. Wood.

Hosts. - Pinus leiophylla and P. oocarpa.
Biology. - The stimps of dying trees larger than 12 inches DBH were attacked near the ground level, with the parental tun-
nels extending upward or downward from that point. The parental gallery systems form a complex crisscross system very similar to approximatus Dietz; however, alternating egg niches are in contact with the cambium and larval mines are exposed on peeled bark.

Notes.- The above treatment was based on the holotypes of parallelocollis and $a z-$ tecus, and on 61 other specimens. It is a rare species that is easily confused in the field with other species.

## 10. Dendroctonus terebrans (Olivier) Figs il. 72

Scolytus terebrans Olivier, 1795, Entomologie ou Histoire Naturelle des Insects, Coleopteres +78 : 6 Syntyper ? Amerique septentrionale; presumably Paris Museum, but not located)
Dendroctomus terebrans: Erichson, 18:36, Archiv Naturgesch. 2(1):53

Fig. 70A. Dendroctonus parallelocollis, head and pronotum of female: 1, anterior; 2, dorsal; 3, lateral.

Diagnosis.- This species is distinguished from the closely related valens LeConte by the black body color, by the much larger punctures on the lateral areas of the pronotum, by the larger, more abundant declivital tubercles, and, in part, by the distribution.

Male. - Length $5.0-7.5 \mathrm{~mm}$ (average about 6.0 mm ), 2.2 times as long as wide; mature body color dark brown to black.

Frons rather evenly convex, with a shallow median impression about a third of distance from upper level of eyes to epistomal margin, very feebly elevated lateral to impression; epistomal margin elevated, its surface smooth and shining; epistomal process broad, about half as wide ( 0.50 times) as distance between eyes, its arms oblique (about 30 degrees from horizontal), elevated only at median angles of arms, horizontal portion about two-thirds its total width and broadly, transversely concave, overlapping and ending just above epistomal margin and bearing under its distal margin a dense brush of yellowish setae. Vestiture, in addition to epistomal brush, moderately long, sparse, inconspicuous.

Pronotum 0.70 times as long as wide, widest at base; sides weakly arcuate and converging very slightly toward moderately
strong constriction just behind broadly, shallowly emarginate anterior margin; surface smooth and shining, punctures moderately large, rather shallow, close, becoming two to three times larger in diameter near lateral margins; bottom or floor of each puncture irregularly reticulate; a partly impunctate, feebly raised median line indicated on posterior two-thirds; vestiture scanty, longer and more evident laterally.

Elytra 1.4 times as long as wide, 2.1 times as long as pronotum; sides straight and subparallel on basal two-thirds, rather broadly rounded behind; basal margins arcuate and bearing a row of about 12 moderately large, raised, overlapping crenulations, with several smaller submarginal ones particularly on interstriae 2 and 3; striae weakly impressed, punctures small and rather shallow; interstriae more than twice as wide as striae and armed by abundant, confused, transverse crenulations each averaging about half width of an interstriae, a few about two-thirds as wide on posterior half of disc. Declivity rather steep, convex; strial punctures slightly smaller than on disc; interstrial punctures confused and all rather coarsely granulate, largest granules forming a somewhat definite

Fig. 70B. Dendroctonus parallelocollis, distribution map.
largest granules forming a somewhat definite median row on each interstriae. Vestiture moderately abundant, longer on declivity, length of longest setae slightly greater than a distance equal to width of an interstriae.

Female.- Similar to male except a median frontal elevation evident at upper level of eyes; epistomal process less well developed; pronotal punctures very slightly larger; discal crenulations and declivital granules a little larger.

Distribution.- E Massachusetts to E Texas and Florida.

USA: Alahama: Auburn. Barton, Calhoun, "DeSoto S. P.." Grand Bay, Mobile, "Redland." Arkansas: Hot Springs, Delaware: "Delaware," District of Columbia: "Taxoma" Florida: Baker Co., Dunedin, Ft. Hosts.- Pinus echinata, P. elliottii, P. palustris, P. rigida, P. serotina, P. strobus, $P$. taeda.

Biology. - This is a secondary enemy of pines, and, less commonly, other coniferous trees; consequently, economic damage attributed to it is slight when compared to some of the other species of Dendroctonus.

Since this species has not been observed by me during the course of this study the following comments are based on personal observations made on two occasions two decades ago, and on the reports of Hopkins (1909b:147) and of Blackman (1922:57).

The principal overwintering stage is the adult, either in the bark of the brood tree or in newly started galleries of a newly attacked host: they may also pass the winter as partly grown larvae. In the spring the adults become active in March or April and either begin or extend their new galleries as the period of oviposition commences. Overwintering larvae complete their development in the spring and evidently emerge from the brood tree prior to mid-July. The period of flight activity evidently continues more or less gradually from March to December. In the southern parts of its range, activity may continue without intermption throughout the year.

Stumps more than four inches in diameter of recently cut trees or of injured or weakened trees are selected for attack. Their galleries ordinarily extend downward into the

Fig. 7I. Dendroctonus terebrans: A, female head; B, female declivity; C, male seminal rod.
roots; occasionally they extend upward as much as two or three feet above the ground level, except in the southwestern parts of its distribution, where they may extend more than 12 ft above the ground (Smith and Lee 1972:5). Frequently the attacks are made in the vicinity of a wound at the base of the tree. Even though such attacks do not kill the host immediately, they may interfere with normal growth and reduce vitality, thereby inviting other insect or disease-causing agents to attack the tree.

The attack ordinarily begins at or just above the ground level, usually with only a few pairs of beetles participating. The female constructs the entrance tunnel and normally is joined by the male shortly after she reaches the cambium. If the amount of pitch encountered is excessive, the gallery usually is extended upward; otherwise it is extended downward after ascending 1 or 2 cm . The egg gallery varies considerably in length, but seldom exceeds 30 cm . It may be linear, slightly wider than the beetle making it, or it may be branched; ordinarily it is irregularly widened at various places. As with other species, the male removes the frass from the working area, ejecting it from the entrance hole at first, then later packing it into the unused areas.

There are no individual egg niches. Groups of eggs are deposited rather loosely at one side of the gallery in one of the widened areas. These groups are then separated from the main areas of the gallery by a rather tightly packed partition of frass.

The periods of incubation and of larval development have not been precisely determined. The larvae do not construct individual tunnels, but work together in the phloem tissues in contact with the cambium, extending the cavity started by the parents. In some instances these cavities are said to cover several square feet of the inner bark (Blackman 1922:58). These extensions by the larvae appear to wander aimlessly, favoring no particular direction. Larvae from eggs laid in the spring evidently pupate by mid-July and emerge in the fall. There is one complete and partial second generation each year in most areas; two complete generations may occur in the extreme southern parts of its range.

Notes.- The above treatment was based on about 300 specimens. The type evidently is in the Paris Museum, but it has not been located.

This species is very similar to valens in anatomical characters and in habits; consequently, much confusion exists in the literature pertaining to the identity of these species (Hopkins 1909b:148). In coastal areas from New Jersey to Massachusetts and, apparently, in the mountains of North Carolina, these species occur in adjacent areas in distinctive habitats without hybridization.

## 11. Dendroctonus valens LeConte <br> Figs. 72, 73, 74

Dendroctonus valens LeConte, 1860, Pacific R. R. Explor. $5(2): 59$ (Holotype, male; San Francisco, California: Mus. Comp. Zool.)
Dendroctonus beckeri Thatcher, 1954, Coleopt. Bull. 8:4 (Holotype, female; Totonicapan, Guatemala; U.S. Nat. Mus.); Wood, 1963, Great Basin Nat. 23:78. Synonymy
Diagnosis.- This species is distinguished from the very closely related terebrans (Olivier) by the reddish brown body color, by the smaller punctures on the lateral areas of the pronotum, by the smaller, less abundant granules on the elytral declivity, and, in part, by the distributions.

Male.- Length 5.3-8.3 mm (average about 7.3 mm ), 2.1 times as long as wide; mature body color uniformly reddish brown.

Frons irregularly convex, with a pair of lateral protuberances about a third of distance below upper margin of eye to epistomal margin, these protuberances separated by a broad, shallow, subconcave impression; epistomal margin elevated, its surface smooth and shining; epistomal process very broad, equaling about two-thirds ( 0.60 times) distance between eyes, its arms oblique (about 20 degrees from horizontal), elevated only at inner angles of arms, horizontal portion about two-thirds its total width, broadly concave, overlapping and ending just above epistomal margin and bearing under its distal margin a dense brush of yellowish setae. Vestiture, in addition to epistomal brush, moderately long, sparse, inconspicuous.

Pronotum 0.73 times as long as wide; sides weakly arcuate, almost subparallel on basal two-thirds, then moderately constricted just
behind broadly, shallowly emarginate anterior margin; surface smooth and shining, punctures very close, rather shallow but sharply impressed, rather small but irregular in size, not larger laterally; an impunctate, sometimes feebly raised median line indicated on posterior three-fourths; vestiture scanty, longer and more evident laterally.

Elytra 1.5 times as long as wide, 2.2 times as long as pronotum; sides straight and subparallel on basal two-thirds, rather broadly rounded behind; basal margins arcuate and bearing a row of about 12 moderately large, raised, overlapping crenulations, with several
smaller submarginal ones particularly on interstriae 2 and 3; striae weakly impressed, punctures rather small and deep; interstriae about one and one-half times as wide as striae and armed by abundant, confused, small, transverse crenulations, each averaging about one-third width of an interstriae, almost never more than half as wide on posterior half of disc. Declivity moderately steep, convex, with a feeble impression between striae 1 and 3 ; strial punctures slightly smaller than on dise; interstrial punctures confused and finely to coarsely granulate, largest granules forming an indefinite median row (in a few males

Fig. 72. Dendroctonus spp., distribution map: terchrans, open squares; talens, open circles.
only this median row of granules represented). Vestiture moderately abundant, longer on declivity; longest setae slightly exceed a distance equal to width of an interstriae.

Female. - Similar to male except a rounded median frontal elevation evident at
upper level of eyes; pronotal punctures very slightly larger; and discal crenulations and declivital granules a little larger.

Distribution.- Northwest Territories and Nova Scotia to Honduras, except not in SE USA.

Hosts.- Pinus contorta, P. coulteri, P. echinata, P. edulis, P. hartwegii, P. jeffreyi, $P$. lambertiana, P. lawsonii, P. leiophylla, P. monticola, P. murrayana, P. oocarpa, P. ponderosa, P. pseudostrobus, P. radiata, P. resinosa, $P$. rigida, $P$. sabiniana, $P$. syluestris, $P$. strobiformis, $P$. strobus, $P$. tenuifolia, and $P$. virginiana Abies concolor, Larix laricina, Picea glauca, P. excelsa, and P. rubens.

Biology.- In general, this is a secondary enemy of pine and spruce, but on occasion it attacks and kills apparently healthy trees. It usually works in conjunction with other more aggressive species and. consequently, comparatively little economic loss is attributed to it.

Fig. 73 continued. F, egg galleries.

This species may overwinter either as young or mature adults or as partly grown larvae. There is an extreme overlapping of generations, which is reflected by these insects being seen in flight any month of the year during their period of activity. In the northern parts of its range this period of activity evidently is from May to October; in the southern areas the species is active throughout the year.

Ordinarily stumps and injured, weakened, or dying trees larger than 20 cm DBH are selected for attack, although in some areas apparently healthy trees may be selected. The attack usually is concentrated at or near the ground level at the base of the tree, but in some areas it may extend 6 or more ft above the level of the ground. Generally this species arrives quite some time after other species have attacked a particular tree.

The attack on any one tree ordinarily involves only a few pairs of this species. It usually begins a few centimeters above the ground level then progresses above and below the point. It is not concentrated and, in fact, may involve two or more successive generations before the host succumbs.

The egg galleries of this species are exceedingly variable. The female, as with other species in the genus, constructs the entrance tunnel. After reaching the cambium region the tunnel extends upward for a short distance. If the amount of pitch encountered is excessive, it may continue upward; if not, it may curve downward into the roots. The egg gallery may be linear, slightly wider than the length of the beetle constructing it, or it may be branched or of a broad, irregular cave type. The linear pattern is more common in warmer parts of the range. ln southern Mexico, Guatemala, and Honduras egg galleries exceeding 40 cm in length were common; however, it should be mentioned that broad cave-type excavations were found in the same tree with linear galleries, as were all degrees of intergradation between these extremes. Usually one side of the gallery is expanded somewhat, either continuously or irregularly, for deposition of the eggs.

Oviposition in most areas of the United States evidently begins in late May or early June and continues throughout the warm months. Egg-laying in northern or southern
areas might begin earlier or later than this. The eggs are deposited along the far side of the expanded parts of the gallery, away from the main area of activity, either loosely packed in frass or in layers, in groups of 10 to 40 or more. They are then covered with a more or less compact layer or partition of frass. There are no individual egg niches.

According to Swaine (1914:20) the larvae hatch in about 10 days. They do not construct individual tunnels but mine in congress in the phloem next to the cambium in a general direction away from the egg gallery. Behind them the large flat cavity is filled by a reddish frass. The length of the larval period has not been determined precisely, but probably exceeds two months; it is suspected that in northern areas it may exceed a year. Pupal cells generally are formed in the frass, although occasionally a larva will construct a short individual tunnel in the phloem adjoining the common cavity where the pupal cell is formed. In the southern parts of its distribution there is one complete and at least a

Fig. 74. Dendroctonus valens: A, eggs; B, larva; C, pupa; D, adult. (After Smith 1971:5.)
partial second generation each year; in northern areas a generation evidently may require more than one year.

Notes.- The above treatment was based on the holotypes of valens and beckeri and on more than 3000 other specimens. Specimens emerging from crowded or unusually dry, hot environments frequently are abnormally small, pale, and occasionally abnormal in surface features. Those from the northeastern parts of the range may be strikingly different from specimens originating from California or from Central America. The synonym beckeri was named from unusually dark specimens. Vité (pers. comm.) suggested that data from pheromone tests indicate culens could be a composite of several species. Additional studies are needed to clarify this problem.

## 12. Dendroctonus rhizophagus Thomas \& Bright

Dendroctonus rhizophagus Thomas \& Bright, 1970. Canadian Ent. 102:479 (Holotype, male; 16 km or 10 miles SW El Salto, Durango, Mexico; Canadian Nat. Coll.)
Dlagnosis.- Biologically, this species is distinct from ralens LeConte; anatomically, they intergrade to such an extent that separation is difficult. Although the characters are not absolute, they may be distinguished as described below. These comparisons were based on specimens from El Salto, Durango, for both species.

Male.- Length 5.0-6.3 mm, 2.1 times as long as wide; color dark reddish brown, elytra of fully mature individuals almost always lighter in color.

Frons about as in valens except subcrenulate granules almost never present, sparse and much finer when present.

Pronotum about as in calens except punctures tending to be less uniform in size, those on basal half separated by distances averaging greater than diameter of a puncture (about half this distance in valens), middle third with a few very large punctures interspersed with others; median line more broadly impunctate and moderately to acutely carinate at least on basal half (feebly, if at all elevated in valens).

Elytra as in valens except strial punctures tending to be larger, especially on declivity,
and interstrial crenulations tending to be smaller.

Female.- Similar to male, with frons resembling female valens except median summit at upper level of eves forming a more definite, subacutely elevated, longitudinal carina, its crest impunctate (more broadly rounded and with median line randomly punctured in valens).

Distribution.- Chihuahua to Durango.
MEAICO: Chihuahua: San Juanito (David Cibrián and M. M. Furniss, pers. comm.); Mesa del Huracan, 24-VII-64, Pinus engelmannii, J. B. Thomas. Durango: 16 km W El Salto, 15-V'll-64, P. durangensis, J. B. Thomas.

Hosts.-Pinus durangensis, $P$. engelmannii, $P$. spp.

Biology.- Seedlings as small as 2 cm in basal diameter to poles 8 cm DBH are attacked near or below the surface of the ground. Two generations per year occur in the same area where calens has only one generation per year. Parental galleries tend to be more linear than calens and there are differences in egg deposition and larval mines (Cibrián and Furniss, pers. comm.). A detailed treatment of these differences will be described later by these authors.

Notes. - The above treatment was based on the type series and on several other specimens. This species was treated by me as valens until the biological differences became known.

## 13. Dendroctonus punctatus LeConte Figs. 75, 76

Dendroctonus punctatus LeConte, 1868. Trans. Amer. Ent. Soc. 2:173 (Holotype, female; northern New York; Mus. Comp. Zool.)
Dendroctonus johanseni Swaine, 1919, Canadian Arctic Exped. Rept. 1913-1918, 3(E):5 (Holotype, female?; Sandstone Rapids, Coppermine River, Northwest Territories; Canadian Nat. Coll, 9248); Wood. 1963, Great Basin Nat. 23:86. Synonymy
Diagnosis.- This species is distinguished from murrayanae Hopkins and rufipennis (Kirby) by the uniformly brown color, by the smooth, polished frons, which is deeply punctured but entirely devoid of granules, and by the much larger punctures of the elytral declivity. It is almost identical with the Eurasian micans (Kugelann).

Male. - Length 5.4-6.8 mm (average about 6 mm ), 2.41 times as long as wide; body color uniformly brown to dark brown.

Frons convex, protruding very slightly at center just below middle; epistomal margin elevated, smooth, shining; epistomal process a third ( 0.32 times) as wide as distance between eyes, its arms strongly oblique (about 55 degrees from horizontal) and slightly elevated, horizontal portion about two-thirds its total width, shallowly concave, overlapping and ending just above epistomal margin and bearing under its distal margin a dense brush of yellowish setae; surface smooth and shining from vertex to epistoma, punctures,
rather close, deep, coarse, sharp, interspersed with very few minute punctures, with no indication of granules or tubercles. Vestiture fine, long, inconspicuous, rather sparse.

Pronoturn 0.71 times as wide as long, widest at base, sides weakly arcuate and converging toward rather strong constriction just behind broadly, shallowly emarginate anterior margin; surface smooth and shining, punctures rather fine but irregular, close, deep, with a few very minute points interspersed; median line impunctate posteriorly;

Fig. 75. Dendroctonus spp.: A, punctatus, head; B, murrayanae, head; C, murrayanae, seminal rod; D, murrayanat, gatleries.
vestiture moderately abundant, fine and rather short on disc, longer and coarse laterally.

Elytra 2.5 times as long as pronotum; sides straight and subparallel on basal two-thirds, rather broadly rounded behind; basal margins arcuate and bearing a row of about 12 moderately large, raised, overlapping crenulations, with several smaller submarginal ones particularly on interstriae 2 and 3; striae weakly impressed, punctures large and rather deep; interstriae about one and one-half times as wide as striae and armed by rather abundant confused, small, transverse crenulations, each averaging about one-fourth width of an interstriae, never more than a third as wide on posterior half of disc. Declivity rather steep, convex, with sutural interstriae slightly elevated; strial punctures almost as large as on disc; interstriae smooth, with numerous confused punctures less than onethird as large as those of striae, about a third of them minutely granulate on their upper rims. Vestiture rather long and abundant; slightly longer on declivity, longest setae about one and one-half times as long as width of an interstriae.

Female.- So very similar to male that sexes recognized only with difficulty; female very slightly more coarsely sculptured, particularly declivital granules very slightly larger.

Distribution.- Alaska to New York and West Virginia.

ALASKA: Bonanza Ck. near Fairbanks, Circle, Haines Rd. (mile 27), Rampart House, Savonoski. CANADA: AIberta: Cypress Hills, Nckenzie Highway (25th baseline). Northwest Territories: Aklavik, Ft. Smith, Sandstone Rapids of the Coppermine River. Ontario: Frater. Yukon: Alaska Highway (mile 1152), Carcross, Carmaks (mile 8, Mayo Rd.), Rampart House, Watson Lake, Whitehorse, Wolf Ck. USA: New York: "N. Y." Pennsylvania: Mt. Alto. West Virginia: Randolph Co.

Hosts.-Picea glauca, P. rubens, $P$. sitchensis.

Biology.- This species evidently is rare in forests accessible to commercial logging; consequently, it is not presently recognized by forest interests as an important species. Structurally and (apparently) biologically it is so similar to rufipennis that field observers usually do not distinguish it from that species.

It is known to infest the lower bole and stumps of spruce from West Virginia to

Alaska. Structurally it is almost indistinguishable from micans and is very similar to murrayanae; therefore, it is presumed that its biology is equally similar to these species. Collectors who took punctatus in two different areas of northern Canada and in Alaska suspected that at least two years were required to complete the life cycle in those areas; one year evidently is sufficient in the Great Lakes area and in the eastern United States.

Notes.- The above treatment was based on the holotypes of punctatus and johanseni, and on about 250 other specimens. It is a geographical replacement of the Eurasian micans that is distinguishable only by means of minute characters. Because the reduction of these forms to the level of subspecies would serve no useful purpose and tend to confuse the literature relating to them, both are treated here as valid species.

## 14. Dendroctonus murrayanae Hopkins Figs. 75,76

Dendroctonus murrayanae Hopkins, 1909, U.S. Dept. Agric. Bur. Ent. Tech. Bull. 17(1):140 (Holotype, female: Keystone, Wyoming; U.S. Nat. Mus., 7454)

Dendroctonus rufipennis: Hopkins, 1909 (nec. Kirby, 18:37), U.S. Dept. Agric. Bur. Ent. Tech. Bull. 17(1):135: Wood. 1963, Great Basin Nat. 23:88. Misidentification corrected
Diagnosis. - This species is very closely allied to punctatus LeConte and rufipennis (Kirby) and is distinguished from them with considerable difficulty. From punctatus it differs by the more closely punctured, sparsely granulate frons, by the more coarsely punctured pronotum, by the subequal size of strial and interstrial punctures of the declivity, by the reddish brown elytra with dark brown pronotum, and by the hosts. From rufipennis it differs by the distinctly punctured, finely, more sparsely granulate frons, by the male genitalia, by the galleries, and by the hosts.

Male. Length 5.0-7.3 mm (average about 6 mm ), 2.3 times as long as wide; body color dark brown, with reddish brown elytra.

Frons convex, protruding slightly on lower half; epistomal margin elevated, smooth, shining, epistomal process a third ( 0.32 times) as wide as distance between eves, its arms strongly oblique (about 55 degrees from the
horizontal) and moderately elevated, horizontal portion about two-thirds its total width, shallowly concave, overlapping and ending just above epistomal margin and bearing under its distal margin a dense brush of yellowish setae; surface shining from vertex to epistoma, punctures very close, deep, coarse, about half of them with a small rounded granule on median or lower rim (usually). Vestiture fine, long, inconspicuous, rather sparse.

Pronotum 0.74 times as long as wide, widest at base; sides weakly arcuate and converging toward rather strong constriction just behind broadly, shallowly emarginate anterior margin; surface smooth and shining, punctures rather fine, but irregular, close, deep; median line impunctate posteriorly. Vestiture moderately abundant, fine, and rather short on disc, longer and coarse laterally.

Elytra 2.4 times as long as pronotum; sides straight and subparallel on basal two-thirds,
rather broadly rounded behind; basal margins arcuate and bearing a row of about 12 moderately large, raised, overlapping crenulations, with several submarginal ones particularly on interstriae 2 and 3; striae very weakly impressed, punctures rather large and deep, usually decreasing in size toward base; interstriae slightly more than one and onehalf times as wide as striae and armed by rather abundant, confused, small crenulations, each averaging about one-fourth width of an interstriae, never more than half as wide on posterior half of disc. Declivity rather steep, convex, with sutural interstriae slightly elevated; striae impressed, punctures half as large as on disc, usually three times as large as those on interstriae (except in a few examples having unusually large interstrial punctures); interstriae almost smooth, subshining, punctures rather abundant, confused (very irregularly three-ranked), median series very finely granulate on upper rims. Vestiture rather long and abundant; slightly longer

Fig. 76. Dendroctonus spp., distribution map: punetatus, solid squares; murrayanae, open circles.
on declivity, longest setae about one and onehalf times as long as width of an interstriae.

Female.- Very similar to male except arms of epistomal process less strongly elevated and declivital granules distinctly larger.

Distribution.- British Columbia and Ontario to Utah, Colorado, Minnesota, and Michigan.

CANADA: Alberta: Banff, Cypress Hills, Edmonton, Hillsdale, Jasper N. P., Lake Louise. British Columbia: Stanley, Wycliff. Manitoba: Clear Lake Trail in Riding Mts. Ontario: Black Sturgeon Lake. Frater. USA: Colorado: Jefferson, Kenosha Pass, Wheeler Basin. Idaho: Targhee N. F. Michigan: Grand Island, Whitefish Point. Minnesota: International Falls. Montana: Wisdom. Utah: Logan Canyon, Wolf Ck. Pass. Wyoming: Bighorn Basin, Dubois, "Homestake," Kevstone, Saratoga, Shothone N. F.

Hosts.- Pinus banksiana, P. contorta, and P. strobus.

Brology.- Ordinarily this is not an aggressive species, although available data indicate that it has contributed to bark beetle epidemics more commonly than published data would suggest, and that it has killed healthy, vigorous lodgepole pine. Because of the close superficial resemblance to rufipennis some losses actually caused by this species have been attributed to the destructive spruce beetle that supposedly infested lodgepole pine. In all cases where specimens were preserved for study the "spruce" beetles infesting lodgepole pine actually were this species.

The overwintering young and old adults and larvae in all stages of development became active when subcortical spring temperatures became sufficiently high, probably about 45 to 50 F . Flight activity probably does not begin before June at the high altitudes in Utah where lodgepole pine grows. The earliest attacks observed during this study were found in the second week of July. Because of overlapping generations it is suspected that attacks probably continue from late June to early September.

Stumps, windfalls, and overmature or weakened trees larger than about 8 inches DBH are selected for attack by this species. Trees dying from the attacks of ponderosae apparently provide a favorite breeding place. In standing trees the area under attack seldom extends higher than about 60 cm above the level of the ground; in addition, it usually
extends downward into the roots. In prostrate trees the lower side of the bole is preferred.

The attack evidently begins at or near the ground level at one side of the tree and progresses upward, downward, or around the tree from that point. At times two or more successive generations may be involved in progressively girdling a living tree. Ordinarily only a few pairs of beetles are involved in the attack on a particular tree.

The egg galleries are irregularly vertical, slightly wider than the beetle making them, with two or three irregular but shallow expanded areas along one or both sides; often short branch galleries may also be present. The galleries observed during this study averaged about 12 cm in length; the longest ones were 20 cm in length; they were constructed entirely by the female. As with other species, they were excavated in the phloem in contact with the cambium. In a number of instances it was observed that the female excavated the complete egg gallery before the male appeared; evidently this is not a normal habit. In such instances there were no eggs or larvae in the gallery. When the male was present the lower part of the gallery was packed with frass, thereby closing the entrance hole. Copulation was observed twice; in both instances it occurred near the middle of the gallery in one of the expanded areas.
In the Wasatch National Forest in Utah eggs were found during 1960 from 12 July to 9 September; it was not determined whether or not these were the first or last eggs of the season. The eggs are deposited in the expanded areas in groups of about 20 to 50 or more. A more or less loose covering or partition of frass separates them from the main parts of the egg gallery. In the galleries observed, from one to three such groups occurred in each gallery. Hatching time varied considerably with the season, but probably averaged about 10 days in the galleries studied. There were no individual egg niches in any of the galleries. Evidently a female may reemerge to construct a second set of galleries; this is supported by the fact that in September about a fourth of the galleries studied contained only the female; there were no adults present in an additional fourth.

The larvae feed in congress in a general transverse direction away from the egg gallery. About 6 to 10 cm from the egg gallery the excavated area turns either upward or downward and continues in that direction for an additional 20 to 30 cm or more. It appears characteristic of this species, just before or just after the vertical turn is made, for a few small groups of larvae to become separated from the main body of larvae and mine independently for short distances before rejoining them. This leaves irregular islands of unexcavated phloem in the general cavity. When near maturity, several of the larvae may construct short independent mines where pupations occurs; however, most of the pupal cells occur in the frass of the principal larval excavation. It appeared that the eggs laid in early July were represented by third and fourth instar larvae in September and probably did not mature until the following June; eggs laid in September evidently matured the following July. Evidently there may be one complete and a partial second generation each year in Utah. In the northern parts of the distribution it is possible that less than one complete generation occurs each year.

Notes. - The above treatment was based on the holotype and on 425 other specimens. Various reports (Massey and Wygant 1954) have indicated that during epidemics of rufipemnis lodgepole pine has been killed by that species. An effort was made to locate and examine all voucher specimens on which those reports were based. In every case I investigated those specimens proved to be of murrayanae. Apparently all lodgepole pine allegedly killed by rufipemis actually was killed by this species.

Minute differences in size and punctation on the elytral declivity are evident between eastern and western parts of the distribution (Wood 1963:90). Based upon specimens and other data at hand, I do not consider these features sufficiently important to justify the recognition of separate races.

## 15. Dendroctonus rufipennis (Kirby) Figs. 77. 78, 79

Hylurgus rufipennis Kirby, 1837, in Richardson, Fauna Boreali Imericana $4: 195$ (two syntypes, female; Boreal North America; British Mus. Nat. Hist.)
Dendroctonus rufipennis: LeConte, 1868. Trans. American Ent. Soc. 2:173

Hylurgus obesus Mannerheim, 1843, Moskov. Obshch. 1.sp. Prirody. Otd. Biol. Biul. (Bull. Soc. Imp. Nat. Moscou) 16:296 (Holotype, female; Sitka Island, Alaska; Univ. Zool. Mus., Helsinki); Wood, 1963, Creat Basin Nat. 23:93. Symonymy
Dendroctonus similis LeConte, 1860, Pacific R. R. Explor. 5(2):59 (Lectotype, female?; Oregon; Mus. Comp. Zool., present designation); LeConte. 1868. Trans. Ainerican Ent. Soc. 2:173. Synonymy
Dendroctonus pireaperda Hopkins, 1901, U.S. Dept. Agric. Div. Ent. Bull. 2S:16 (Neotype, female: Camp Caribou, Maine; U.S. Nat. Mus., 7451. present designation); Wood, 1963, Great Basin Nat. 23:94. Synonymy
Dendroctonus engelmanni Hopkins, 1909, U.S. Dept. Agric. Bur. Ent. Tech. Buil. 17(1):130 (Holotype, female; Capitan, New Mexico; U.S. Nat. Mus. 7452); Wood, 1963, Great Basin Nat. 23:95. Synonymy
Dendroctonus borealis Hopkins, I909, U.S. Dept. Agric. Bur. Ent. Tech. Bull. 17(1):133 (Holotype, female; Eagle, Alaska: U.S. Nat. Mus., 7453); Wood, 1963, Great Basin Nat. 23:96. Symonymy
Diagnosis.- This species is distinguished from the very closely related murrayanae Hopkins, with great difficulty, by the more coarsely, more closely granulate frons, by the distinctive male genitalia, by the galleries, and by the host.

Male. - Length 4.4-7.0 mm (average about 5.5 mm ), 2.3 times as long as wide; mature body color very dark brown with reddish brown elytra, old adults usually uniformly black.

Frons convex, protruding slightly on lower half; epistomal margin elevated, smooth, shining; epistomal process a third ( 0.35 times) as wide as distance between eyes, its arms rather strongly oblique (about 45 degrees from horizontal) and moderately elevated, horizontal portion almost two-thirds its total width, shallowly concave, overlapping and ending just above epistomal margin and bearing under its distal margin a dense brush of yellowish setae; surface shining, punctures very close, deep, rather fine, largely obliterated in central area by fine, abundant granules, at least one or two gramules for each puncture in central area, less numerous in surrounding areas. Vestiture fine, long, inconspicuous, rather sparse.

Pronotum 0.71 times as long as wide, widest at base; sides weakly arcuate and converging toward rather strong constriction just behind broadly, shallowly emarginate anterior margin; surface smooth and shining,
punctures rather fine but irregular in size, close, deep; median line impunctate posteriorly. Vestiture moderately abundant, fine and rather short on disc, longer and coarse laterally.

Elytra 2.4 times as long as pronotum; sides straight and subparallel on basal two-thirds, rather broadly rounded behind; basal margins
arcuate and bearing a row of about 12 moderately large, raised, overlapping crenulations, with several smaller submarginal ones particularly on interstriae 2 and 3; striae very weakly impressed, punctures rather large and shallow, usually decreasing slightly in size toward base; interstriae slightly more than one and one-half times as wide as striae and

Fig. 77. Dendroctonus rufipennis: A, female head: B, male seminal rod; C, galleries.
armed by rather abundant confused, small, transverse crenulations, each averaging about one-fourth width of an interstriae, never more than a third as wide on posterior half of disc. Declivity rather steep, convex, with sutural interstriae slightly elevated; striae usually not impressed, punctures minute, subequal in size to and often confused with those of interstriae; interstriae almost smooth, subshining, punctures rather numerous, confused, median series on each interstriae very minutely granulate on upper rims. Vestiture rather long and abundant; slightly longer on declivity, longest setae about one and onehalf times as long as width of an interstriae.

Female. - Very similar to male except arms of epistomal process less strongly elevated and declivital striae usually weakly impressed, with interstrial granules rather large and usually pointed.

Distribution.- Alaska and Newfoundland to Arizona, New Mexico, Michigan, and Pennsylvania.

Hosts.-All species of Picea within its range.

Biology. - This is the most destructive of the spruce-inhabiting bark beetles. It is responsible for killing an estimated average of approximately .33 to .50 billion board feet of standing spruce timber each year. It is also reported to have inflicted substantial losses of lodgepole pine (Massy and Wygant 1954:1). but this was not substantiated by my examination of the beetles collected from the infested trees (see murrayanae, above).

The life cycle of the spruce beetle is complicated by an apparently unique habit of
adult hibernation that contributes toward adapting this species to cold habitats. It may overwinter in any stage of development, but adults and half-grown larvae predominate. A one-year life cycle is more common in southern and warmer sites; a two-year cycle is the most common habit, but a three-year cycle is more common throughout the range of the species than is the one-year cycle; and a fouryear cycle may be possible at very cold sites (Schmid and Frye 1977:4). Local climatic factors or peculiarities of a given season may accelerate or delay development.

In a typical two-year cycle, activity may begin as early as May when subcortical temperatures reach about 45 to 50 F . Flight activity of second-year (breeding) adults may begin in late May, but usually it occurs in June and July.

Under endemic conditions the trees selected for attack consist of windfalls or other prostrate dying green trees or of overmature
or weakened standing trees larger than about eight inches DBH. During an epidemic almost any spruce tree in the stand may be selected regardless of size or vigor. The attack usually begins on the lower third of the bole, except for the first two or three feet above the ground. It ordinarily progresses to include the upper bole and stump later in the season. In prostrate trees only the lower half next to the ground is attacked. The upper bole smaller than eight inches in diameter and limbs generally not subject to attack by this species. The attack is slow and continuous, without any sudden or concerted swarming of the beetles; its duration may vary from a few days to many months, depending on the population density of beetles in the area, upon the resistance of the host, or upon climatic or other ecological factors peculiar to the season or locality. The number of attacks per square foot of bark surface may be as high as 24 , but averages between 6

Fig. 79. Dendroctonus rufipennis, distribution map.
and 9 ; the density of the attacks evidently is greater at the base of the tree and gradually decreases upward (Massey and Wygant 1954:13).

The egg galleries are constructed by the female beetle mostly in the phloem tissues. but they engrave the wood more deeply than other species of Dendroctonus; the thinness of spruce bark may have some bearing on this habit. The egg galleries are parallel to the grain of the wood, almost straight, ordinarily with the lower 1 or 2 cm next to the entrance hole hooked diagonally to either the right or left. The average length of 13 cm and the maximum length of 23 cm for egg galleries observed during this study, made in 1960 in the Wasatch National Forest of Utah, agree with that reported by Massey and Wygant (1954:13). The egg galleries are slightly wider than the width of the beetle making them and, in addition, there usually is an egg groove along the side next to the cambium about $1-2 \mathrm{~cm}$ deep. Ventilation tumnels are placed at irregular intervals, but are not always present.

Oviposition evidently begins less than a week after the attack; there is some question as to its duration because most of the beetles reemerge to construct a second or third set of galleries. Massey and Wygant (1954:15) reported a maximum of 144 eggs in one gallery; they also reported that there was an average of 20.5 eggs per inch of gallery (excluding the diagonal first inch). In the present study it was found that the number of eggs per inch of gallery where eggs occurred was equal to that found by Massey and Wygant, but this rate of deposition was seldom maintained for more than a third the length of the gallery. The largest number of eggs counted in one gallery during this study was 53 in an area where a small epidemic was begimning on the Wasatch National Forest.

There is considerable variation in the way eggs are deposited. In some galleries all or part of the eggs are placed individually in separate niches. These niches may be lengthened sufficiently to accommodate two or more eggs, or extended into elongate grooves as much as 8 cm in length. The niches, or the more typical grooves, ordinarily are placed alternately on the sides of the egg tumnel in
contact with the cambium. Ordinarily, individual niches are formed when the gallery enters a moderately unfavorable environment. Each egg or group of eggs is covered by a layer or partition of frass that separates them from the main gallery.

Following oviposition the gallery may be extended a short distance in an irregular feeding tunnel. When both parents are represented, separate feeding tunnels may give the gallery a characteristic Y-shaped ending. Evidently most of the beetles reemerge to form a second or third set of galleries. Reemerging beetles may extend the flight and oviposition periods beyond the July date indicated above.

At the high altitudes where this species occurs in Colorado, incubation is thought to require three to four weeks (Massey and Wygant 1954:16); it probably takes much less time in Pacific Coast areas, where suitable hosts enable this species to live at or near sea level. The newly hatched larvae feed in the phloem in contact with the cambium, either individually or in groups, in a general direction at right angles away from the egg gallery. Ordinarily, communal feeding is the rule during the second instar. When about one-third grown, all larvae form separate feeding tunnels that wind throughout the phloem, frequently crossing one another. Some larvae that hatch from the first eggs deposited in June may become callow adults by late August to October; however most of them overwinter as larvae and complete their development the following spring or summer. Pupal cells are formed at the ends of the larval mines or in frass of a previously excavated area, either next to the cambium or entirely in the bark. The pupal period in the late spring or early summer may be completed in about 10 to 15 days (Massey and Wygant 1954:17); however, completion of this stage may be extended if pupation begins in the late fall. A normal life cycle requires one year at low elevations on favorable sites or two years at higher, colder sites. Under unfavorable conditions three or even four years may be required to complete a life cycle (Schmid 1977).

The low temperatures that prevail throughout much of the year in many areas
where this species occurs may have a profound effect on the length of the life cycle of this insect. Collectors who took it in the McKenzie River area in northern Canada and in north central Alaska estimated that at least two years were required for larval development.

In the two-year cycle, newly transformed first-vear adults (those hatched the previous year) emerge from standing trees primarily in August and September and move to the previously uninfested base of the brood tree, where they reenter the bark and overwinter in feeding tunnels. They reemerge the following summer as breeding adults. First-year adults in prostrate trees remain in their brood tumnels, without emerging, through their second winter. This habit normally places the overwintering beetles below the snow line, where they are protected from the extremely low winter temperatures that characterize their habitat. Schmid (1977:4) indicates that a varying percentage (from 3 to 88 percent) of the beetles in a given generation at a particular site may exhibit this hibernation habit.

The existence of a three-vear life cvcle has been suggested (Wygant 1954, Schmid 1977). but has not been fully documented. If it does occur, it is apparently achieved by prolongation of the larval period.

Notes. - The above treatment was based on the holotypes of rufipennis, obesus, engelmamni, and borealis, on the known syntypes of similis, and on the neotype of piccaperda. The syntype of similis in the LeConte collection labeled "type" is here designated as the lectotype of that species; the female specimen labeled type no. 7451 in the U.S. National Museum and referred to as the type by Hopkins (1909a:126) is here designated as the neotype of piccaperda. Because this specimen was collected in 1902, it could not possibly have been a syntype. In addition to these types more than 6,000 other specimens were examined.

## 16. Dendroctonus simplex LeConte

 Figs. 80. 81Dendroctonus simplex LeConte, 1865. Trans. American Ent. Soc. 2:173 (Lectotype, male: Canada: Mus. Comp. Zool., present designation)
Diagnosis.- This species is distinguished from the closely related pseudotsugae

Hopkins by the much smaller size, by the less strongly protuberant, smoother, but more coarsely punctured frons, by the more coarsely punctured pronotum, by the larger punctures on the declivital interstriae, and by the distribution.

Male.- Length 3.4-5.0 mm (average about 4.2 mm ), 2.4 times as long as wide; mature body color dark brown, elytra often with a reddish cast.

Frons broadly convex, protruding somewhat on lower half, inflated area arising abruptly just above smooth, elevated rim of epistomal margin; epistomal process less than a third ( 0.30 times) as wide as distance between eyes, its arms very strongly oblique (about 80 degrees from horizontal) and usually not elevated, horizontal portion about three-fourths its total width, flat, overlapping and apparently flush with epistomal margin (actually ending just above slightly extended margin), and bearing under its distal margin a dense brush of yellowish setae; surface shining, smooth, with rather coarse, deep, very close punctures and a very few minute granules. Vestiture sparse, rather short, fine, inconspicuous.

Pronotum 0.71 times as long as wide; widest at base, sides weakly arcuate and converging toward the rather strong constriction just behind broadly, shallowly emarginate anterior margin: surface smooth and shining, punctures rather coarse, irregular in size, close, deep; median line narrowly impunctate posteriorly. Vestiture moderately abundant, fine and rather short on dise, longer and coarse laterally.

Elytra 2.5 times as long as pronotum; sides straight and subparallel on basal two-thirds, rather broadly rounded behind; basal margins arcuate and bearing a row of about 10 rather

Fig. So. Dendroctonus simplex: A. male frons; B, male seminal rod.
large, raised, overlapping crenulations, with several smaller submarginal ones particularly on interstriae 2 and 3; striae weakly impressed, punctures rather large and deep, usually decreasing slightly in size toward base; interstriae less than one and one-half times as wide as striae and armed by an irregular row of transverse crenulations, each averaging about one-third width of an interstriae, a few half as wide on posterior half of disc, a few fine punctures interspersed with crenulations. Declivity rather steep, convex, with sutural interstriae very strongly elevated and interstriae 2 weakly impressed; striae rather deeply, narrowly impressed, punctures greatly reduced; interstrial punctures rather coarse, numerous and confused on 1 , uniseriate on 2 and 3 ; none of punctures granulate.

Vestiture rather coarse, slightly longer on declivity, longest setae equal in length to about one and one-half times width of an interstriae.

Female.- Very similar to male except declivital interstriae with minute confused punctures and each with a median row of coarse, somewhat pointed tubercles, tubercles spaced by a distance slightly less than width of an interstriae.

Distribution.- Alaska and Newfoundland to NE British Columbia, Minnesota, and West Virginia.

ALASK A: College, Fairbanks, McGrath. CANADA: Alberta: Bilby, Edmonton. Mitsue, Smith. British Columbia: Wildmare Ck. New Brunswick: Fredericton, Nictor Lake. Newfoundland: "New Fomdland." Nova Scotia: Sydnev. Ontario: Deili, Pine Springs, Wooler. Quebec: Gaspé, Natashquan, Ungara Bay. USA: Maine:

Minnesota: Carlton Co., Hennepin Co., Itasca St. Pk., Lake Itasca, Mille Lacs Co., Pine River, St. Paul. New Hampshire: Pittsburg, West Stewartstown. New York: Erie Co. West Virginia: Cranesville.
Hosts.- Larix laricina.
Biology.- This species prefers dying or injured trees and, consequently, is not generally regarded as having major economic importance. However, it is known to have successfully attacked and killed healthy mature larch trees.

This species was not observed during this study; all comments that follow are based on Hopkins (1909b:103-106), Simpson (1929:274-279), and Prebble (1933:146). The galleries illustrated by Hopkins for this species are used as the basis for the qualified description of the galleries below. Because the placement of eggs in his figure lacks detail and the system appears to resemble that of the very closely related pseudotsugae, and because of the general phyletic position of simplex in the genus, it is presumed that egg grooves, not niches as illustrated, would normally be constructed by this species.

The principal overwintering stage is the young adult in the brood gallery, although it is not uncommon for some larvae to overwinter. Flight activity begins early in May and continues at a relatively low level until late August; the period of greatest activity apparently is from the last week of May to the second week of June. Adult beetles may reemerge to construct a second or third set of galleries during the season, but none of their progeny leave the brood tree until the following spring.

Trees selected for attack include windfalls, snow breaks, stumps, or other weakened or severely damaged material. The exact pattern of the attack and details of the galleries and habits have not been reported.

Hopkins (1909b:103) indicated that the galleries are vertical and slightly sinuate. Evidently they average about 20 to 25 cm in length. The eggs are deposited in groups of three to six or more, presumably in grooves rather than in individual niches. The larvae mine individually in continual contact with the cambium, away from the egg gallery and without crossing one another. Evidently the larval mine increases only slightly through
the first and second instars then expands suddenly into an irregularly oval feeding area, where the last two larval instars, pupation, and hibernation occur.

Oviposition ordinarily begins about the last week of May. The eggs hatch in about 11 days (Prebble 1933:146) and complete larval development in approximately 27 days; about 7 days are required for the pupal stage during the early summer months. Simpson found young adults in the first set of galleries completed during the season by 1 August; in the second set of galleries young adults were present by 17 September; larvae produced in the third set of galleries formed by these same parent adults passed the winter as larvae. The young adults produced in the first and second sets of galleries overwintered in those galleries and emerged the following May and early June. The overwintered larvae from the third set of galleries matured in June and emerged during July.

Notes.- Two male syntypes are in the LeConte collection; the first of these syntypes is labeled type and is here designated as the lectotype of simplex. The above treatment was based on the lectotype and on about 360 other specimens.

## 17. Dendroctonus pseudotsugae Hopkins Figs. 8I, 82, 8.3

Dendroctonus pseudotsugae Hopkins, 1905, U.S. Dept. Agric. Bur. Ent. Bull. 56:11 Neotype, female; Crants Pass, Oregon; U.S. Nat. Mus., 7.450 , present designation)
Diagnosis.- This species is distinguished from the closely related simplex LeConte by the larger size, by the more strongly protuberant, more finely punctured, subgranulate, irregular surface of the frons, by the more finely punctured pronotum, by the finer punctures of the declivital interstriae, and by the distribution.

Male.- Length 4.4-7.0 mm (average about 5.5 mm ), 2.3 times as long as wide; body color very dark brown, with reddish brown elytra.

Frons broadly convex, protruding rather strongly on lower half, inflated area arising abruptly just above smooth, elevated rim of epistomal margin; epistomal process about a fourth ( 0.24 times) as wide as distance between eyes, its arms very strongly oblique
(about 80 degrees from horizontal) and usually not elevated, horizontal portion about three-fourths its total width, flat, overlapping and apparently flush with or exceeding epistomal margin and bearing under its distal margin a dense brush of yellowish setae; surface irregular, rather finely, closely punctured and becoming granulate on lower half. Vestiture sparse, rather short, fine, inconspicuous.

Pronotum 0.71 times as long as wide, widest at base; sides weakly arcuate and
converging toward strong constriction just behind broadly, shallowly emarginate anterior margin; surface smooth and shining, punctures rather small, irregular in size, close, deep; median line narrowly impunctate posteriorly (usually); vestiture moderately abundant, fine and rather short on disc, longer, coarse laterally.

Elytra 2.5 times as long as pronotum; sides straight and subparallel on basal two-thirds, rather broadly rounded behind; basal margins arcuate and bearing a row of about 10 rather

Fis. 82. Dendroctomus psendotsugae: A, male frons; B, seminal rod; C, walleries.
large, raised, overlapping crenulations, with several smaller submarginal ones particularly on interstriae 2 and 3; striae weakly impressed, punctures rather large and moderately deep, usually decreasing slightly in size toward base; interstriae about one and onehalf times as wide as striae and armed by abundant, confused, transverse crenulations, each averaging almost half the width of an interstriae, a few two-thirds as wide on posterior half of disc. Declivity rather steep, convex, with sutural interstriae very strongly elevated and interstriae 2 weakly impressed; striae rather deeply impressed, punctures half as large as on disc; interstrial punctures rather fine, abundant and confused on 1 and 3, almost uniseriate on 2; none of punctures granulate. Vestiture rather coarse, slightly longer on declivity, longest setae equal in length to about one and one-half times the width of an interstriae.

Femiale.- Very similar to male except declivital interstriae with smaller punctures and each with a median row of very coarse, somewhat pointed tubercles, tubercles spaced by a distance slightly less than width of an interstriae.

Distribution.- British Columbia and AIberta to California and Chihuahua.

MEXICO: Chihuahua: 68 km W' San Juanito, La Magdalena.

Hosts.- Pseudotsuga menziesii, P. macrocarpa, and less commonly from Larix occidentalis and Tsuga heterophylla.

Biology.- This is a primary insect enemy of Douglas fir. Although estimate of damage inflicted by it are not available for all regions where it occurs, it may be responsible for an average annual loss approaching .5 billion board feet of timber.

The winter is passed chiefly as young adults, although some larvae and parent adults also overwinter successfully. Flight activity may begin as early as the first of April and evidently continues at least until early September. Two principal periods of flight activity occur: the first during May or June is composed of overwintered young adults; the second during July or August is composed of beetles that overwintered as larvae and of parent adults reemerging from their first set

Fig. 83. Dendroctonus pseudotsugae: A, adult; B, eggs; C, larva: D, pupa. (After Bedard 1950:3.)
of galleries. The exact timing of each principal flight period may vary from locality to locality with altitude, latitude, exposure, peculiarities of a particular season, or other local ecological factors.

Ordinarily the material selected for attack includes stumps, windfalls, broken logs, or other injured or prostrate trees larger than eight inches in diameter. However, when populations are high or when assisted by drought, healthy, vigorous standing timber may be selected. The attack on a standing tree usually begins in the upper midbole area and progresses upward and downward from that point. In prostrate material, at least when the bark is relatively thick, the beetles attack the sides and upper surfaces as well as

Fig. 83 continued, E, adults and eggs in gallery. (After Bedard 1950:5).
the lower. The attack is slow and continuous, without any sudden or concerted swarming of the beetles. Its duration is variable, evidently depending on the population density of beetles in the area, upon resistance of the host, or upon local climatic or other local ecological factors. It may be completed in a few days or it may continue for more than a year and involve two or possibly more successive generations.

The egg galleries are constructed almost entirely in the imner bark; they are in continual contact with the cambium and may very lightly score or at least stain the wood. They are straight or nearly so, and parallel the grain of the wood.

The initial attack is made by the female beetle in a crevice of the bark. Soon after beginning the attack she is joined by a male who takes over the function of removing frass from the entrance hole. Mating evidently occurs within a few hours after the cambium is reached. After the gallery has been extended several centimeters the male may pack the lower areas with the frass, thereby closing the entrance hole, or he may leave the gallery in search of another female. Most of the galleries are from about 12 to 30 cm in length, but are known to exceed 90 cm . As with other species, ventilation tunnels are placed at irregular intervals, or they may be entirely absent. The maximum number of ventilation tumnels counted in more than a hundred galleries measured during this study was four; about 80 percent of the galleries had two ventilation tunnels.

Oviposition may begin within two or three days after the attack; according to Vité and Rudinsky (1957:157) the first eggs, under controlled laboratory conditions, may appear within 36 hours after the attack begins. Eggs evidently may be found throughout the period of summer activity until about early September. According to Chamberlin (1918:20) one female may produce as many as 160 eggs in one gallery; the maximum number counted during this study was 102 in a gallery only partly complete.

Eggs are deposited in grooves about 2-4 mm deep along the sides of the gallery, near but not necessarily touching the cambium. The grooves are placed alternately on the sides, without overlapping or without more
than a few millimeters between the end of the groove on one side and the begimning of the next on the other side. The grooves vary considerably in length, ranging from less than 1 to more than 8 cm . The eggs are deposited in a single row in contact with one another and oriented with the long axis perpendicular to the egg gallery and more or less parallel to the cambium. It is presumed that the larvae emerge from the egg at the end farthest from the egg gallery. This habit of orienting the eggs is peculiar in the genus among the species observed during this study, and presumably is associated with the fact that the larvae construct independent mines, rather than working in congress as with other species that deposit masses of eggs in common grooves. The eggs are held in position by a rather thick layer or partition of coarse, fibrous frass that separates them from the egg gallery. Following the period of oviposition most of the females reemerge to construct a second set of galleries.

The period of incubation varies considerably with various factors, particularly temperature. Vité and Rudinsky (1957:161) found, under controlled conditions, that it ranged from about 6 to 28 days. Under field conditions estimates of the incubation period range from 8 to 24 days. Under controlled conditions, Vité and Rudinsky (1957:161) found that larval development required about 19 to 72 days and the pupal period
about 5 to 18 days. The larvae construct individual mines more or less perpendicular to the egg gallery and are in continual contact with the cambium area. They increase gradually in diameter and tend to fan out somewhat as they progress. Unless crowding occurs, they normally do not cross one another. Near the end of larval development a pupal chamber may be cleared in the cambium area at the end of the larval mine, or the larva may bore out into the bark for a variable distance before pupating. The young adults overwinter in the brood galleries and emerge the following spring. Larvae that develop from eggs deposited in the fall may not mature before the onset of cold weather and, therefore, pass the winter as larvae. These larvae mature early in the following summer and may emerge in July or August, or, evidently, they may overwinter in the brood galleries (Bedard 1950:9). There is one complete generation and possibly a partial second generation each year.

Notes.- Since this species was originally validated in 1905 and the type cited by Hopkins (1909aa:121) was collected in 1908, a type evidently does not exist. For this reason, the specimen considered to be the type by Hopkins (1909a:121), specified above, is here designated as the neotype of pscudotsugae Hopkins. The above treatment was based on this neotype and on about 2800 other specimens.

## Tribe PHRIXOSOMINI

Phrixosomini Wood, 1978, Ann. Soc. Ent. France 14:111 (Type-genus: Phrixosoma Blandford, 1897)

Anatomical features.- The frons is not sexually dimorphic, the eye is completely divided, the antennal funicle is 6 -segmented, the club is unmarked by sutures except that 1 is partly septate, the procoxae are contiguous, the scutellar area of the metathorax is separated from the postnotum by a definite suture, and the tibiae are armed by socketed denticles.

Biological features.-All species are monogamous and phloeophagous. The parental tunnels are biramous. Eggs are placed in niches. The larval mines follow a definite course and rarely cross one another. Symbiotic relationships with fungi have not been reported. All known species breed in tropical trees of the family Guttiferae.

Taxonomy. - The unique genus in this monobasic tribe occurs in Central and South America and in Africa. The genus appears to be ancient and apparently predates the separation of South America and Africa. Species differences are minute; some South American forms are scarcely distinguishable from some African species. They are remotely allied to the Asiatic Hyorrhynchini; both tribes apparently represent relics of ancient groups now virtually extinct.

## Genus PhrixOSOMA Blandford

[^3]Neoluylesinus Eggers, 1920, Ent. Blätt. 16:118 (Typespecies: Neohylesinus quadrioculatus Eggers, monobasic); Eggers, 1927, Rev. Zool. Afr. 15:196. Synonymy
Sphaerosinus Eggers, 1929, Tijdschr. Ent. 72:40 (Typespecies: Sphaerosinus striatus Eggers, monobasic)
Diagnosis.- The completely divided eye, the 6 -segmented antennal funicle with procurved sutures on the club, the cylindrical third tarsal segments, and the unique sexual dimorphism distinguish this genus.

Description.- Length $1.6-2.5 \mathrm{~mm}$; 2.0-2.3 times as long as wide; frons convex, not dimorphic, usually with a fine, long, median carina. Eye completely divided. Antennal scape long, funicle 6 -segmented; club slightly asymmetrical, with three procurved sutures, lateral two-thirds of 1 septate. Pronotum unarmed, punctured to obscurely granulate. Scutellum present. Elytra ascending behind on costal margin; declivity convex, gradual, short; striae impressed, punctures small to obsolete; interstriae finely granulate; vestiture short, mostly hairlike, often coarse. Anterior coxae contiguous; anterior margin of pronotum extending as ridge to coxal margin then continuing as an intercoxal ridge. Vertex sexually dimorphic in two species.

Distribution. - About 11 species from Central and South America and eight from Africa are known.

Biology. - Representatives of this monogamous genus attack the limbs and bole of trees of the family Guttiferae, where they construct tumnels in the phloem tissues. Their bi- or triramous parental galleries usually engrave the wood lightly; the short larval mines appear to wander aimlessly in the phloem.

## Key to the species of Phrixosoma

1. Slender species, 2.3 times as long as wide; pronotum closely, rather deeply punctured; striae at base of declivity almost as wide as interstriae; Costa Rica to Panama; 2.2-2.3 mm 1. rude Blandford

- Stout species, 2.0 times as long as wide; pronotum granulate, punctures obscure; striae at base of declivity about half as wide as interstriae
2(1). Interstrial granules confused throughout disc, rarely a single row toward declivital base; elytral setae much finer, often longer; frons with a fine median carina; vertex not dimorphic; Costa Rica to Panama and Colombia; Symphonia globulifera $1.8-2.5 \mathrm{~mm}$
- Interstrial granules and setae on posterior half of dise distinctly three-ranked; all elytral setae stouter, often almost scalelike; female vertex transversely
impressed and ridged impressed and ridged
3(2). Smaller; interstrial granules confused almost to middle of disc; discal interstriae usually wider, about twice as wide as striae; anterior slope of pronotum finely granulate; frons commonly devoid of median carina; female impression on vertex weak, its upper margin weakly ridged; Honduras to Panama and Venezuela; Rheedia edulis; $1.6-2.0 \mathrm{~mm}$ ally three times as wide as striae; anterior slope of pronotum obscurely if at all granulate; transverse impression on female vertex, its upper margin abruptly ridged; Honduras; in Clusia flava; $1.9-2.5 \mathrm{~mm}$ 4. clusiae Wood

## 1. Phrixosoma rude Blandford

Phrixosoma rude Blandford, 1897. Biol. Centr. Amer., Coleopt $4(6)$ : 148 (Lectotype. sex?; Volcan de Chiriquí, Panama: British Mus. Nat. Hist., present designation)
Diagnosis. - This rather unique species is distinguished from others in the genus by the more slender body form, by the very fine, hairlike pubescence, and by the more clearly, more deeply punctured pronotum.

Female.- Length $2.2-2.3 \mathrm{~mm}, 2.3$ times as long as wide; color black.

Frons broadly convex, a shallow, transverse impression just above epistomal margin; surface rather coarsely reticulate, with rather small, rounded granules, a fine, low, median carina extending from just below upper level of eyes to epistomal margin; vestiture largely confined to epistomal area.

Pronotum 0.85 times as long as wide; widest near base, sides rather strongly arcuate on basal half, weakly constricted just before rather broadly rounded anterior margin; surface shining, almost smooth, punctures moderately small, close, rather deep, oval to irregular in shape, becoming finely granulate toward base; vestiture very fine, hairlike, inconspicuous.

Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae narrowly impressed,
punctures small, moderately deep; interstriae about twice as wide as striae, armed by moderately high, isolated, rather close granules, those on 1 almost uniseriate, others confused. Declivity convex, moderately steep; interstriae narrower than on disc, more nearly convex, reticulate, granules reduced in size and number. Vestiture hairlike, three rows of setae on each interstriae, middle row slightly less than twice as long as others and slightly shorter than distance between median rows.

Distribution.- Costa Rica and Panama.
COSTA RICA: Santa Ana, San José, $8-\mathrm{XI}$ - $63,1300 \mathrm{~m}$. no. 254, Rheedia edulis, S. L. Wood. PaNAMA: Volcán de Chiriquí, G. C. Champion.

Host. - Rheedia edulis.
Biology. - One female was taken from a newly constructed entrance tunnel in the phloem of a cut limb about 7 cm in diameter.

Notes. - The above treatment was based on my Santa Ana specimen and on the two specimens of Blandford's series of three syntypes now in the British Museum. Because a type has not been selected, I here designate the first of the two specimens remaining in Blandford's series as the lectotype of the species as indicated above.

## 2. Phrixosoma obesum Blackman

Phrixosoma obesa Blackman, 194.3, Proc. U.S. Nat. Mus. 94:393 (Holotype, female; Gatún, Canal Zone. Panama; U.S. Nat. Mus., 56572)

Diagnosis. - Although not closely related, this species differs from rude Blandford by the characters summarized in the above key, by the much finer frontal granules, by the more numerous, smaller elytral granules, by the more abundant elytral vestiture, and by other characters.

Female.- Length $1.8-2.5 \mathrm{~mm}, 1.9$ times as long as wide; color black.

Frons as in rude except frontal granules much smaller and more widely spaced.

Pronotum 0.80 times as long as wide; widest at base, sides weakly arcuate, strongly converging to prominent constriction just before broadly rounded anterior margin; surface rather finely, shallowly punctured near center, punctures largely replaced in basal and lateral areas by small, irregularly formed, rounded granules or rugae, with rather coarse reticulation interspersed in depressions; vestiture fine, rather short, hairlike.

Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal half, rather narrowly rounded behind; striae strongly impressed, punctures rather fine; interstriae three or more times as wide as striae, surface strongly reticulate, rather densely armed by isolated, confused granules. Declivity convex, moderately steep; interstriae less than twice as wide as striae, tubercles less definite, uniseriate. Vestiture reddish yellow, consisting of rather abundant fine, short, interstrial hair, and a row of longer bristles on each interstriae; bristles fine toward base, course on declivity, almost twice as long as ground vestiture, about two-thirds as long as distance between rows.

Male.- Distinguished from female only by differences in posterior abdominal terga.

Distribution.- Costa Rica and Panama to Colombia and (?)Brazil.

COSTA RICA: Moravia, Cartago, 11-III-64, 500 m , no. 470 . Symphonia globulifera, S. L. Wood; Río Damitas, Dota Mountains, San José, 18 -II-64, 500 m , No. 434 , Symphonia globulifera, S. L. Wood. PANAMA: Gatún, Canal Zone, 7 -1V-11, Schwarz. OTHER COUNTRIES: Colombia, (?) Brazil (one doubtful specimen in the Canadian Nat. Coll.).

Host.-Symphonia globulifera, Rheedia madruño (Colombia).

Biology.- Felled trees about $25-35 \mathrm{~cm}$ in diameter were attacked in large numbers. The larvae almost completely consumed the
phloem tissues. Apparently the adult galleries were biramous and transverse; they scarcely engraved the wood.

Notes.- Examples from Moravia used for the above treatment were compared to the type. For this study 36 specimens were examined.

## 3. Phrixosoma minor Wood Fig. 98

Phirixosoma minor Wood, 1956, Canadian Ent. 88:248 (Holotype, male; La Ceiba, Honduras; Wood Coll.)
Diagnosis.- This species is distinguished from clusiae Wood by characters summarized in the above key.

Female.- Length $1.6-2.0 \mathrm{~mm}, 2.0$ times as long as wide; color black.

Frons below upper level of eyes as in obesum except carina shorter, often absent, vestiture above more conspicuous; lateral area of vertex just above and behind eye with margin of facial sculpture strongly sinuate, very weakly impressed; impression continuing along pubescent margin of vertex to a slight sinuation on median line, dorsolateral margin of pronotum with a matching, less well developed sinuation.

Pronotum 0.77 times as long as wide; widest at base, weakly arcuate and feebly converging on basal third, then strongly, arcuately converging to moderate constriction just before broadly rounded anterior margin; surface finely, very closely, shallowly punctured, very finely, obscurely granulate behind, obscurely reticulate in most areas, minutely asperate in anterior areas; vestiture of fine, semirecumbent hair and rather coarse, erect hair.

Elytra 1.3 times as long as wide, 1.8 times as long as pronotum; outline as in obesum; striae impressed, punctures small, moderately deep; interstriae about twice as wide as striae, surface reticulate, armed by closely set, isolated granules, these confused on basal third, in three distinct ranks to declivity, two marginal ranks gradually reduced on declivity and obsolete before middle. Declivity convex, moderately steep; interstriae not wider than striae, more nearly convex, each with a median row of obscure granules. Vestiture of coarse, short setae, largely in three rows on each interstriae, median bristle a third longer
than lateral setae and about two-thirds as long as distance between rows of bristles.

Male.-Similar to female except vertex and anterior margin of pronotum not modified by impression or sinuation.

Distribution. - Honduras to Panama, Colombia, and Venezuela.

HONDURAS: La Ceiba, Atlantida, 20, 26, 29-V, 1, 10V1, 26-VIll-49, at light, E. C. Becker. COSTA RICA: Santa Ana, San José, 30-VIII, 8-IX-63, 1300 m. Nos. 157 , 254, Rheedia edulis, S. L. Wood; Playón, Puntarenas, 25 m, No. 453, Symphonia globulifera, S. L. Wood. PANAMA: Barro Colorado Island, Canal Zone, 70 m , No. 234, Symphonia globulifera, S. L. Wood. OTHER COUNTRIES: Colombia, Brazil, Venezuela.
Hosts.-Rheedia edulis and Symphonia globulifera.

Biology. - The bole and branches down to about 3 cm in diameter are attacked. The egg galleries are primarily biramous and transverse, although diagonal or even partly longitudinal systems were not uncommon and several were triramous. The larval mines were rather short and wandered indiscriminately.

Notes. - The holotype, allotype, six paratypes, and 216 other specimens were examined. Those from Costa Rica and Panama tended to have the impression on the female vertex more strongly developed, but the difference was slight.

## 4. Phrixosoma clusiae Wood

Phrixosoma clusiae Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2): 1 (Holotype, female; Zamorano, Morazán, Honduras: Wood Coll.)
Diagnosis.- This species is distinguished from minor Wood by the larger size, by the much more strongly impressed female vertex, and by other characters mentioned in the above key.

Female.- Length 1.9-2.5 mm, 1.9 times as long as wide; color black.

Frons broadly convex with epistomal margin to upper level of eyes; rather strongly,
transversely, arcuately impressed from just above upper level of eyes to vertex, upper margin of this groove abruptly angled; lateral angles of groove produced laterally, causing a pronounced sinuation in line where pubescent and nonpubescent areas meet; vestiture hairlike, short, rather abundant, extending to vertex.

Pronotum 0.80 times as long as wide; widest at base, sides uniformly, convergently arcuate to weak constriction just before rather narrowly rounded anterior margin; anterior third very minutely asperate, asperities on margin somewhat larger; surface rather closely marked by low, subtuberculate, short, irregular rugae (remnants of interspaces between obsolete punctures), depressed areas reticulate; vestiture consisting of very fine, short hair.

Elytra 1.2 times as long as wide; 1.7 times as long as pronotum; outline as in obesum; striae narrowly impressed, punctures small, distinct; interstriae almost three times as wide as striae, reticulate, granules rather large rounded, three-ranked almost to base except on 2, marginal rows of granules becoming smaller by middle of disc and obsolete by upper fourth of declivity. Declivity and vestiture as in minor.

Male.-Similar to female except frontal carina absent, vertex and anterior margin of pronotum not modified, and asperities on anterior third of pronotum almost obsolete.

Distribution.- Honduras.
HONDURAS: Zamorano, Morazán, 18-V1-64, 700 m , No. 561, Clusia flaca, S. L. Wood.

Host.- Clusia flava.
Brology.- Essentially as described above for minor.

Notes. - The above treatment was modified from the original description and was based on the type series of 12 specimens.

# Tribe BOTHROSTERNINI 

Bothrosternı Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6):120 (Type-genus: Bothrosternus Eichhoff, 1868)

Anatomical features.- The frons is usually sexually dimorphic, the eye is entire, the antennal funicle is 6 -segmented, the club symmetrical, moderately flattened, the sutures are indicated, the procoxae are moderately separated, the pronotum is unarmed, the protibia bears a bifid process on the outer apical angle that exceeds the inner apical angle, crenulations on the elytral bases are poorly developed, and the metatergum is fused to its postnotum and at least the median half of the suture is obliterated.

Biological features.- All species are thought to be monogamous; however, there are indications that some type of parthenogenesis occurs in Bothrosternus. Most species are pith borers in twigs and small branches, except Pagiocerus breeds in large seeds and Bothrosternus apparently is mycetophagous in pith tunnels. Cnesinus annectens Wood forms a connecting link between the biramous tunnels in the cambium and the pith feeding habits (see the biology of that species). The eggs are usually placed loosely or packed indiscriminantly in frass in part of the parental tunnel; the larvae usually feed communally as they extend the parental gallery.

Taxonomy.- This tribe is restricted to the American tropics, although two species extend their ranges into the southeastern United States. Their closest relatives appear to be the Diamerini of Africa and the IndoAustralian area. Although this tribe is unique in the American fauna, the genera within the tribe differ from one another only slightly and may be recognized with difficulty in some instances.

## Genus CnesinuS LeConte

Cnesinus LeConte, 1868, Trans. Amer. Ent. Soc. 2:171 (Type-Species: Cnesinus stigicollis LeConte, monobasic)

Nemophilus Chapuis, 1869, Synopis des Scolytides, p. 27
(Type-species: Nemophilus strigillatus Chapuis
$=$ Cnesinus strigicollis LeConte, subsequent designation by Hopkins, 1914:125); LeConte, 1876, Proc. Amer. Philos. Soc. 15:378. Synonymy
Diagnosis.- Within the Bothrosternini this genus is distinguished by the rounded lateral margins of the pronotum and by the straight, transverse sutures of the antennal club.

Description.- Length 1.6-3.5 mm, 2.4-2.8 times as long as wide; male frons flattened to moderately excavated on lower half and usually ornamented, sometimes elaborately, by setae, female frons shallowly impressed to strongly convex, the sculpture often simple, but in many species variously armed by tubercles, carinae, and setae. Eye sinuate to shallowly emarginate on anterior margin, often oval and widely separated, at times very elongate and subcontiguous. Antennal funicle 6 -segmented; club slender, symmetrical, about two to three times as long as wide, about equally divided by three straight, transverse sutures, suture 3 obsolete in some species. Pronotum varying from smooth, with fine punctures, to coarsely, longitudinally strigose; usually unarmed. Scutellum small, round. Crenulations on elytral bases small, close, abundant, obscurely defined laterally in most species, in most primitive species elytral bases transversely carinate with punctures positioned just behind points where crenulations should be located; striae varying from unimpressed with normal punctures to narrowly, deeply impressed with confluent or even obsolete punctures; interstriae usually weakly convex, subcarinate in two species. Declivity convex to shallowly impressed, unarmed except for small tubercles in a few species. Vestiture varying from almost total absence to very abundant; usually hairlike, rarely with scales.

Distribution.- Southeastern United States and central Mexico to Argentina. Approximately 70 species are known; 38 are from Mexico and Central America, one species occurs in the United States.

Biology.- The adult female bores in small twigs, branches, or woody vines usually $0.5-2.0 \mathrm{~cm}$ in diameter, where she is joined by a male, then constructs a simple, unbranched, axial tunnel that may extend in either or both directions from the entrance tunnel. Eggs are scattered in the frass in the tunnel, usually near the ends. The larvae widen and extend the parental gallery and do not
construct individual mines. The young adults normally emerge through the parental entrance hole. One species (annectens Wood) departs radically from the usual habits and provides an interesting and perhaps significant behavioral connection to other bark beetles. A mated female evidently can construct a second or perhaps even a third parental gallery without the aid of a male. In some local populations of certain species males are uncommon or entirely absent. The disproportionate number of females suggests partial parthenogenesis, although this has not been demonstrated.

## Key to the Species of Cnesinus <br> (Modified from Wood 1968)

1. Elytral vestiture largely confined to declivity (except degener), hairlike; pronotal punctures usually elongate but ordinarily not strongly strigose; female frons without a transverse carina, an epistomal elevation may occur in either sex; striae usually less strongly impressed, punctures larger and usually impressed individually (except retifer); interstrial punctures tending to be uniseriate (several exceptions)

- Elytral vestiture abundant, normally extending to base, essentially scalelike, less commonly hairlike; pronotum longitudinally strigose (except frontalis); frons of one sex or both commonly with a carina or other prominent elevation; striae commonly abruptly, deeply impressed, punctures usually partly confluent or even obsolete; interstrial punctures usually more abundant, confused
2(1). Frons devoid of an epistomal elevation in both sexes, male without conspicuous epistomal vestiture; entire frontal area dull, reticulate, lower area at most flattened, upper area rather strongly, broadly convex; small species, $1.6-2.2 \mathrm{~mm}$
- Frons with a conspicuous epistomal callus or other elevation, male, sometimes also female, with at least one transverse row of stout setae on upper margin or upper slope of callus; frontal area usually partly or entirely shining, moderately to strongly impressed on at least part of lower half; size variable, 1.5-3.5 mm
3(2). Interstriae on posterior half of disc and on declivity narrowly costate, discal surface dull, minutely rugose-reticulate over striae and interstriae; pronotal disc with long, fine, rather abundant hair; Costa Rica; 2.5 mm

## 1. bicostatus Schedl

- Interstriae flat to moderately convex, except bicostate from base in costulatus and porcatus
4(3). Surface of pronotum and elytra reticulate, dull; strial punctures confluent, almost entirely obsolete; declivital bristles stout, spaced within a row by distances equal to two-thirds length of a bristle, between rows by length of a bristle; Panama; 1.8-2.0 mm bristles somewhat more slender, spaced within rows and between rows by length of a bristle

5(4). Eyes separated by 2.2 times width of an eye; female frons between upper part of eyes transversely convex and ornamented by abundant, fine, moderately long, yellowish hair; convexity of male frons more pronounced and extensive, not more than lower third flattened; declivital striae 2 and 3 equally impressed; interstriae 2 devoid of granules, 3 sometimes with a few minute granules; Honduras to Colombia; 1.8-2.1 mm
3. gracilis Blandford

- Eyes separated by 1.5 times width of an eye; female frons transversely flat, vestiture sparse, inconspicuous; lower half of male frons flattened; declivital striae 1 much more strongly impressed than 2 , interstriae 2 and 3 each armed by a row of rounded granules; Guatemala to Panama; 1.5-1.8 mm

4. pullus Blandford
$6(2)$. Male epistomal callus unarmed by tubercles, female callus bearing on dorsal slope a tuft of uniformly short, stout, decorative bristles (except only one row in electus in which eyes separated by much less than width of an eye); smaller species, $1.6-2.9 \mathrm{~mm}$

- Female epistomal callus armed by a pair of pointed tubercles or by a large, unpaired elevation, male callus ornamented by not more than one uniseriate, transverse row of only slightly modified decorative bristles; eyes always separated by a distance at least as great as width of an eye; larger species, 2.5-3.9 mm
7(6). Eyes separated above by less than 1.0 times width of an eye ....................................... 8
- Eyes separated by more than 2.0 times width of an eye

8(7). Female epistomal callus poorly developed, its lower slope descending gradually, upper slope ornamented by only one transverse row of ornamental bristles; declivital interstriae 1 to 3 feebly if at all convex; declivital interstrial vestiture consisting of rows of erect bristles and moderately sparse, fine, supplemental hair; Costa Rica; 2.3-2.6 mm

5. electus Wood

- Epistomal callus of male abruptly precipitous below, its upper slope ornamented by numerous bristles not confined to a single row; declivital interstriae rather narrowly convex; declivital vestiture consisting entirely of rows of erect, interstrial bristles; smaller species
9(8). Ornamental bristles on female epistomal callus longer, about equal in length, thickness, and color to those on other frontal areas above; punctures on anterolateral area of pronotum elongate, rarely confluent; punctures of pronotum and elytra very slightly larger; Costa Rica to Panama; $1.6-1.9 \mathrm{~mm}$

6. intermedius Schedl

- Ornamental bristles on female epistomal callus reddish in color, about half as long as more slender yellowish setae on other frontal areas; punctures on anterolateral area of pronotum elongate and many confluent, appearing more nearly substrigose; punctures of pronotum and elytra very slightly smaller, Veracruz to Colombia; 1.7-1.9 mm

7. blackmani Schedl
$10(7)$. Body stout, less than 2.1 times as long as wide; Puebla to Panama; 2.3-3.0 mm 8. punctatus Blandford

- Body more slender, at least 2.4 times as long as wide; smaller species, 2.0-2.5 mm
11(10). Pronotum rather deeply, coarsely punctured, punctures mostly very elongate (about three or more times as long as wide), substrigose; interstriae more narrowly convex, only slightly wider than striae; Panama; $2.0-2.5 \mathrm{~mm}$
- Pronotum with rather fine, shallow punctures, punctures oval, rarely as much as twice as long as wide (one specimen very shallowly, minutely substrigose); interstriae less strongly convex, almost twice as wide as striae
12(11). Lower margin of female epistomal callus sharply, rather precipitously defined along an almost straight, transverse line; body 2.6 times as long as wide, pronotum with minute points between punctures (at 40X magnification); striae less strongly impressed; Jalisco; 2.1-2.5 mm

10. electinus Wood

- Lower margin of female epistomal callus not sharply defined, with a fine median tubercle (absent in a few specimens) on lower margin; body 2.4 times as long as wide; pronotum with minute points scarcely visible at 80 X ; striae more strongly impressed; Puebla; 2.0-2.4 mm 11. myelitis Wood

13(6). Female epistomal callus armed by a pair of pointed tubercles; declivital interstriae feebly if at all convex, armed by rows of fine setiferous granules

- Female epistomal area armed by an unpaired median elevation; declivital interstriae narrowly convex, not high, entirely unarmed ..... 20
14(13). Frons concavely impressed to slightly above upper level of eyes, female epis- tomal tubercles very large; pronotal punctures obsolete, surface strongly, lon- gitudinally strigose; discal interstriae each armed by median row of rounded granules; Michoacán to Morelia; $3.3-3.8 \mathrm{~mm}$

12. bicornus Wood

- Frontal impression ending well below upper level of eyes, female epistomal tubercles much smaller; pronotum substrigose, elongate punctures distinct; discal interstriae unarmed by granules (except degener); smaller species
15(14). Elytral vestiture extending to disc, ground vestiture rather abundant, stout; dis- cal interstriae with fine granules; body stout, $2.4-2.5$ (brighti 2.7 ) times as long as wide ..... 16
- Elytral vestiture usually absent on disc, ground vestiture (when present) fine, hairlike; body more slender, more than 2.7 (coracinus 2.5) times as long as wide; female frons usually more strongly convex between eyes; mostly larger, $2.1-3.4 \mathrm{~mm}$ ..... 18

16(15). Discal interstriae almost flat, without evident granules; body slender, 2.7 times as long as wide; discal strial punctures small, separately impressed; elytral vestiture abundant, rather coarse, length of each seta about equal to width of interstriae; Chiapas; 2.2-2.6 mm

17(16). Smaller; interstrial bristles about as long as width of one interstriae; declivity with strial punctures rather coarse and interstriae 2 and 3 with distinct granules; Oaxaca to Veracruz; $2.0-2.3 \mathrm{~mm} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ~ 13 . ~ d e g e n e r ~ W o o d ~$

- Larger; interstrial bristles at least twice as long as width of one interstriae; declivity with strial punctures rather fine, interstriae 1-3 without evident granules; Guatemala; 2.8 mm ................................................... 14. paleatus Blandford
18(15). Pronotum almost smooth, punctures oval to elongate, rarely confluent; frontal pubescence long, evidently more abundant; Puebla and Veracruz to Panama and Venezuela; $2.4-2.8 \mathrm{~mm}$ (see also 17. theocallus)

16. elegans Blandford

- Pronotum moderately strigose, most punctures longitudinally confluent; frontal pubescence much shorter, less abundant, rather inconspicuous
19(18). Larger, more slender; declivital setae more slender, at least twice as long as distance between rows; declivital interstrial granules almost obsolete; Chiapas
to Guatemala; $3.0-3.4 \mathrm{~mm} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ~ 18 . ~ e l e g a n t i s ~$

Smaller, stouter; declivital bristles rather stout, in definite rows, each as long as
distance between rows; declivital interstrial granules conspicuous on all
interstriae; Chiapas; 2.1-2.3 mm ................................................19. coracinus Wood
20(13). Epistoma armed by a rather small, median tubercle; pronotal punctures oval, not extended by longitudinal strigose lines; punctures obsolete on declivital striae 1-3; Morelos(?); 2.3 mm
20. garrulus Schedl

- Median epistomal elevation large, flattened on its summit, its sides precipitous; pronotal punctures elongate, usually extended by longitudinally strigose lines; strial punctures evident on declivity
21(20). Epistoma armed by a large, median, pentagonal elevation, its sides precipitous, flattened on its summit, its two dorsal sides pubescent; declivital interstriae 2 convex, its punctures displaced to its mesal base, its convexity impunctate; Costa Rica; 2.8-3.5 mm

23. gibbosus Wood

- Epistoma armed by a large, median, subtriangular elevation, its sides precipitous, its summit flattened, its lower margin arcuate, its upper margins straight and pubescent; declivital interstriae 2 convex and punctured along its summit
$22(21)$. Larger; pronotal punctures oval, feebly if at all strigose, almost never confluent; eyes more narrowly spaced; central area of frons smooth, brightly shining; "Mexico"; 3.0 mm

21. quaesitus Schedl

- Smaller; pronotal punctures much more strongly strigose, about a third of them longitudinally confluent; eyes more widely spaced; central area of frons minutely, transversely strigose; Costa Rica; 2.4-2.8 mm

22. gibbulus Wood

23(1). Female frons not armed by a transverse carina; male frons rather broadly impressed at least on lower half, extending in some species to above upper level of eyes; male epistoma variable, ornamental bristles usually more extensive (entirely absent in annectens)

- Female frons armed by a transverse carina well above epistomal area and below upper level of eyes; males of several species lack a frontal impression, impression never extending more than half distance from epistomal margin to upper level of eyes; male epistoma ornamented by only one uniseriate, transverse row of bristles (a double row in one species)
24(23). Female frons flattened to well above upper level of eyes, lower two-thirds of median three-fourths occupied by a subcircular, very minutely, densely pilose area; male frons broadly, subconcavely impressed on lower two-thirds of area below upper level of eyes; vestiture on pronotum and on elytral dise fine,

- Female frons strongly impressed below, impression ending below upper level of eyes; epistomal callus developed, specialized bristles much less extensive, either entirely absent or much longer; epistomal callus evident in male and usually ornamented by a transverse row of setae on its upper margin; setae on elytral dise at least partly stout, almost scalelike; smaller
25(24). Anterolateral angles of pronotum armed by a row of small, basally contiguous asperities; ground vestiture on elytral disc hairlike, median row of stout bristles on each interstriae at least as long as distance between rows and spaced within rows by similar distances; Costa Rica; 2.0-2.3 mm
- Anterolateral angles of pronotum unarmed; elytral ground vestiture on dise stout, more than half as long as erect bristles, bristles more closely spaced within row, not more than two-thirds as long as distance between rows

26(25). Female frontal impression extending two-thirds of distance to upper level of eyes, convex above; epistomal callus narrowly carinate, occupying median two-thirds, its upper slope and lower third (or more) of impressed area bearing long, reddish, ornamental bristles; female epistomal callus evident, one transverse row of simple setae present; pronotum more coarsely strigose; strial punctures largely confluent; declivital striae rather strongly impressed; Veracruz; 2.2-2.5 mm
26. atavus Wood

- Female frontal impression extending to about upper level of eyes; epistomal callus reduced, not occupying more than median half in either sex, not ornamented by setae, except for long, fine hair on lateral and upper margins in impression of male; pronotum obscurely strigose, rather closely granulose; strial punctures mostly distinct; declivital striae only moderately impressed; Honduras; $1.9-2.5 \mathrm{~mm}$

27. annectens Wood

27(23). Elytral striae on disc very strongly impressed, sutural interstriae carinate, others essentially bicarinate, with median area subsulcate and uniseriately punctured between elevated margins, vestiture hairlike; female carina almost straight, extending from eye to eye at level of ocular emargination

- Discal interstriae flat or convex, never carinate, punctures confused, vestiture usually abundant, somewhat scalelike; female carina crescent-shaped, its arms extending slightly dorsolaterad, usually shorter and usually located somewhat lower on frons 29

28(27). Smaller, $2.0-2.3 \mathrm{~mm}$; female frons above carina shining, usually with a few minute impressed points; ground vestiture on elytral declivity less abundant, major setae usually finer and longer; pronotal rugae usually slightly coarser; Costa Rica to Panama and Colombia
28. costulatus Blandford

- Larger, $2.8-3.1 \mathrm{~mm}$ : female frons above carina reticulate, dull; declivital ground vestiture more abundant, major setae usually coarser and shorter; pronotal rugae usually finer; Guatemala to Venezuela

29. porcatus Blandford

29(27). Elytral apices extended posteriorly and broadly emarginate at suture; declivital interstriae 1,5 , and 9 elevated; discal ground vestiture on elytra consisting of broad scales, each scale almost as wide as long; Costa Rica to Panama and Venezuela; 1.7-2.1 mm
30. squamosus Wood

- Elytra rather broadly rounded behind, discal vestiture on elytra more slender, each seta at least four times as long as wide; declivital interstriae not conspicuously elevated
30(29). Female transverse frontal carina occupying more than two-thirds width of
frontal area (at level of antennal bases), its lower margin (in median area) at
level of antennal insertion; punctures of pronotum rather large, not oriented in
longitudinal rows, rarely confluent; elytral vestiture consisting of rows of long
slender bristles to base, very short, sparse, ground vestiture confined to
declivity; Costa Rica; $2.0-2.3 \mathrm{~mm} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ~ 31 . ~ f r o n t a l i s ~ W o o d ~$
- Female carina much shorter, usually located well above level of antennal bases; punctures of pronotum mostly oriented in longitudinal rows of four or more or entirely obliterated by longitudinal confluence; ground vestiture on elytra more widely distributed and usually proportionately longer
$31(30)$. Eyes more widely separated, separated by at least 1.8 times width of an eye .......... 32
- Eyes more narrowly separated, separated by less than 1.6 times width of an eye (if doubtful female frontal carina short)37
32(31). Female transverse frontal carina narrow, width of frons at level of antennal insertion more than 4.0 times transverse length of carina ..... 33
- Female carina broad, width of frons at level of antennal insertion less than 2.9 times transverse length of carina 35

33(32). Female frons rather strongly, transversely impressed immediately above carina, rather strongly convex at and above upper level of eyes; female carina very strongly elevated, almost as high as transverse length of its apex; most of setae in declivital ground vestiture amost as wide as long, longer, erect setae almost twice as long as ground vestiture; Costa Rica and Panama to Venezuela; $1.8-1.9 \mathrm{~mm}$
32. denotatus Wood

- Female frons more nearly flattened, carina much less strongly elevated; setae in declivital ground vestiture slender, usually four or more times as long as wide and two-thirds or more times as long as major setae

34(33). Female frons weakly convex above carina; female carina conspicuously elevated; eyes separated by 1.8 times width of an eve; declivital striae feebly impressed; Veracruz; 2.5-3.3 mm (see also 34. prominulus Wood, Jalisco) $\qquad$
33. minax Schedl

- Female frons flattened from just below carina to above upper level of eyes; female frontal carina low, feebly elevated; eyes separated by 2.2 times width of an eye; declivital striae rather strongly impressed; Honduras; $2.0-2.3 \mathrm{~mm}$

35. adustus Schedl

35(32). Discal vestiture on elytra fine, major erect setae usually pointed, not expanded distally; female frontal carina shorter, distance between eyes 2.4 times length of carina; interstrial granules on declivity absent; Michoacán; 2.5-3.1 mm
38. carinatus Wood

- Discal vestiture on elytra rather coarse, major, erect setae blunt, each seta wider distally; female frontal carina longer, distance between eyes only 1.8 times length of carina; interstrial granules on declivity moderately large
36(35). Larger, stouter; erect interstrial bristles much less abundant, each conspicuously shorter than distance between bristles within a row; female frons below carina less strongly impressed, impunctate area above carina larger; Sinaloa; 3.1 mm

36. pilatus Wood

- Smaller, more slender; erect interstrial bristles more abundant, longer, conspicuously longer than distance between bristles within a row; female frons more strongly impressed below carina, impunctate area above carina smaller; Michigan and New York to Texas and Florida, Chiapas; 2.2-2.7 mm

37. strigicollis LeConte

37(31). Striae on elytral declivity more strongly impressed, interstriae rather narrowly convex (except lower half of 2 in some specimens) and each armed by a row of small rounded granules; distance between eyes exceedingly variable, 0.6-1.6 times width of an eye, but commonly constant within a series, possibly a polytypic species; Colima and Tamaulipas to Panama; 1.8-2.6 mm
39. setulosus Blandford

- Declivital striae feebly if at all impressed, interstriae not elevated or armed by granules (occasional males with feeble granules on upper half); eyes separated by 1.0 or more times width of an eye; larger species 38
38(37). Frontal carina in female short, low, distance between eyes more than five times greater than length of carina; discal interstriae devoid of granules; longest bristles on elytral declivity usually much less than twice as long as ground vestiture; Costa Rica; $3.0-3.5 \mathrm{~mm}$

Frontal carina in female longer, distance between eyes less than 3.5 times as long as carina; discal interstriae armed by sparse rows of very fine, rounded granules; longest declivital bristles usually much more than twice as long as ground scales; Honduras to Colombia; 2.6-3.3 mm $\qquad$ 41. adusticus Wood

## 1. Cnesinus bicostatus Schedl

Cnesinus bicostatus Schedl, 1936, Arch. Inst. Biol. Veg. Río de Janeiro 3:106 (Holotype, male; Turrialba, Costa Rica; Schedl Coll.)
Diagnosis.- This species would be placed in Sternobothrus except that the lateral margins of the pronotum are not acutely costate. The costate elytral interstriae resemble those of S. sculpturatus (Blandford), not Cnesinus porcatus Blandford or costulatus Blandford. It is distinguished from all other Central American Cnesinus by the median interstrial costae that begin on the disc one-fourth of the elytral length from the base and continue to near the apex of the declivity, their greatest height being on the declivity.

Male.-Length $2.5 \mathrm{~mm}, 2.2$ times as long as wide; color almost black.

Frons broadly convex, a rather abrupt, transverse impression just above level of antennal insertion; surface rugose-reticulate except rather obscurely reticulate on median third on upper half; vestiture restricted to sides and lower third, of short, moderately stout hair; vestiture similar to male Sternobothrus bicaudatus (Blandford)

Pronotum 0.85 times as long as wide; widest just behind middle, sides on basal half weakly arcuate, diverging slightly, more strongly arcuate on anterior half, very broadly rounded in front; surface strongly, closely, longitudinally aciculate, ridges very narrow, acutely rounded, shining, half as wide as grooves, grooves apparently subreticulate, mostly longitudinally confluent. Vestiture of very fine, long hair, rather abundant and unusually long in discal area.

Elytra 1.5 times as long as wide, 2.0 times as long as pronotum; sides feebly arcuate on basal two-thirds, rather narrowly rounded behind; striae shallowly impressed as continuous grooves, punctures not clearly evident; interstriae almost flat on basal fourth of dise, gradually becoming narrowly costate toward declivity; discal surface dull, minutely rugose-reticulate over striae and interstriae, except costae smooth, shining. Declivity
moderately steep, convex, very slightly inflated near apex; strial grooves deeper and slightly wider than on dise, punctures clearly impressed; interstriae as wide as striae and narrowly costate on upper two-thirds, about as high as wide, becoming subserrate below, 1-3 continuing to near apex. Vestiture largely confined to declivital interstriae, short, fine and longer coarser hair arising from margins of costae.

Distribution.- Costa Rica.
COSTA RICA: Turrialba, 800 m, SLC, Sched!.
Notes.- The above treatment was based on the holotype.

## 2. Cnesinus retifer Wood

Fig. 85
Cnesinus retifer Wood, 1967, Great Basin Nat. 27:85 (Holotype, male; Ft. Clayton, Canal Zone, Panama; Wood Coll.).
Diagnosis.- This species is distinguished from gracilis Blandford by the very strongly convex frons, by the completely reticulate pronotum and elytra, and by the confluent punctures of the declivital striae.

Male.- Length $1.9-2.0 \mathrm{~mm}, 2.9$ times as long as wide; color very dark brown.

Frons strongly convex almost to epistoma; surface coarsely reticulate, with minute, rather sparse granules; vestiture short, sparse, inconspicuous.

Pronotum 1.1 times as long as wide; sides straight, diverging slightly from base to widest point two-fifths length from anterior margin, broadly rounded in front; a conspicuous, smooth, shining callus extending from anterolateral angles more than half distance toward median line just behind anterior margin; remainder of surface reticulate, dull, with rather large, shallow, oval punctures in posterior area, and small, deep, elongate punctures anteriorly; anterior punctures often confluent, posterior punctures usually separate; glabrous.

Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; sides straight and subparallel to base of declivity, rather narrowly
rounded behind; bases marginally and submarginally rugose, feebly elevated, crenulations obscure if not entirely absent; striae moderately impressed, punctures confluent; interstriae about one and one-half times as wide as striae, except 1 narrower, punctures very fine, deep, uniseriate except at base of 3 . Declivity convex, rather steep; interstriae narrower than striae, convex, 1 very slightly more strongly elevated. Vestiture confined to declivity, consisting of interstrial rows of flattened bristles; each bristle as long as distance between rows of bristles.

Distribution.- Panama.
PANAMA: Ft. Clayton, Canal Zone, 22-XII-63, 30 min, S. L. Wood.

Host.-A woody vine, possibly Seriania sp.

Biology.- Collected from new, incomplete, axial tunnels in a recently cut vine about 5 mm in diameter.

Notes.- The above treatment was based on the six males in the type series.

## 3. Cnesinus gracilis Blandford Fig. 85

Cnesinus gracilis Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6):141 (Holotype, female; Volcan de Chiriqui, Chiriqui, Panama; British Mus. Nat. Hist.)
Cresinus substrigatus Blackman, 1943, Proc. U.S. Nat. Mus. 94:376 (Holotype, female; Santander, Colombia; U.S. Nat. Mus., 56554); Wood. 1971, Great Basin Nat. 31:144. Synonymy
Diagnosis.- This species is distinguished from the allied pullus as indicated in the above key. It is much more closely related to nitidus Eggers (from Bolivia and Peru), from which males differ by the less strongly convex frons, by the almost total confluence of punctures on discal striae 1, by the less strongly, more narrowly impressed elytral declivity, by the more narrowly convex declivital interstriae 3; and by the slightly smaller size ( $2.4-2.6 \mathrm{~mm}$ in nitidus; only males examined).

Female.- Length $1.8-2.1 \mathrm{~mm}, 2.7$ times as long as wide; color black.

Frons transversely impressed on lower third, rather strongly, broadly convex on upper third of area below upper level of eyes; epistomal margin shining, slightly elevated, remaining surface reticulate-granulate with a few larger granules on upper third; surface
from epistoma to just below upper level of eyes bearing rather abundant, reddish, subplumose hair of uniform length, its length about equal to half width of eye, these setae most conspicuous in central area.

Pronotum 1.1 times as long as wide; sides straight and subparallel on basal two-thirds, rather broadly rounded in front; surface obscurely reticulate-granulate on posterior third becoming coarsely rugose-reticulate by anterior fourth, punctures isolated, longitudinally elongate, about twice as wide on basal fourth as on anterior fourth, sepated by half width of a puncture on posterior area, by more than width of a puncture on anterior third. Glabrous.

Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel to declivital base, somewhat narrowly rounded behind; declivity confined to posterior fourth; basal crenulations small, poorly defined; striae 1 moderately, others rather weakly impressed, punctures on 1 almost totally confluent, their positions obscurely indicated, small but rather clearly indicated on other striae; interstriae about twice as wide as striae, almost smooth, punctures slightly more than half as large as those of striae, essentially uniseriate except more staggered on 2. Declivity rather steep, convex, except almost flat on lower two-thirds between third interstriae; strial punctures deeper than on disc; interstriae 1,3 , and lateral half of 2 convex, weakly elevated, 2 and 3 armed by rather widely spaced, rounded granules, 1 with minute granules indicated on upper half. Vestiture confined to declivity, consisting of rows of erect, flattened bristles, spaced in rows and between rows by about two-thrids length of a bristle.

Male.-Similar to female except frontal convexity a little more extensive, frontal vestiture almost entirely absent; granules on declivital interstriae 1 and 2 almost entirely obsolete, reduced on 3 .

Distribution.- Honduras to Colombia.
HONDURAS: La Ceiba, Atlantida, 28-VI-49, at light, E. C. Becker. COSTA RICA: Finca Gromaco, Puntarenas, 14 -VII- $63,500 \mathrm{~m}$, No. 64 woody vine, No. 76 from broken twig, S. L. Wood; San Ignacio de Acosta, San José, 5-VII-63, 1500 m , No. 28 broken twig of cultivated tree, S. L. Wood. PANAMA: Ft. Clayton, Canal Zone, 22-XII-63, 30 m , No. 319, from Serjania, No. 329, from a cut vine. COLOMBIA: Santander, $700-\mathrm{I} 300 \mathrm{~m}$, Coffea arabica, R. P. Roba.

Hosts.- Coffea arabica, Seriania sp., etc.
Biology.- Specimens were taken from tunnels in the pith of stems smaller than 1 cm in diameter. The larvae are pith feeders.

Notes.- The holotypes of gracilis and substrigatus and 38 other specimens were examined. The above description was based on my female homotypes of gracilis and of substriatus. The female from Honduras has the frontal impression very slightly deeper and more extensive than those from Costa Rica to Colombia.

## 4. Cnesinus pullus Blandford Fig. 85

Cnesinus pullus Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6):141 (Lectotype, female; Cerro Zunil, Guatemala: British Mus. Nat. Hist., present designation)
Diagnosis.- This species is allied to gracilis Blandford as indicated in the above key. It also has the anterior margins of the elytra acutely costiform, not crenulate in the usual fashion.
Female.- Length $1.5-1.8 \mathrm{~mm}, 2.5$ times as long as wide; color black, declivity and occasionally elytra a lighter brown.

Frons flattened and transversely impressed on lower half of area below upper level of eyes, very weakly, longitudinally convex and transversely flat on upper half; surface reticulate and very minutely, sparsely punctured; vestiture short, sparse, inconspicuous.

Pronotum 1.06 times as long as wide; sides very feebly constricted on posterior third, surface less strongly reticulate, more nearly shining, otherwise as in gracilis.

Elytra 1.6 times as long as wide, 1.8 times as long as pronotum; dorsal profile as in gracilis; elytral bases elevated and acutely costiform, not crenulate; striae moderately impressed, punctures rather large, deep; interstriae slightly less than twice as wide as striae, somewhat irregular, shining, punctures uniseriate. Declivity rather steep, convex; striae 1 strongly, 2 weakly impressed; interstriae feely convex, 1 very slightly elevated, 2 and 3 each armed by a row of rounded granules. Vestiture mostly confined to declivity, but some on disc; consisting of erect interstrial bristles, not flattened, spaced about as in gracilis, with sparse, short, hairlike ground vestiture.

Male.- Similar to female except frontal impression less pronounced on lower half, more nearly convex above; discal interstriae 1,3 , and possibly 5 each with a few obscure granules, closer on 1; declivital granules and bristles a little coarser.

Distribution.- Guatemala to Panama.
GUATEMALA: Cerro Zunil, G. C. Champion. PANAMA: Cerro Punta, Chiriquí, 11-1-64, 1800 m , Nos. 379 , 380. twigs of two tree species, S. L. Wood.

Hosts.- Unidentified trees with large, simple leaves.

Biology.- As in gracilis.
Notes.- The above treatment is based on my series of 11 specimens from Panama. Blandford's series of 4 females differ in having the frons weakly convex between the eyes; the convexity continues as a distinct callus on the median third to the epistomal margin, the lateral areas are impressed and obscurely punctured, and the surface is not reticulate. In addition, the pronotum of Blandford's series is more finely punctured. The differences suggest different taxonomic entities; however, they involve features that might be expected to vary from series to series. Until more material is available for study, only one species should be recognized.

The first of Blandford's four female syntypes, from Cerro Zunil, Guatemala, has been regarded as the type and is here designated as the lectotype of Cnesinus pullus Blandford as indicated above.

## 5. Cnesinus electus Wood

Fig. 85
Cnesinus electus Wood, 1975. Great Basin Nat. 35:23
(Holotype, male: Cartago, Cartago, Costa Rica: Wood Coll.)
Diagnosis.- This species is distinguished from intermedius Schedl by characters mentioned in the above key.

Female.- Length 2.3-2.6 mm, 2.8 times as long as wide; color dark brown, elytra usually reddish brown.

Frons strongly, transversely impressed at level of antennal insertion, convex above, somewhat flattened below this point, epistomal process poorly developed and devoid of granules or tubercles; eyes separated above by half greatest width of an eye; surface of frons rugulose, rather coarsely punctured along lateral margins and on epistoma; vestiture limited to lateral and epistomal areas.

Pronotum 1.1 times as long as wide; dorsal profile as in pullus; surface dull, subshining, more distinctly shining toward base, punctures almost round at base, becoming increasingly elongate anteriorly, occasionally confluent in anterior area. Glabrous.

Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; outline as in gracilis; basal margins raised, feebly crenulate; striae 1 rather strongly, others moderately, not abruptly impressed, punctures small, not confluent except on 1, distinctly, rather strongly impressed; interstriae shining, punctures irregular in size, almost uniseriate. Declivity convex, except moderately impressed between third interstriae; striae feebly impressed, punctures rather small but impressed; interstriae 1 abruptly elevated to apex, about half as high as wide; others almost flat; all interstriae armed by uniseriate rows of moderately large, rounded, setiferous granules, each granule about as high as wide. Vestiture confined to declivity except on interstriae 1 , consisting of rows of rather coarse, moderately long, interstrial bristles, and short, fine, strial hair.

Male.-Similar to female except epistomal callus more prominent.
Distribution. - Costa Rica.
COSTA RICA: Cartago, Cartago, 29-VII-63, 500 m , woody vine, and 2-VIII-63, 1500 m , melastomaceous tree tiwig; Peralta, Cartago, 10-III-64, 500 m , tree seedling: all were taken by me.

Hosts.- Not identified; two tree spp., and one woody vine.

Biology.-All specimens were taken in stems less than 1 cm in diameter from axial tunnels in the pith.

Notes.- The above treatment was based on the type series of 27 specimens.

## 6. Cnesinus intermedius Schedl <br> Fig. 85

Cnesinus intermedius Schedl, 1936, Arch. lnst. Biol. Veget. Río de Janeiro 3:105 (Holotype, male; Turrialba, Cartago, Costa Rica; Schedl Coll.).
Diagnosis.- This species is distinguished from blackmani Schedl by characters mentioned in the above key; in addition, the elytral vestiture is shorter and less abundant, and the elytral and pronotal punctures are slightly smaller.

Female.- Length $1.6-1.9 \mathrm{~mm}, 2.5$ times as long as wide; color of pronotum black, remaining areas dark reddish brown.

Frons convex on upper half of area below upper level of eyes, rather strongly, transversely impressed between levels of antennal insertion and ocular emargination, somewhat flattened below; epistomal callus subcarinate, about equal in length to distance between eyes, its summit partly interrupted at median line, its sculpture and vestiture not conspicuously modified on its upper slope; surface reticulate, punctures minute, shallow, obscure; eyes narrowly separated above by a distance equal to 0.8 (variable, $0.7-1.5$ times; see below) times greatest width of an eye; vestiture sparse, short, rather uniformly distributed except glabrous on median area of upper half.

Pronotum 1.04 times as long as wide; outline as in retifer; surface smooth, shining, punctures deep, rather coarse, broadly oval on basal third, slightly smaller and more elongate anteriorly, separated by distances slightly less than width of a puncture. Glabrous.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; sides almost straight, very slightly wider at base of declivity, rather narrowly rounded behind, declivity occupying posterior third; crenulations on elytral bases distinct, not separate, a slight suggestion of overlapping, each with a rather large puncture on its posterior slope; striae moderately impressed, punctures rather large and deep, largely confluent on 1 ; interstriae weakly convex, as wide as striae, shining but somewhat irregular, the punctures almost uniseriate, near base about half as large as those of striae, smaller posteriorly. Declivity moderately steep, laterally convex, very shallowly sulcate between third interstriae; striae narrower than on disc, punctures rather deep; interstriae rather narrowly convex, 1 , 2 , and 3 about equally elevated (half as high as wide), but 3 higher due to broad declivital impression; each interstriae bearing small, setiferous punctures, those on 2 and 3 very feebly elevated on anterior margins. Vestiture consisting of rows of interstrial bristles, smaller and usually abraded on 1, and a few minute, strial hairs; bristles separated in rows
and between rows by slightly more than half length of a bristle.

Male.-Similar to female except frons much more brightly shining; epistomal callus higher and more extensive, occupying 85 percent of width of frons at level of antennal insertion, subtriangular, lower margins almost straight and upper margins abruptly oblique, slope more gradual above, ornamented on upper slope by dense, dark, reddish brown, ornamental setae of uniformly short length; rudimentary interstrial granules on elytral declivity very slightly larger.

Distribution. Costa Rica to Panama.
COSTA RICA: Volcán, Puntarenas, 11-XIl-63, 1000 m, twigs of a broken branch; Pandora, Limón, 23 -vili$63,50 \mathrm{~m}$, No. 149, twigs of a broken branch; all taken by me. PANAMA: Barro Colorado Island, 24-VII-63.

Host.- Presumably Nectandra sp.
Brology.- The specimens were associated with Sternobothrus sculpturatus (Blandford) on two of the three times they were collected. Evidently both species are host specific to a common tree presumed to be Nectandra sp. This species constructed pith tunnels in the central axis of small branches and twigs.

Notes.- The above treatment was based on 30 specimens, including a male and female examined by Schedl and compared by both Schedl and myself to the type.

In specimens from Limón Province, on the Atlantic slope, the eyes were more widely separated (1.1-1.5 times width of an eve) than those from Puntarenas Province, on the Pacific Slope (0.7-0.9 times). The difference appears too slight and too inconsistent to recognize subspecies based on the material at hand.

## 7. Cnesinus blackmani Schedl Figs. 84, 85

Cnesinus nitidus Blackman, 1943 (nec. Eggers, 1943), Proc. U.S. Nat. Mus. 94:377 (Tampico, Veracruz, Mexico; U.S. Nat. Mus.). Preoccupied.
Cnesinus blackmani Schedl, 1949, Rev. Brasil. Biol. 9:268 (Replacement name)
Cnesinus mexicanus Nunberg, 1956, Ann. Zool., Warsaw 16:207 (Replacement name)
Diagnosis.- This species is allied to intermedius Schedl, but it may be distinguished by characters summarized in the above key and by the additional characters mentioned in the diagnosis of intermedius.

Female.- Length $1.7-1.9 \mathrm{~mm}$, 2.6 times as long as wide; color of pronotum dark brown to black, elytra and other areas a lighter brown to reddish brown.

Frons as in internedius with epistomal callus not as high, but more uniformly elevated, surface móre nearly rugulose; eyes separated by 0.6 times greatest width of an eye (more widely spaced on type).

Pronotum 1.05 times as long as wide; sides straight on basal three-fifths and diverging slightly to widest point two-fifths of length from rather broadly rounded anterior margin; surface shining, smooth, with rather large, deep punctures, punctures broadly oval toward base, more narrowly elongate anteriorly, separated by distances as great or greater than width of a puncture. Glabrous.

Elytra 2.0 times as long as wide, 2.2 times as long as pronotum; basal margins continuously carinate, crenulations not indicated except possibly in lateral area; striae narrow$l y$ impressed, punctures subconfluent; interstriae shining, slightly irregular, almost twice as wide as striae, punctures fine, almost uniseriate. Declivity rather steep, convex with a slight impression between third interstriae; striae 1 strongly, others moderately impressed, punctures smaller and deeper than on disc; interstriae convex, less than half as high as wide, small, setiferous punctures not granulate. Vestiture as in intermedius, declivital bristles twice as long as distance between bristles in rows and between rows.

Male. - Similar to female except frons more nearly shining, epistomal callus higher and longer (not as high or as wide as in intermedius), vestiture evidently more abundant; ornamental setae on epistomal callus much longer and less highly modified than in intermedius; bristles on elytral declivity evidently longer.

Distribution.- Veracruz to Columbia.
MEXICO: Veracruz: Tampico, E. A. Schwarz. GUATEMALA: Livingston, lzabal, H. S. Barber and E. A. Schwarz; Trece Aguas, Alta Verapaz, H. S. Barber and E. A. Schwarz. PANAMA: Porto Belo, Colón, A. Busck. Colombia: La Rivera, Caicedonia, Valles, 18-Vl59, guamo verde, J. Restrepo.

Notes.- The above description was based on the male homotype from Colombia and seven other specimens taken in series with it.
8. Cnesinus punctatus Blandford Fig. 85

Cnesinus punctatus Blandford, 1896, Biol. Centr.-Amer., Coleopt, $4(6): 136$ (Holotype, female; Volcán de

Chiriquí, Chiriquí, Panama; British Mus. Nat. Hist.)
Diagnosis.- This distinctive species is somewhat allied to niger, but the stout body

Fig. 84. Cnesinus and Bothrosternus spp.: 1-2, C. cubensis; 3-4, C. setulosus, male; 5, C. robai; 6, C. setulosus, female; 7-8, C. costulatus, female; 9-11, B. foteatus; 12-13, C. blackmani, female. (After Blackman 1943: pl. 15.)
form and other characters mentioned in the key serve to distinguish it.

Female. - Length $2.3-3.0 \mathrm{~mm}, 2.1$ times as long as wide; color very dark reddish brown.

Frons as in internedius, except epistomal callus slightly higher on its lateral thirds, median third reduced, almost obsolete, and eyes separated by a distance equal to 2.3 times greatest width of an eye; vestiture sparse, of moderate length, only one row of setae on upper slope of epistomal callus.

Pronotum 1.0 times as long as wide; widest at middle, sides weakly arcuate on basal twothirds, rather broadly rounded in front; surface smooth, shining, punctures small, deep, broadly oval posteriorly, more elongate anteriorly, separated by distances equal to one to three times width of a puncture. Glabrous.

Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; sides very feebly arcuate on basal two-thirds to declivital margin, broadly rounded behind; basal margins slightly elevated, acutely costate, with a submarginal row of moderately large punctures on posterior slope of costa; striae moderatelly impressed, particularly 1, punctures rather small, not confluent except on 1 ; interstriae broadly convex, at least twice as wide as striae, smooth, shining, with sparse, transverse lines, punctures small, irregular in size, confused. Declivity moderately steep, broadly convex with a slight impression between third interstriae; striae not impressed, punctures moderately large, deep; interstriae 1 abruptly, rather weakly elevated, ascending gradually laterally to moderately convex interstriae 3,2 and 3 each armed by a sparse row of moderately large, rounded tubercles, lateral interstriae also armed posteriorly by a few tubercles. Vestiture confined to declivity, consisting of interstrial rows of coarse, pointed bristles and a few short, fine, ground setae; each bristle at least twice as long as distances between bristles within rows and between rows; sutural row of bristles much shorter.

Male.- Similar to female except epistomal callus much larger, equal to 0.6 width of frons at level of antennal insertion, acutely subprecipitous on its lower margin, upper slope gradual and densely covered by reddish ornamental setae of uniformly short length.

Distribution.- Puebla to Panama.

MEXICO: Puebla: 10 km NE Teziutlan, 2T-VI-53, 450 m No. 54 , cut woody vine; 12 km W Villa Juárez, 25 -VI53, No. 36, twigs of a small cut tree. COSTA RICA: Escasu, San José, 2-X-63, 1300 m , No. 215 , Guazuma ulmifolia twigs; San Ignacio de Acosta, San José, 5-VII-6:3, No. 28, broken branch; all by S. L. Wood. PANAMA: Volcán de Chiriquí, Chiriqui, G. C. Champion.
Hosts.-Guazuma ulmifolia, two other trees, and a woody vine.

Biology. - Similar to the preceding species.

Notes.- The above descriptions are based on 38 specimens, including a female homotype compared by me to the female type.

## 9. Cnesinus niger Wood

Fig. 85
Cnesinus niger Wood, 1967, Great Basin Nat. 27:83 (Holotype, male; Cerro Punta, Chiriquí, Panama; Wood Coll.)
Diagnosis.- This species is allied to punctatus Blandford and electinus Wood; the above key summarizes the distinguishing characters.

Female.- Length 2.0-2.5 mm, 2.6 times as long as wide; color almost black.

Fronx convex above, transversely impressed at level of ocular emargination; epistomal callus as in intermedius; surface subreticulate, shining, punctures obscurely evident below upper level of eyes; vestiture rather sparse and inconspicuous as in females of related species; eyes separated by a distance about equal to 2.5 times width of an eye.
Pronotum 1.04 times as long as wide; widest just behind middle; surface almost smooth and shining, punctures rather coarse, deep, close, almost round at base, more elongate anteriorly, separated by distance less than half width of a puncture except on median line, rarely confluent. Glabrous behind, a few short setae on anterior third (usually abraded).

Elytra 1.7 times as long as wide, 2.0 times as long as pronotum; outline as in intermedius; basal crenulations obscurely indicated, not isolated; striae impressed, punctures moderately large, deep, mostly separated from one another; interstriae as wide as striae, punctures fine, shallow, not strongly confused, surface subshining. Declivity rather steep, convex, rather weakly impressed between third interstriae; interstriae

1,2 , and 3 rather narrowly convex, 2 and 3 each bearing a row of fine granules. Vestiture confined to declivity, consisting of interstrial rows of moderately long, stout bristles, except missing on lower two-thirds of 1 : each bristle twice as long as distance between bristles within and between rows.

Male.-Similar to female except epistomal callus almost reaching lateral margins, sharply defined along its lower margin, upper slope gradually and densely covered by ornamental setae, with a median glabrous, triangular area on lower half below.
Distribution.- Panama.
PANAMA: Cerro Punta, Chiriquí, 11-1-64, 1800 m . Nos. $377,379,380,388$, twigs of three tree species. S. L.
Wood. Wood.

## Biology. - Similar to intermedius.

Notes. - The above treatment was based on the type series of 42 specimens.

## 10. Cnesinus electinus Wood Fig. 8.5

Cnesinus electinus Wood, 1967, Great Basin Nat. 27:82 (Holotype, male: Mazamitla, Jalisco, Mexico: Wood Coll.)
Diagnosis. - This species is allied to niger Wood and myelitus Wood, but it may be distinguished by characters summarized in the above key.
Female.- Length 2.1-2.5 mm, 2.7 times as long as wide; color dark brown, the elytra usually lighter.

Frons transversely impressed at level of ocular emargination, convex above, flattened below this point; epistomal callus weakly developed on more than median half; convex area almost smooth, subshining, impunctate except at sides and above; vestiture scanty, limited to lateral and epistomal areas; eyes separated by a distance slightly more than twice width of an eye.

Pronotum 1.1 times as long as wide; sides almost straight and parallel on anterior twothirds, very slightly wider in front of middle, anterior margin broadly rounded; surface smooth and shining, with rather numerous, minute points and moderately large, rather deep, oval punctures, punctures separated by about one to three times their own diameters, none confluent. Vestiture sparse, confined to marginal areas.

Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; basal crenulations evident but rather poorly formed; striae impressed, punctures moderately large, deep; interstriae almost twice as wide as striae, convex, punctures small and staggered in indefinite, uniseriate rows, punctures on 2 , and near declivity on 1,3 and 4 granulate. Declivity steep, weakly impressed between third interstriae; striae 1 strongly impressed, others not impressed, punctures moderately large and deep; interstriae 1 moderately elevated, 3 convex, 1 with fine punctures, 2 and 3 with moderately large, rounded granules. Vestiture almost restricted to declivity, consisting of rows of erect bristles on all interstriae except 1 , each bristle one to two times as long as distance between rows of bristles.

Male.- Similar to female except epistomal callus broad, weakly elevated, lower margin abrupt, a small, triangular, median area impunctate and glabrous, remaining area densely covered by erect, reddish ornamental bristles.

Distribution.- Jalisco.
MEXICO: Jalisco: Mazamitla, 22-VI-65, 2400 m . No. 93, twigs of a small tree. S. L. W'ood.

Biology. - Similar to intermedius.
Notes. - The above treatment was based on the 30 specimens in the type series.

## 11. Cnesinus myelitis Wood

Cnesinus myelitis Wood, 1967, Great Basin Nat. 27:84 (Holotype, male; Teziutlan, Puebla, Mexico: Wood Coll.)
Diagnosis. - This species is distinguished from electinus Wood by characters summarized in the above key.

Female.- Length 2.0-2.4 mm, 2.4 times as long as wide; color dark brown.

Frons transversely impressed at level of ocular emargination, convex above and flattened below this point; convex area minutely, transversely aciculate, lower area subreticulate; epistomal callus clearly evident but weakly elevated on median third; eyes separated by about twice width of an eye.

Pronotum 1.05 times as long as wide; sides feebly arcuate on basal two-thirds, very slightly wider in front of middle, anterior margin rather broadly rounded; surface subshining, evidently with very minute points
and moderately large, shallow, oval punctures, punctures largely confluent on anterior half, on posterior half separated by distances about equal to width of a puncture. Subglabrous.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides straight and parallel on anterior two-thirds, rather broadly rounded behind; basal margins elevated, crenulations indistinctly marked; striae rather strongly impressed, punctures moderately large, deep; interstriae about twice as wide as striae, convex, punctures uniseriate, fine in middle area, a few subcrenulate toward base, forming rather large, rounded granules on posterior third of 1 and posterior fourth of 2 and 3. Declivity rather steep, convex, with a shallow impression between third interstriae; striae 1 strongly impressed, others not impressed; interstriae 1 broadly convex, weakly elevated, 3 weakly convex, higher than 1, 1 punctured, 2 and 3 each armed by a row of rather large, rounded granules. Vestiture almost limited to declivity, except interstriae 1 on disc; consisting of interstrial rows of erect bristles, absent on lower three-fourths of 1 ; each bristle about one and one-half to two times as long as distance between rows.

Male.- Similar to female except epistomal callus larger, broad, slightly elevated, covered by a brush of rather long, erect, reddish bristles, entire callus setiferous (smaller and less strongly elevated than in punctatus), its lower median margin armed by a small tubercle.

Distribution.- Puebla.
MEXICO: Puebla: 10 km NE Teziutlán, Puebla, 27-Vl-53, 1500 m , No. 54 , woody vine, S. L. Wood.

Biology.- Similar to intermedius.
Notes.- The above treatment was based on the type series of 18 specimens.

## 12. Cnesinus bicornus Wood Fig. 86

Cnesinus bicornus Wood, 1967, Great Basin Nat. 27:80 (Holotype, female; Morelia, Michoacán, Mexico; Wood Coll.
Diagnosis.- This species is distinguished from elegans Blandford by characters summarized in the above key.

Female.- Length $3.3-3.8 \mathrm{~mm}, 2.5$ times as long as wide; color dark reddish brown.

Frons rather deeply concave from eye to eye from vertex to epistoma, lateral margins
acute below eye; epistoma armed by a pair of large, pointed, conical spines, each longer than half width of eye; concavity on lower half with a pair of lateral calluses; surface substrigose-reticulate, with small, rather sparse, obscurely granulate punctures; vestiture fine, obscure, except a row of rather long, erect, hairlike bristles on lateral margin; eyes separated by 2.7 times width of an eye.

Pronotum 1.1 times as long as wide; sides almost straight on basal two-thirds, very slightly wider in front of middle, broadly rounded in front; surface longitudinally strigose, punctures usually not evident, grooves dull, ridges shining; median line evident on posterior half. Vestiture hairlike, inconspicuous or absent except on all marginal areas.

Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel to declivital base, rather broadly rounded behind; basal margins poorly elevated, crenulations evident but obscure; striae narrowly, not strongly impressed, punctures small, impressed; interstriae three or more times as wide as striae; subcrenulate toward base, remaining surface shining, not clearly punctured, irregular, with small rounded granules in somewhat indefinite uniseriate rows. Declivity rather steep, convex, except flattened between third interstriae; striae 1 strongly, 2 moderately, 3 not impressed; interstriae subshining, weakly convex, about four or more times wider than strial punctures, each interstriae with a median row of rather large rounded granules. Vestiture hairlike, more abundant but not longer on declivity; consisting of median rows of fine, erect interstrial hair, and more abundant, almost equally long, semirecumbent hair; longest setae about equal to distance between median rows; somewhat coarser on declivity.

Male.-Similar to female except frontal excavation slightly shallower and less extensive; epistomal callus developed but unarmed, bearing one transverse row of bristles on its upper slope.

Distribution.- Michoacán to Morelia.
MEXICO: Michoacán: Morelia, 15-VI-65, 2300 m , No. 58, stems of a large herb, S. L. Wood. Morelos: Tlayacapan, I8-X-80, S-119, T. H. Atkinson.
Biology. - The egg tunnels were in the pith of the central axis of stems up to 3 cm in diameter in an herbaceous plant 2-3 m tall.

Eggs and young larvae were scattered at random toward the ends of the biramous egg gallery.

Notes.- The above treatment was based on the type series of 45 specimens.

## 13. Cnesinus degener Wood

Fig. 85
Cnesinus degener Wood. 1968, Great Basin Nat. 28:105 (Holotype, female; Matías Romero, Oaxaca, Mexico, Wood Coll.).
Diagnosis.- This species is intermediate between bicornus Wood and elegantis Wood; the size and other characters summarized in the above key serve to distinguish it.

Female.- Length $2.0-2.3 \mathrm{~mm}, 2.4$ times as long as wide; color dark reddish brown.

Frons as in elegantis except impression slightly deeper and more feebly convex, almost flat to well above upper level of eyes; details of sculpture, epistomal tubercles, and vestiture as in elegantis.
Pronotum 1.03 times as long as wide; as in elegantis except sculpture slightly coarser and with fine, sparse, hairlike setae over entire surface.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; sides almost straight and subparallel on basal two-thirds, rather broadly rounded behind, declivity occupying almost posterior half; basal crenulations distinctly formed on median third, becoming a continuous, acute costa laterally; striae slightly impressed, punctures larger than in elegantis, distinctly impressed, subconfluent on 1 ; interstriae less than twice as wide as striae, irregular, punctures moderately large, rather abundant, confused, an indefinite median row on each finely granulate. Declivity more gradual than in related species, convex, with impression between third interstriae not as deep as in elegantis; striae not impressed, punctures rather small, deep; interstriae 1 abruptly, rather weakly elevated, 3 slightly, broadly elevated, 2 and 3 each armed by a median row of fine granules. Vestiture rather abundant on disc and declivity, consisting of interstrial rows of erect, very stout bristles, each very slightly longer than distances between bristles within rows and between rows, and more abundant, semirecumbent, fine to very stout strial and interstrial ground setae,
each about a third as long as the erect bristles.

Male.-Similar to female except frontal impression not quite as deep, epistomal tubercles absent.

Distribution.- Oaxaca to Veracruz.
Mexico: Oaxaca: 11 km N Matías Romero, $24-\mathrm{Vl}-$ $67,200 \mathrm{~m}$. No. 95 , woody vine, and 39 km N Matias Romero, 29-V1-67, 140 m , No. 121, Seriania; all by S. L. Wood. Veracruz: Cordoba, A. Fenyes.

Hosts.-Serjania sp., and another woody vine.

Biology.- Specimens were removed from the central axis of stems less than 5 mm in diameter. The habits appeared similar to most other species in the genus.

Notes.- The above treatment was based on the type series of 10 specimens.

## 14. Cnesinus paleatus Blandford

Cnesinus paleatus Blandford, 1896, Biol. Centr.-Amer., Coleopt. 4(6):138 (Holotype, female; El Tumbador, Guatemala; British Mus. Nat. Hist.)
Diagnosis.- This species is distinguished from degener Wood by the much larger size, by the much longer, more slender, interstrial bristles, by the much more deeply impressed elytral declivity, and by other characters.

Female.- Length $2.8 \mathrm{~mm}, 2.5$ times as long as wide; color dark reddish brown.

Frons as in elegantis except epistomal setae in transverse row much stouter, closer. Eyes separated by 2.3 times width of an eye.

Pronotum 1.08 times as long as wide; outline and sculpture as in elegantis except impressed longitudinal grooves coarser, very slightly wider than interspaces; vestiture largely abraded, fine, hairlike on disc, course at sides and anteriorly, long anteriorly.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; outline as in elegantis but stouter; basal margins slightly elevated, crenulations obscurely indicated; striae rather weakly impressed, punctures moderately course, deep, not confluent; interstriae twice as wide as striae, punctures very fine, rather abundant, confused, each interstriae with a uniseriate row of fine, rounded granules. Declivity steep, impressed between third interstriae similar to degener but slightly deeper; sutural striae slightly more strongly impressed; interstriae 1 weakly elevated, 2 almost flat, lateral area ascending to 4 ;
interstrial punctures moderately large, uniseriate, not at all granulate on 1-3, very finely granulate laterally. Vestiture largely abraded on disc of type; ground setae stout, four to six times as long as wide, their length up to twothirds interstrial width; erect, uniseriate bristles very course, long, many at least twice as long as width of one interstriae, shorter on declivity but apparently broken by wear.

Distribution.- Guatemala.
guatemala: El Tumbador, G. C. Champion.
Note.- The above description was prepared from the female holotype. Nothing is known of the habits of this species.

## 15. Cnesinus brighti Wood

Cnesimus brighti Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):6 (Holotype, female; 9 miles or 14 km SE Teopisca on Highway 24, Chiapas. Mexico; Canadian National Coll.)
Diagnosis.- This species is distinguished from elegantis Wood by the smaller size, by the smaller female epistomal tubercles, by the coarser frontal vestiture, by the coarser pronotal striations, by the fine hair covering the pronotum, by the less strongly impressed striae, and by the discal pubescence.

Female.- Length 2.2-2.6 mm, 2.7 times as long; color rather dark reddish brown.

Frons as in elegantis but with epistomal denticles much smaller and basally contiguous, vestiture stouter and slightly more abundant.

Pronotum 1.1 times as long as wide; striations coarser and wider than either elegantis or coracinus, punctures not evident. Vestiture of rather abundant, fine, short hair on disc, longer and coarser anteriorly.

Elytra 1.9 times as long as wide; as in elegantis except vestiture extends to base of disc, consisting of rather abundant, short, coarse, confused setae of about uniform length, not longer on declivity, each seta about equal in length to width of an interstriae.

Male.- Similar to female except epistomal tubercles absent.

Distribution.- Chiapas.
MEXICO: Chiapas: Lagos des Colores, 17-V-69, D. E. Bright: 9 miles or 14 km SE Teopisca, 14, 30-V-69, D. E. Bright.

Notes.- The above treatment was based on the type series of 70 specimens.

## 16. Cnesinus elegans Blandford

Fig. 85
Cnesinus elegans Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6):140 (Lectotype, female: Cerro Zunil, Guatemala; British Mus. Nat. Hist., present designation)
Diagnosis.- This species is distinguished from the closely related elegantis Wood by characters summarized in the above key.

Female. - Length $2.4-2.8 \mathrm{~mm}, 2.9$ times as long as wide; very dark reddish brown, the pronotum often almost black.

Frons convex above level of ocular emargination, lower area moderately concave, lateral margins acute; epistomal callus poorly developed, armed by two small tubercles, each as high as wide, tubercles separated by a distance about equal to three times basal width of a tubercle; surface minutely reticulategranulate, fine punctures obscure; vestiture consisting of moderately abundant, coarse, rather long setae across upper margin of epistomal callus and on lateral margins to upper level of eyes; eyes separated by a distance equal to 1.7 times width of an eye.

Pronotum 1.17 times as long as wide; sides straight to widest point two-thirds length from base, then rather broadly rounded in front; surface shining, punctures dull, punctures moderately large, rather deep, about twice as long as wide, most marginally confluent with at least one other puncture. Vestiture confined to marginal areas.

Elytra 1.9 times as long as wide, 2.0 times as long as pronotum; sides almost straight and parallel to declivital base, rather narrowly rounded behind, declivity confined to posterior fourth; crenulations on basal margins poorly formed; striae shallowly impressed, 1 stronger, punctures rather small, moderately deep, confluent on 1 ; interstriae 1 and 2 as wide as striae, others wider, 1 and 2 weakly convex, surface shining, punctures fine, obscure, uniseriate; a few granules on interstriae near declivity, two or three extend to middle of dise on 3 . Declivity rather steep, convex, with a shallow impression between third interstriae; striae 1 impressed, others not impressed, punctures small, rather deep; interstriae 1 abruptly elevated, almost half as high as wide, 3 weakly convex, 1 punctured, 2 and 3 each with a row of small, rounded
granules. Vestiture largely confined to declivity (about a dozen bristles on disc) consisting of interstrial rows of erect bristles and fine, sparse, semirecumbent strial and interstrial hair; each bristle up to twice as long as distance between rows of bristles.
Male.- Similar to female except epistomal callus somewhat reduced and unarmed by tubercles; declivital impression evidently deeper.

## Distribution.- Puebla to Venezuela.

MEXICO: Chiapas: 10 km SE Teopisca, 18-V-69, Arbutus, D. E. Bright. Puebla: 10 km NE Tezuitlán, 27--V1$53,1600 \mathrm{~m}$, No. 44 , and 2-VII-67, No. 154, woody vine. and No. 142, in Rubus sp., S. L. Wood. Veracruz: Jalapa, Höge; 1 km west Las Vigas, 5 -VII-67, No. 160, in Alnus twigs, S. L. Wood; Oaxaca: 10 km S Huajuapan, 16-VI-67, No. 45, Seriania, S. L. Wood. guatemala: Cerro Zunil, G. C. Chámpion. HONDURAS: Zamorano, Morazán, 18-IV-64, No. 511, broken twigs, S. L. Wood. PaNAMA: Volcán, Chiriquí. Schedı (1940:331) adds Panama and Venezuela without further data.

Hosts.- Arbutus sp., Rubus sp., Seriania sp., another woody vine, and a shrub.

Biology.-As in preceding species.
Notes. - The above descriptions were based on 115 specimens, including the female lectotype from Cerro Zunil, Guatemala, a female lectoparatype from Volcán Chiriquí, Panama, a male lectoparatype from Jalapa, Mexico, and a male and female from Zamorano, Honduras, compared by both Schedl and myself to a lectoparatype. The entire type series was examined, but comparisons to my material were indirect.
Blandford's female syntype, used for his Figure 11 on Table VI, from Cerro Zunil, was selected from the type series of six specimens and is here designated as the lectotype of Cnesinus elegans Blandford.

## 17. Cnesinus theocallus Bright

Cnesinus theocallus Bright, 1972, Canadian Ent. 104:1493 (Holotype, feniale; 24 km or 15 miles S Valle Nacional, Oaxaca, Mexico; Canadian Nat. Coll., 12607)
In all probability theocallus Bright is a synonym of elegans Blandford. The only difference is in the frontal width separating the eyes. This distance in elegans varies from 1.0-1.5 times the width of an eye, except for one Costa Rican specimen that is 0.90 times as wide; the holotype of theocallus is 0.46 times as wide. In the absence of supporting characters, and, because of the unavailability
of material from southern Mexico, I am reluctant to recognize this form as a species.

Only the type series of three specimens of theocallus is known from Oaxaca: 24 km or 16 miles S Valle Nacional, 20-V-71, 1300 m , D. E. Bright. The holotype is 2.7 mm in length.

## 18. Cnesinus elegantis Wood

Cnesimus elegantis Wood, 1967, Great Basin Nat. 27:79 (Holotype, female: Volcán Zumil, Quezaltenango, Guatemala; Wood Coll.)
Cnesinus zapotecus Bright, 1972, Canadian Ent. 104:1493 (Holotype, female; 5 km or 3 miles N Suchixtepec, Oaxaca, Mexico; Canadian Nat. Coll.); Wood, 1973, Great Basin Nat. 33:174. Synonymy
Diagnosis. - This species is distinguished from the closely related elegans Blandford by characters summarized in the above key.

Female.- Length $3.0-3.4 \mathrm{~mm}, 2.7$ times as long as wide; color brown.
Frons strongly, transversely impressed at level of antennal bases, convex above, impressed area shallowly concave, with a pair of sublateral calluses on either side of deepest point of impression; epistomal callus evident, armed by a pair of rather widely placed, large pointed tubercles larger than those of elegans but smaller than in bicornus; surface reticulate, minutely, sparsely punctured; vestiture fine, hairlike, mostly on marginal areas; eyes separated by a distance equal to twice greatest width of an eye.

Pronotum 1.06 times as long as wide; sides almost straight posteriorly, widest in front of middle; surface with closely set, deep, elongate punctures, most at least partly longitudinally confluent. Glabrous.

Elytra 1.8 times as long as wide, 1.9 times as long as pronotum; sides straight and subparallel to declivital base, rather broadly rounded behind; basal crenulations low, obscure; striae inoderately impressed, punctures rather small, deep, interstriae twice as wide as striae, punctures small, variable in size, rather confused. Declivity rather steep, rather strongly impressed between third interstriae; striae not impressed except 1, punctures clearly, rather deeply impressed; interstriae 1 moderately elevated, 2 almost flat, ascending laterally, wider than 1 or 3 , all armed by a few fine, rounded, irregularly placed granules. Vestiture largely confined to
declivity, consisting of long, rather fine interstrial bristles and shorter strial and interstrial hair; longest bristles equal in length to combined width of interstriae 2 and 3 .

Male.-Similar to female except frontal callus slightly more prominent and unarmed.

Distribution.- Chiapas to Guatemala.
MEXICO: Chiapas: 11 km E San Cristóbal, 26 -V-69, Arbutus, D. E. Bright. GUATEMALA: Volcán Zunil, Quezaltenango, 27-V-64, 1000 m , No. 629, Quercus twigs, S. L. Wood.

Host.-Arbutus sp., Quercus sp.
Biology. - Similar to preceding species.
Notes.- The above treatment was based on the type series of 33 specimens of elegantis, on the holotype and six paratypes of zapotecus, and on one other specimen.

## 19. Cnesinus coracinus Wood

Cnesinus coracimus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):6 (Holotype, female: 5 miles or 8 km S Simojovel, Chiapas, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from elegantis Wood by the smaller size, by the stouter body, by the finer, closer female epistomal tubercles, by the finer frontal vestiture, by the slightly coarser pronotal striation, by the coarser strial punctures, and by the shorter, stouter declivital setae.

Female.- Length 2.1-2.3 mm, 2.5 times as long as wide; color black.

Frons as in elegantis except epistomal tubercles smaller, much closer, concavity not quite as deep, extending slightly nearer upper level of frons, surface obscurely punctured, vestiture finer, less abundant.

Pronotum 1.04 times as long as wide; much as in elegantis but with striations more distinctly punctured and wider.

Elytra 1.6 times as long as wide; strial punctures slightly larger and deeper than in elegantis, interstriae feebly convex; declivity less strongly impressed, interstriae each with a row of granules. Vestiture confined to declivity, consisting of sparse, short, ground vestiture of rather fine hair, and rows of interstrial bristles; each bristle about as long as distance between rows, more closely spaced within a row.

Distribution.- Chiapas.
MEXICO: Chiapas: 5 miles or $8 \mathrm{~km} S$ Simojovel, 4 -VII-69, D. E. Bright.

Notes.- The above treatment was based on the type series of six specimens.

## 20. Cnesinus garrulus Schedl

Cnesinus garrulus Schedl, 1940, An. Esc. Nac. Cienc. Biol., Mexico 1:332 (Holotype, female; Yautepec, presumably Morelos, Mexico; Schedl Coll.)
Diagnosis.- This species is distinguished from gibbulus Wood by the median epistomal tubercle, by the oval pronotal punctures that are not extended by strigose lines, and by the obsolete punctures on declivital striae 1-3.

Female.- Length $2.3 \mathrm{~mm}, 2.6$ times as long as wide; color rather dark reddish brown.

Frons convex above, broadly, rather deeply, concavely impressed from slightly below upper level of eyes to epistomal area; submarginal area of epistoma slightly elevated, ornamented by a uniseriate, transverse row of stout bristles, with a pointed median tubercle about equal in height and width to twice diameter of a facet of eye; vestiture sparse, consisting of transverse row mentioned above, and a few hairs on lateral margins.

Pronotum as in gibbulus except punctures oval, each about twice as long as wide, without strigose extensions, rarely confluent, separated by distances equal to or slightly less than diameter of a puncture; surface smooth, shining. Glabrous except at margins.

Elytra outline as in gibbulus; basal margins more strongly elevated; striae distinctly, rather weakly impressed, punctures small, impressed; interstriae two and one-half times as wide as striae, feebly convex, shining, almost smooth, punctures minute, a few obscure points also indicated. Declivity rather steep, convex except flat on median half of lower two-thirds; punctures obsolete on striae $1-4$; upper half of interstriae 2 and 3 each with a row of very fine granules. Vestiture abraded, a few broken setae on margins of declivity.

## Distribution.- Morelos?

The holotype is labeled "Yautepec, Flohr; Yaw"; not Uecatan as reported by Schedl. It is presumed this locality is Yautepec, Morelos.

Notes.- The above treatment was based on the holotype.

## 21. Cnesinus quaesitus Schedl

Cnesinus quaesitus Schedl, 1940, An. Esc. Nac. Cienc. Biol., Mexico 1:331 (Holotype, female; "Tibayes," Mexico; Schedl Coll.)
Diagnosis.- This species is distinguished from the almost identical gibbulus Wood by the distinctly larger size, by the much less strigose punctures of the pronotum, and by the different sculpture of the frons.

Female.- Length $3.0 \mathrm{~mm}, 2.6$ times as long as wide; color dark reddish brown.

Frons as in gibbulus except eyes separated by 1.6 times width of an eye ( 2.4 times in gibbulus), central area smooth and brightly shining; epistomal elevation with its flattened area larger, its upper slope more gradual.

Pronotal punctures feebly strigose (about twice as long as wide), rarely if ever confluent, their size and spacing as in gibbulus. Elytra as in gibbulus.

Distribution.- "Tibayes," Mexico.
Notes.- The above treatment was based on the female holotype. The label bears one word very poorly written in script in washable ink, presumably "Tibayes." Because I am unable to find such a locality on any map or in a gazetteer, I suggest that it could be a contraction or misspelling or Tacubaya, a location in the Distrito Federal.

## 22. Cnesinus gibbulus Wood Fig. 86

Cnesinus gibbulus Wood, 1968, Great Basin Nat. 28:100 (Holotype, female; Villa Mills, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from gibbosus Wood by characters mentioned in the above key.

Female.- Length $2.4-2.8 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown.

Frons transversely, concavely impressed at level of antennal bases, convex above, lower area largely occupied by a large, median, rhomboidal (subtriangular in some specimens) elevation, wider than long, with its lower sides precipitous, its upper two sides closely pubescent, elevation near but not attaining epistomal margin; flattened surface of elevation and convex surface above very minutely, transversely substrigose, lateral areas and vertex with fine punctures; vestiture other than brush of elevation, sparse, inconspicuous, limited to lateral areas.

Pronotum 1.06 times as long as wide; sides straight and parallel on basal two-thirds, broadly rounded in front; punctures rather small, deep, mostly less than twice as long as wide, about a third of them longitudinally confluent; scanty vestiture limited to anterior area and margins.

Elytra 1.6 times as long as wide, 1.9 times as long as pronotum; sides almost straight and parallel to declivital base, broadly rounded behind; bases of interstriae 2 and 3 with a few obscure marginal and submarginal crenulations; striae impressed, punctures rather small, individually, rather deeply impressed; interstriae about twice as wide as striae, marked by a few irregularly placed transverse lines, punctures small, shallow, in rather indefinite rows. Declivity convex, steep; striae 1 rather strongly impressed, others less strongly impressed, impression re duced toward apex; interstriae moderately convex, with small, deep punctures. Vestiture largely confined to declivity, fine, hairlike, rather long, mostly in interstrial rows except absent on sutural interstriae.

Male.-Similar to female except frontal elevation reduced to a low, transverse, medially impressed ridge, pubescence equal to female; transverse frontal impression longer and with a pair of small, rounded, lateral calluses; elytral declivity more strongly impressed medially.

## Distribution.- Costa Rica.

COSTA RICA: Villa Mills on Cerro de la Muerte, Cartago, 26-V1-66, 3100 m , No. 8, Quercus twigs, S. L. Wood.

Biology.- Essentially as in other species of this genus.

Notes.- The above treatment was based on the type series of 16 specimens.
23. Cnesinus gibbosus Wood Fig. 86

Cnesinus gibbosus Wood, 1968, Great Basin Nat. 28:101 (Holotype, female; Volcán Poas, Heredia, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from the closely allied gibbulus Wood by characters summarized in the above key.

Female. - Length $2.8-3.5 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown.

Frons strongly, transversely impressed just above level of antennal bases, convex above,

Fig. 86. Cnesinus spp., heads: 12-13, bicormus; 14, gihhulus: 15, gibbosus; 16, lecontei; 17, perplexus. (After Wood 1968:93.)
flattened below, with median half occupied by an abruptly elevated, flat, pentagonal elevation reaching almost to epistomal margin, upper two sides ornamented by a row of stout ornamental bristles, process higher and narrower than in gibbulus; upper area almost smooth, with a few punctures and inconspicuous setae in lateral areas and on vertex.

Pronotum 1.06 times as long as wide; sides almost straight and parallel on more than basal half, broadly rounded in front: punctures fine, deep, each three or four times as long as wide, about two-thirds of them longitudinally confluent; vestiture inconspicuous except at margins, but covering entire surface.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; sides straight and parallel to base of declivity, rather broadly rounded behind; basal margins not elevated, several small marginal and submarginal tubercles present; striae impressed, punctures small, obscurely impressed; interstriae about twice as wide as striae, dull, punctures small, rather numerous, confused. Declivity shallowly impressed between third interstriae, steep: striae impressed, punctures small, deep; interstriae convex, 1 with a row of fine punctures, 2 and 3 almost impunctate, each with a row of closely set interstrial bristles arising from mesal margin. Vestiture mostly confined to declivital area, consisting of interstrial rows of long, fine hair and some short, fine, recumbent hair; interstrial bristles absent on 1 ; longest bristles almost equal to twice distance between rows.

Male.-Similar to female except frontal elevation reduced to a broad, transverse, medially impressed callus, its upper margin ornamented by a straight row of reddish bristles; frontal impression longer deeper, concave, with a pair of rounded lateral calluses.
Distribution.- Costa Rica.
COSTA RICA: Volcán Poas, Heredia, l4-VII-63, 2500 m, No. 45, woody vine, S. L. Wood.

Biology.- Presumably as in the preceding species. The entire pith region of a stem 0.5 cm in diameter had been consumed by the young adults.

Notes. - The above treatment was based on the type series of 31 specimens.

## 24. Cnesinus lecontei Blandford <br> Fig. 86

Cnesinus lecontei Blandford, 1896, Biol. Centr. Amer. Coleopt. 4(6):138 (Lectotype, male: Quiché Mits., El Quiché, Guatemala; British Mus. Nat. Hist., present designation).
Diagnosis. - This large, distinctive species is not closely related to any other Central American species. The size, the abundant, rather short, almost hairlike vestiture, and the very different male frons distinguish it from allied species.
Female.- Length $2.7-3.3 \mathrm{~mm}, 2.1$ times as long as wide; color dark brown.

Frons broadly, very shallowly concave from epistomal margin to upper level of eyes; epistomal margin weakly elevated, shining, remaining surface finely reticulate, with small, obscure punctures; vestiture consisting of rather sparse, uniformly distributed, short bristles; eyes widely separated.

Pronotum 0.92 times as long as wide; widest at middle, sides rather strongly arcuate, rather strongly constricted just before broadly rounded anterior margin; surface closely, rather finely, longitudinally strigose, individual punctures obscure, ridges smooth, shining, impressions irregular, subshining. Vestiture consisting of minute, fine hair over entire surface.

Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; sides weakly arcuate to declivital base, rather narrowly rounded behind, declivity occupying posterior third; crenulations on basal margins low, distinct on median third, with one or two irregular rows of small, submarginal crenulations at bases of interstriae 2-4; striae narrowly, deeply impressed, punctures small, obscure; interstriae about three times as wide as striae, surface rather finely granulose, punctures obscure. Declivity moderately steep, broadly convex; essentially as on disc, with interstriae somewhat narrower, their granules less abundant and slightly larger; entire surface reticulate. Vestiture fine on disc, rather coarse on declivity; consisting of interstrial rows of erect bristles, each bristle slightly shorter than distances between adjacent bristles within and between rows, and more abundant ground vestiture about half as long as bristles.

Male.- Similar to female except frons less deeply impressed, lower two-thirds with a
large, median, subtriangular, densely, minutely pilose area three-fourths as wide as frons below level of antennal insertion, upper third immediately above pilose area glabrous, subshining, minutely etched; longer (but short) setae confined to marginal areas.

Distribution.- Guatemala to Panama.
GUATEMALA: Quiché Mountains, El Quiché, G. C. Champion. COSTA R1CA: San lgnacio de Acosta, 5-V11$63,1600 \mathrm{~m}$, No. 26; San lsidro del General, 13-XIl-63, 1000 m, No. 312, Croton sp.; San José, 22-X-63, 1300 m , No. 167; all from San José Province, in Croton gossypiifolia (exception noted), by S. L. Wood. PANAMA: Volcán de Chiriquí, Chiriquí, G. C. Champion.

Hosts.- Croton gossypiifolia, and Croton sp.

Biology.- This species is very common in fence-row plantings of the host tree at elevations of $1000-2000 \mathrm{~m}$. It bores in the pith of recently cut or broken branches about 1-4 cm in diameter. From the entrance tunnel the female parent excavates an axial tunnel $1-6 \mathrm{~cm}$ or more, in either or both directions. Eggs are scattered near the ends of the tunnel and the larvae extend the tunnel along the axis of the branch. The larvae feed communally and almost never make individual tunnels.

Notes.- Of Blandford's original series of nine specimens, only six were in the British Museum (Natural History) in July 1964. One of these, a male, was selected and is here designated as the lectotype of the species. The lectotype, my male homotype, and the other Costa Rican specimens were used to prepare the above description. For this study 77 mounted specimens and more than a 100 preserved specimens were examined.

## 25. Cnesimus perplexus Wood Fig. 86

Cnesinus perplexus Wood, 1968, Great Basin Nat. 28:102 (Holotype, male; San Ignacio de Acosta, San José, Costa rica; Wood Coll.)
Diagnosis. - The row of small asperities on the anterolateral angles of the pronotum distinguish this species from all other Central American species of the genus. It is closely related to robai Blackman and coffeae Schedl, both from Colombia, but it differs in having the declivital striae and interstriae very obscurely punctured; the tuberculate frontal carina of female robai is absent; and the declivity is much more shallowly excavated than in coffeae.

Female.- Length $2.0-2.3 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown, elytra slightly lighter.

Frons transversely, concavely impressed at level of ocular emargination, convex above; epistomal callus broad but poorly developed, bearing one transverse row of setae; upper area subreticulate, a few punctures and setae in lateral areas; lateral margins below fundus of impression acute.

Pronotum 1.06 times as long as wide; sides straight and parallel on more than basal half, broadly rounded in front; anterolateral angles armed by a row of about seven small, basally contiguous asperities; median line narrowly, rather acutely elevated over basal two-thirds; surface coarsely, shallowly punctured, most punctures longitudinally confluent; vestiture short, coarse, conspicuous, covering entire surface.

Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; sides straight and parallel to base of declivity, rather broadly rounded behind; basal margins acutely elevated, crenulations poorly defined; striae impressed, punctures small, largely confluent toward suture, discernible; interstriae twice as wide as striae, setiferous punctures small, in rows, mostly finely granulate. Declivity steep, convex except flattened or weakly impressed between third interstriae; striae 1 narrowly impressed, others weakly, rather indefinitely impressed; interstriae 1 weakly elevated, all with a row of fine, subgranulate, setiferous punctures, surface subreticulate, subshining. Vestiture of long, erect, stout, interstrial bristles from base to apex, and finer, recumbent, rather long strial and interstrial setae; bristles about as long as distance between bristles within a row and between rows.

Male. - Similar to female except epistomal callus broad, higher, its upper slope ornamented by a broad, dense brush of erect, rather long, reddish hair, slightly less extensive than in coffeae; elytral declivity a little less coarsely punctured.

Distribution.- Costa Rica.
COSTA R1CA: San Ignacio de Acosta, San José, 5-V11$63,1000 \mathrm{~m}$, No. 27, 28, tree twigs, S. L. Wood.

Brology. - This species was taken from pith tunnels in twigs $3-5 \mathrm{~mm}$ in diameter. As nearly as could be determined, a larva
completed its development on a volume of pith about two to three times that of its own body. It was not possible to distinguish the parental tunnel from the areas enlarged by the larvae.

Notes. - The above treatment was based on the type series of 34 specimens. Comparisons to robai were based on myhomotypes; those to coffeae were based on specimens bearing data identical to that of the type and agreeing in all details to the original description and to notes sent by Schedl comparing perplexus to the type of coffeae.

## 26. Cnesinus atavus Wood

Cnesinus atarus Wood, 1968, Great Basin Nat. 28:106 (Holotype, male; Rinconada, Veracruz, Mexico: Wood Coll.)
Diagnosis. - Although not at all closely related, this species is more nearly allied to annectens Wood than to other known forms. It is easily distinguished by the presence of an epistomal callus in both sexes and ornamented in the male by numerous specialized bristles, by the less extensive frontal impression, by the more coarsely strigose pronotum, and by other characters mentioned in the above key.

Female.- Length 2.2-2.4 mm, 2.4 times as long as wide; color dark brown.

Frons transversely impressed at level of ocular emargination, convex above, flattened below that level; epistomal callus rather high, transversely, rather broadly carinate on slightly more than median half, ornamented by coarse hair in an indefinite patch; surface of convex area to just above upper level of eyes minutely, transversely etched, granulate above; vestiture, in addition to that in impressed area, confined to sides, not conspicuous; eyes rather widely separated.
Pronotum 0.97 times as long as wide, widest just in front of middle, sides feebly arcuate on basal half, rather broadly rounded in front; surface shining, coarsely, longitudinally strigose, grooves somewhat irregular but punctures not indicated. Vestiture short, fine, mostly abraded in central area, coarser and more conspicuous on margins.
Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds to base of declivity, somewhat narrowly rounded behind; basal
margins armed by rather well developed, overlapping crenulations, an indefinite row of smaller, submarginal crenulations also present; striae impressed, small punctures indicated but largely confluent; interstriae almost twice as wide as striae, closely marked by small, confused, subgranulate punctures. Declivity moderately steep, convex, except very shallowly impressed between third interstriae; striae impressed, perhaps wider than on disc, punctures obscure; interstriae rather narrowly convex on upper half, convexity greatly reduced below, surface irregular, subgranulate. Vestiture abundant, stout, short, with median interstrial rows of erect, slightly longer bristles, each bristle a little shorter than distance between rows.

Male.-Similar to female except epistomal callus narrowly carinate, slightly higher, its upper slope ornamented by a large patch of long, reddish, specialized bristles.

Distribution. - Veracruz.
MEXICO: Veracruz: 3 km S Rinconada, 6-VII-67, 270 m . No. 170, large ( 2 m ), dead, herbaceous plant characterized by a strong, distinctive order, by S. L. Wood.

Biology. - Specimens were taken from pith tunnels in the smaller stems. The habits evidently are similar to most other species in the genus.
Notes. - The above treatment was based on the type series of 22 specimens.

## 27. Cnesinus annectens Wood

Cnesinus annectens Wood, 1967, Great Basin Nat. 27:86 (Holotype, female; Zamorano, Morazán, Honduras; Wood Coll.)
Diagnosis.- The absence of anatomical specialization makes characterization of this species difficult. Biologically it is unique; it is the only representative of the Bothrosternini that constructs biramous egg tunnels in the cambium region of the host in the usual hylesinine fashion (see below). According to Schedl (pers. comm.), it is allied to guadeloupensis Eggers; however, declivital interstriae 2 is not narrowed or eliminated before the apex as in guadeloupensis.

Female. - Length 1.9-2.5 mm, 2.2 times as long as wide; color brown with white vestiture.

Frons broadly impressed, almost concave, from upper level of eyes to epistoma, an obscure epistomal callus indicated; surface reticulate, obscurely below, coarsely above, with
small indefinite punctures rather uniformly, not closely spaced; vestiture rather widely distributed, consisting of fine, long, yellow hair, much longer above; distance between eyes equal to twice greatest width of an eye.

Pronotum 0.93 times as long as wide; very slightly wider at base, sides very feebly arcuate on about basal two-thirds, broadly rounded in front; surface coarsely, not deeply punctured, punctures evidently reticulate, almost all longitudinally confluent, very narrow, irregular interspaces smooth, shining; median line narrow, weakly raised from anterior fourth to base. Vestiture short, abundant, fine except almost scalelike near all margins.

Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds to declivital base, rather broadly rounded behind; basal crenulations small, distinct; striae rather shallowly impressed, punctures moderately large, deep; interstriae about twice as wide as striae, convex, punctures small, numerous, subgranulate, in three obscure ranks. Declivity rather steep, laterally convex, impressed between third interstriae; striae and strial punctures impressed, not reduced; interstriae as wide as striae, with granules slightly larger than on disc, uniseriate, 1 and 2 continuing to apex, 3 obscured on lower third. Vestiture abundant, erect, consisting of stout interstrial bristles, median row on each interstriae a third longer than ground cover, but shorter than distance between rows.

Male.-Similar to female except frontal impression shorter, not as deep, frontal vestiture much shorter, some setae on upper frons three-fourths as long as distance between eyes.

Distribution.- Honduras.
honduras: Zamorano, Morazán, 18-1V-64, 700 m , No. 566, Verbisina agriculorum, S. L. Wood.

Brology.- Just above the ground level in the green base of dying plants up to 4 cm in diameter, or up to a meter above the ground in larger, almost green host plants, the transverse, biramous parental tunnel was cut about half in the xylem and half in the phloem tissues. The tunnels were broad, somewhat cavelike, primitively biramous excavations with three to eight egg niches placed along one or more sides. The eggs were mixed with frass and packed in the
niches. The larvae fed more or less communally in the phloem tissues, scarcely engraving the wood, until approximately the end of the second instar. By this time the female parent had cut a tunnel from the egg chamber to the pith at the central axis of the stem. All third instar larvae present were in the pith tunnels. Larvae older than the third instar were not present in the sample studied. After cutting the tumnel into the pith the parent adults appeared to abandon the tunnels, evidently to begin a second brood.

Notes. - The above treatment was based on the type series of 118 specimens.

## 28. Cnesinus costulatus Blandford Figs. 84, 87

Cnesinus costulatus Blandford. 1896, Biol. Centr. Amer., Coleopt. 4(6):137 (Lectotype, female; Volcán de Chiriquí, Chiriquí, Panama; British Mus. Nat. Hist., present designation)
Cnesinus similis Blackman, 1943, Proc. U.S. Nat. Mus. 94:375 (Holotype, female; Panama; U.S. Nat. Mus.); Wood, 1971, Great Basin Nat. 31:144. Synonymy
Diagnosis.- The sulcate, bicarinate discal interstriae of this species and of porcatus Blandford, coupled with the long, transverse frontal carina in the female, distinguish these two species from all others in the Central American fauna. However, this species and porcatus are almost indistinguishable except for size and the female frons. Some individuals are distinguished with ease by characters mentioned by Blandford and in the above key, but in the series at hand every character breaks down on at least some specimens, except size (see diagnosis of porcatus below).

Female. - Length $2.0-2.3 \mathrm{~mm}$ (Mexican series $2.2-2.7 \mathrm{~mm}$ ), 2.24 times as long as wide; color black.
Frons transversely divided by an acute, high carina at level of ocular emargination, carina slightly longer than narrowest distance between eyes, a semicircular, smooth, shining area with a few minute points extending from carina to upper level of eyes, reticulategranulate above and laterally; area below carina rather strongly impressed, flattened, subshining, closely, rather finely punctured; vestiture fine, rather sparse, shiny area above carina glabrous; eyes rather widely separated.

Pronotum 0.93 times as long as wide; widest just behind middle, sides weakly

Fig. 87. Cncsinus spp.: 18, costulatus; 19, porcatus; 20, squamosus: 21, frontalis; 22, prominulus (not minax); 23, adustus (not atrodeclivis); 24, strigicollis; 25, minitropis; 26, setulosus (not ocularis). (After Wood 1968:97.)
arcuate on posterior two-thirds, almost parallel, broadly rounded in front; surface coarsely, longitudinally strigose, ridges slender, shining, impressions wider, rather dull, punctures obsolete. Vestiture consisting of fine, sparse, long hair.

Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel to base of declivity, rather narrowly rounded behind, declivity occupying posterior third; basal margins acutely elevated in a continuous costa, crenulations not indicated; striae abruptly, rather deeply impressed, shining, punctures largely confluent but clearly indicated except on 1 , rather large; interstriae as wide as striae, margins narrowly elevated, shining, median half sulcate, dull, punctures very fine, obscure. Declivity rather steep, convex; striae about as on disc; interstriae narrower, convex, with a single, median costa on upper third of each interstriae, costa broken into a series of small, subserrate granules below. Vestiture of very fine, hairlike setae on disc, somewhat coarser and more abundant on declivity; consisting of interstrial rows of very closely set, erect setae about as long as distance between rows, and sparse, finer, shorter, strial and interstrial hair.

Male.-Similar to female except frontal carina absent, upper area uniformly reticulate, lower area less strongly impressed.

Distribution.- Oaxaca to Colombia.
MEXICO: Oaxaca: 24 km S Valle Nacional, 20-V-71, 1300 m, D. E. Bright. COSTA RICA: Pandora, Limón, 23-VIII-63, 50 m , No. 141, dead tree seedling, No. 149, broken tree branch; Volcán, Puntarenas, 11-XII-6.3, 1000 m. No. 304, broken tree branch; San Ignacio de Acosta, San José, 5-VII-63, 1600 m , No. 37, woody vine; all by S. L. Wood. PANAMA: Bugaba and Volcán de Chiriquí, Chiriqui, G. C. Champion. OTHER COUNTRIES: Colombia.

Hosts.- At least two tree species and a woody vine.

Biology.- Essentially as in most of the preceding species of this genus.

Notes.- Two series of my Costa Rica specimens were compared directly to the remaining six of Blandford's original nine syntypic specimens now in the British Museum (Natural History). Blandford's first syntype, a female from Volcán de Chiriquí, is here designated as the lectotype of the species. In addition to the type series 43 other specimens were used to prepare the above treatment.

## 29. Cnesinus porcatus Blandford

Fig. 87
Cnesinus porcatus Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6):137 (Lectotype, female; Cerro Zu nil, Volcán de Chiriquí. Panama; British Mus. Nat. Hist., present designation)
Diagnosis.- Distinguishing features as in the above diagnosis of costulatus Blandford. In addition, the lower area on the female frons is more strongly impressed, with the vestiture usually more abundant and longer; above the carina the frons is uniformly reticulate (in costulatus the transition from the smooth, shining area to the dull, reticulate area is abrupt.)

Female.- Length $2.8-3.1 \mathrm{~mm}, 2.30$ times as long as wide; color black.

Frons uniformly reticulate above carina, with minute punctures; below carina broadly, concavely impressed, lateral margins partly acute, otherwise as in costulatus. Pronotum and elytra as in costulatus.

Male.-As in male of costulatus except lower frons more broadly, deeply impressed, punctures smaller, obscure.

Distribution.-Guatemala to Venezuela.
GUatemala: Cerro Zumil, Quezaltenango, G. C. Champion; Volcán de Agua, Esquintla, 19-V-64, 1000 m , No. 619, cut woody vine, S. L. Wood. COSTA RICA: Escasu, San José, 2-X-63, 1.300 m , No. 218 cut seedling, No. 219, Orcopanax capitatus; San Pedro de Monte de Oca, San José, 88-17978, R. Mendez. PANAMA: Volcán de Chiriquí, Chiriquí. G. C. Champion, and 11-I-64. 1800 m . No. 388 Quercus twig, No. 414 dead tree seedling, S. L. Wood. VENEZUELA: Exact locality not recorded, Moritz.

Hosts.- Oreopanax capitatus, Quercus sp., two other tree species, and a woody vine.

Notes. - The six syntypic specimens in the British Museum (Natural History) were compared directly to my Panama and Guatemala specimens. Since a type for this species has never been designated, I here designate a female from Volcán de Chiriquí as the lectotype of the species. The lectotype, 2 lectoparatypes, and 37 other specimens were used to prepare the above treatment.

## 30. Cnesinus squamosus Wood Fig. 87

Cnesinus squamosus Wood, 1968, Great Basin Nat. 28:102 (Holotype, female; Lower Río Tempisque, Guanacaste, Costa Rica; Wood ColI.)
Diagnosis.- This unique species is the most aberrant in the genus known to me. The
broad, scalelike ground vestiture, the strongly produced, suturally emarginate elytral spices, and the rather strongly elevated elytral interstriae 1,5 , and 9 distinguish it from all others.
Female.- Length $1.7-2.1 \mathrm{~mm}, 2.5$ times as long as wide; color brown.

Frons with a very low, crescent-shaped, transverse carina at level halfway between antennal bases and upper margins of eyes, convex above and moderately impressed below this carina; tufts of rather long, close, erect, reddish hair above epistomal area and at sides below carina largely obscure surface; surface granulose above, with a few short, recumbent, yellow scalelike and hairlike setae above carina; eyes separated by more than 2.5 times width of an eye; scape with a tuft of long, yellow hair.

Pronotum 1.0 times as long as wide; sides straight and parallel on basal two-thirds, rather abruptly narrowed then broadly rounded in front; surface coarsely, deeply, closely punctured, with rim of puncture of side opposite summit slightly elevated; vestiture abundant, covering entire surface, consisting of short scales, each about three or four times as long as wide, stouter posteriorly.
Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides straight and parallel to declivital base, posterior profile extended into a broad, emarginate process about half as long as wide; basal crenulations low, distinct; striae impressed, punctures moderately large, mostly obscured by confluence; interstriae slightly less than twice as wide as striae, surface obscured by vestiture but evidently rather coarsely, closely punctured, at least median row partly granulate. Declivity rather steep, ending below horizontal apical extension; interstriae 1,2 , and 5 reaching apex, 1 moderately, 5 strongly elevated, 3,4 , 6,7 , and 8 somewhat convex and ending near middle ( 3 ends in 5 in some specimens), 1 slightly elevated but ending at base of flange before attaining costal margin; costal margin raised from base of declivity to junction with rather strongly elevated 5 , angulately, shallowly emarginate to suture; crests of interstriae evidently finely serrate, obscured by vestiture. Vestiture consisting of interstrial scales of two types; first, median rows of
erect bristles on each interstriae about five or six times as long as wide, slightly shorter than distances between bristles between rows and within rows; second, broad scales, half as long as bristles, arranged with about one row on each side of row of bristles, anteriorly each scale slightly longer than wide, posteriorly each slightly wider than long; declivital interstriae 2 with one row of scales, no bristles.

Male.-Similar to female except frontal carina and tufts of reddish hair absent; frontal impression greatly reduced; tuft of hair on scape reduced; elytral sculpture evidently coarser.

Distribution.- Costa Rica, Panama, and Venezuela.

COSTA RICA: Near mouth of Río Tempisque, Guanacaste, 25-111-64, 15 m, No. 503, cut woody vine, S . L. Wood. PANAMA: Paraíso, Canal Zone, 5-IIl-11 and 11-V-11, E. A. Schwarz. OTHER COUNTRIES: Venezuela.

Host. - Serjania spp.
Biology.- The specimens were taken from the central axis of stems less than 5 mm in diameter. The habits are similar to those of most other species in the genus.

Notes.- The above treatment was based on the type series of 14 specimens and on 242 other specimens from Venezuela.

## 31. Cnesinus frontalis Wood <br> Fig. 87

Cnesinus frontalis Wood, 1968, Great Basin Nat. 28:104 (Holotype, female; Puerto Viejo, Heredia, Costa Rica; Wood Coll.)
Diagnosis.- This species is unique among known species in having the female carina much longer, more nearly angulate, and higher laterally but lower medially than in other species; both sexes lack specialized frontal vestiture. Other relationships are noted in the above key.

Female.- Length $2.0-2.3 \mathrm{~mm}, 2.4$ times as long as wide; color almost black.

Frons rather shallowly impressed at level of ocular emargination, convex above, below with a very strongly elevated, subangulate carina occupying median two-thirds, its lateral angles highest; short area below carina somewhat flattened, with median area distinctly raised; surface above carina reticulate; vestiture sparse, inconspicuous.

Pronotum 1.1 times as long as wide; sides straight on basal two-thirds, very slightly wider in front of middle, rather broadly rounded in front; surface rather coarsely, rather deeply punctured, each puncture about twice as long as wide, many confluent; vestiture hairlike, inconspicuous except in front and at sides.

Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; sides straight and parallel to declivital base, rather broadly rounded behind; bases slightly elevated, crenulations not indicated except for submarginal, coarse punctures; striae very weakly impressed, punctures rather large, moderately deep, close, completely confluent on posterior third of disc; interstriae about twice as wide as striae, almost flat, punctures fine, deep, abundant, confused. Declivity steep, convex, somewhat flattened in median area; striae 1 slightly impressed, others not impressed, punctures small, deep; interstriae 1 slightly elevated, 3 very slightly convex, all armed by rows of rather large, rounded granules. Vestiture largely restricted to declivity, consisting of moderately long, interstrial rows of bristles and short, more abundant, similar bristles, longer ones about equal in length to distance between rows.

Male.-Similar to female except frontal carina absent, a broad, transverse, epistomal callus present with a scanty brush of erect hair on its upper margin; a pair of small rounded calluses in frontal impression.

Distribution.- Costa Rica.
COSTA RICA: Puerto Viejo, Heredia, 12-IIl-64, 70 m , No. 479, woody vine; Peralta, Cartago, IO-1II-64, about 70 m , No. 463 , wood vine; all by S. L. Wood.

Biology.- Evidently similar to most other species in the genus.
Notes.- The above treatment was based on the type series of 37 specimens.

## 32. Cnesinus denotatus Wood

Cnesinus denotatus Wood, 1968. Great Basin Nat.
28:107 (Holotype, female; Barro Colorado 1sland, Canal Zone, Panama; Wood Coll.)
Diagnosis. - This species is allied to frontalis Wood, but it is easily distinguished by the smaller size, by the mroe finely punctured pronotum, and by the much narrower, higher female frontal carina.

Female.- Length $1.8-1.9 \mathrm{~mm}, 2.4$ times as long as wide; color dark reddish brown.

Frons rather strongly impressed at level of ocular emargination, convex above, flattened below this level, with a very strongly elevated, transverse carina at level of antennal insertion, its transverse length equal to about one-fourth distance between eyes, almost as high as wide; surface minutely reticulategranulate; vestiture reduced, short, largely confined to lateral areas.

Pronotum 1.07 times as long as wide; sides straight and almost parallel on basal twothirds, very slightly wider in front of middle, rather broadly rounded in front; surface shining, very closely, rather finely punctured, punctures slightly longer than wide, mostly longitudinally confluent. Vestiture mostly on marginal areas, short, stout.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds to declivital base, then rather narrowly rounded behind; crenulations on basal margins indistinct, marked by rather large, submarginal punctures; striae impressed, punctures moderately large, partly confluent; interstriae wider than striae, subshining, punctures fine, abundant, confused. Declivity moderately steep, convex except impressed between third interstriae; striae 1 moderately, others not impressed; interstriae 1 feebly elevated, 2 weakly impressed, 3 higher but feebly convex, each with a row of setiferous granules. Ground vestiture rather abundant, stout, hairlike on disc, scalelike and almost as wide as long on declivity; rows of interstrial bristles erect, each bristle stout, very slightly longer than distance between bristles within a row or between rows.

Male.-Similar to female except frontal carina absent, a weak, shining, epistomal callus present; declivital bristles very slightly flattened.

Distribution.- Costa Rica, Panama, and Venezuela.

COSTA RICA: Santa Ana, San José, 4-X-63, 1000 m , No. 219. Oreopanax capitatus, S. L. Wood. PANAMA: Barro Colorado Island, Canal Zone, 27-XII-63, 70 m , No. 341, blacklight, S. L. Wood.

Biology. - The allotype was taken from the central axis of a twig 5 mm in diameter. The habits evidently are similar to most other species in the genus.

Notes.- The above treatment of this species was based on the type series of two specimens and on one other specimen.
33. Cnesinus minax Schedl

Cnesinus minax Schedl, 1952, Dusenia 3:352 (Holotype. female; Mexico; Schedl Coll.)
Diagnosis.- This species is distinguished from prominulus Wood by the stouter body, by the smaller size, by the less abundant, longer vestiture, by the color, and by other minor details.

Female.- Length $2.5 \mathrm{~mm}, 2.5$ times as long as wide; color brown.

As in prominulus except as noted in the above diagnosis.

Distribution.- Veracruz.
MEXICO: Veracruz: Motzorongo.
Notes. - The above treatment was based on the holotype labeled "Mexico, Flohr," and on two specimens in the British Museum (Natural History) from Motzorongo, Veracruz, reported by Blandford (1896:139) as strigicollis. The pins, mounting cards, glue, and condition of the specimens strongly suggest that all three specimens came originally from the same series.

## 34. Cnesinus prominulus Wood

 Fig. 87Cnesinus prominulus Wood, 1977, Great Basin Nat. 37:212 (Holotype, female; Volcán Colima, Jalisco, Mexico; Wood Coll.)
Diagnosis.- This species is allied to adustus Schedl but is distinguished by characters mentioned in the above key and in the diagnosis of that species.

Female.- Length $2.7-3.3 \mathrm{~mm}$ (males $2.4-3.1 \mathrm{~mm}$ ), 2.7 times as long as wide; color dark brown, pronotum somewhat reddish.

Frons shallowly impressed at level of antennal bases, flattened and with acute lateral margins below, weakly convex above that point; transverse frontal carina at level of ocular emargination moderately high, short, about equal in width to one-fourth distance between eyes; median third above carina transversely etched, glabrous, lateral areas obscurely punctured, bearing rather abundant, long, course, yellow hair; epistomal callus absent, brush of reddish, ornamental bristles well developed.

Pronotum 1.07 time as long as wide; sides feebly arcuate, almost straight, from base to widest point two-thirds length from base, broadly rounded in front; surface longitudinally strigose, ridges irregularly sinuate, as
wide as grooves, punctures of grooves entirely obsolete; median line narrowly elevated on more than basal half. Vestiture consisting of short, stout setae on entire surface, longer anteriorly.

Elytra 1.6 times as long as wide, 1.9 times as long as pronotum; sides almost straight and parallel on more than basal two-thirds to declivital base, rather narrowly rounded behind; basal crenulations low, distinct on median half, a few submarginal crenulations on interstriae 2-4; striae impressed, punctures small, shallow, separated by distances equal to their own diameters, interstriae about twice as wide as striae, subshining, confused setiferous punctures granulate. Declivity steep, convex except shallowly impressed between third interstriae; striae 1 impressed, others not impressed except above; interstriae 1 slightly elevated, 2 weakly impressed, 3 broadly convex, 3 armed by a row of fine granules. Vestiture abundant on disc and declivity, very slightly longer on declivity; consisting of rows of stout, erect, interstrial bristles, each bristle slightly shorter than distances between bristles within a row or between rows, and shorter, more abundant ground vestiture of fine to stout strial and interstrial setae, each seta up to two-thirds length of a bristle.

Male.-Similar to female except frontal carina absent, impression more extensive, shallowly concave, deepest at level of ocular emargination, epistomal callus weakly indicated, its brush of ornamental bristles reduced to about one row of yellowish bristles.

Distribution.-Jalisco.
MEXICO: Jalisco: Volcán Colima, 23-VI-65, 2500 m , No. 107, twigs of shrub, S. L. Wood.

Biology.- My series was taken from pith tunnels in small twigs. Evidently the habits are similar to most other species in the genus.

Notes. - The above treatment was based on the type series of 32 specimens, on my homotype that was compared directly to the female holotype; and on 30 other specimens bearing identical data.
35. Cnesinus adustus Schedl

Fig. 87
Cnesinus adustus Schedl, 1949, Rev. Brasil Biol. 9:266 (Holotype, female: Turrialba, Costa Rica; Schedl Coll.)

Cnesinus atrodeclivis Wood, I968, Great Basin Nat. 28:108 (Holotype, female; Zamorano, Morazán, Honduras; Wood Coll.); Wood, 197.4, Great Basin Nat. 34:279. Synonymy
Diagnosis.- This species is allied to minax Schedl, but it may be distinguished by the smaller size, by the coarser, shorter vestiture, by the more strongly impressed declivital striae, and by the more extensively flattened female frons.

Female.- Length 2.0-2.3 mm, 2.5 times as long as wide; color dark reddish brown, declivity much darker.

Frons transversely impressed at level of antennal insertion, flattened above this level to upper level of eyes, except weakly transversely convex between eyes; armed at level of ocular emargination by a minute, crescentshaped, transverse carina; transverse length of carina about equal to one-sixth distance between eyes; epistomal callus weakly developed, its upper slope ornamented by a rather large patch of reddish ornamental bristles; surface rather coarsely reticulate on median third, broad lateral areas above carina ornamented by rather numerous, very long, stout, yellow hair.

Pronotum 1.06 times as long as wide; shape, sculpture, and vestiture as in denotatus (above) except surface more nearly strigose, punctures virtually obsolete.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds to declivital base, rather narrowly rounded behind; basal crenulations very low, poorly formed, interstriae 2-4 bearing several submarginal, indistinct crenulations; striae impressed, punctures moderately large, most confluent on 1 and 2; interstriae wider than striae, punctures fine, numerous, confused, subgranulate. Declivity steep, convex except slightly flattened toward suture; striae impressed, punctures not reduced, largely confluent; interstriae convex, each with a median row of setiferous punctures. Vestiture rather abundant, stout; ground vestiture more than half as long as rows of interstrial bristles on disc; ground vestiture and bristles merge on declivity to form closly set, almost uniseriate rows of short bristles.

Male.- Similar to female except frontal impression extending to level of ocular emargination, convex above this level, impressed
area subconcave; frontal carina absent, its ornamental bristles reduced to a single, transverse row.

## Distribution.- Honduras.

honduras: Zamorano, Morazán, I8-IV-64, 700 m , No. 548, Valeriana scandens, S. L. Wood.

Biology.- All specimens were taken from pith tunnels in the central axis of stems less than 3 mm in diameter. Habits evidently are similar to most other species in the genus.

Notes.- The above treatment was based on the holotype of adustus and on the type series of seven specimens of atrodeclivis.

## 36. Cnesinus pilatus Wood

Cnesinus pilatus Wood, 1975, Great Basin Nat. 35:24 (Holotype, female; 13 km W El Palmito, Sinaloa, Mexico; Canadian Nat. Coll.)
Diagnosis. - This species is distinguished from strigicollis LeConte by the larger size, by the stouter body form, by the different female frons, by the absence of tubercles on declivital interstriae 2, and by other characters noted below.

Female.- Length $3.1 \mathrm{~mm}, 2.1$ times as long as wide; color dark brown, elytra dark reddish brown.

Frons as in strigicollis except area below carina slightly less strongly impressed, distance between eyes 0.8 times as wide as width at level of antennal insertion (as in strigicollis), carina 0.5 times as wide as distance between eyes, median impunctate area above carina larger, extending above upper level of eyes, vestiture in lateral areas not extending above upper level of eyes and not on me dian third at vertex (extending well above eyes and almost to median line in strigicollis).

Pronotum 0.9 times as long as wide; about as in strigicollis except more closely, slightly more coarsely strigose.
Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; similar to strigicollis except interstriae three times as wide as striae, declivity more broadly impressed, declivital interstriae 2 devoid of granules, vestiture about half as long, stouter, interstriae 2 on declivity with a row of punctures, each puncture about two-thirds as large as those of adjacent striae.

Distribution.- Sinaloa.
MEXICO: Sinaloa: 13 km W El Palmito, 7 -VIII-64, H. F. Howden.

Notes.- The above treatment was based on the holotype.

## 37. Cnesinus strigicollis LeConte Fig. 87

Cnesinus strigicollis LeConte, 1868, Trans. Amer. Ent. Soc. 2:171 (Lectotype, female; lllinois; Mus. Comp. Zool.. 976, present designation)
Nemophilus strigillatus Chapuis, 1869, Synopsis des Scolytides, p. 27 (Syntypes; Amerique boreale, Texas; Brussels Mus.); LeConte, 1876, Proc. Amer. Philos. Soc. 15:378. Synonymy
Diagnosis.- This species is distinguished from carinatus Wood by the smaller size, by the more narrowly separated eyes, by the coarser elytral vestiture, by the distribution and, in the female, by the shorter frons, the longer carina, and the much more strongly convex area above the carina.

Female.- Length 2.2-2.7 mm, 2.5 times as long as wide; color dark reddish brown.

Frons strongly, transversely impressed immediately below level of ocular emargination, then abruptly elevated to transversely elevated, slightly procurved carina, convex above carina, impressed and flattened below; epistomal margin finely, weakly elevated, epistomal callus almost absent, impressed area bearing a rather large patch of reddish, ornamental bristles; median third of area above carina transversely etched, glabrous, lateral areas obscurely punctured, bearing numerous long, coarse, yellow setae; area above eyes finely granulate; eyes separated by 1.8 times width of an eye.

Pronotum 1.0 times as long as wide; widest near middle, sides weakly arcuate, almost parallel on basal two-thirds, broadly rounded in front; surface longitudinally, rather coarsely strigose, ridges shining, about equal in width to dull grooves, punctures obsolete. Vestiture short, fine, hairlike, longer and stouter in marginal areas.

Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds to declivital base, rather narrowly rounded behind; crenulations on basal margins low, distinct, overlapping, an indefinite row of submarginal crenulations on interstriae 2-6; striae impressed, punctures rather large, shallow, almost obsolete on 1 and 2 ; interstriae wider than striae, punctures small, confused, about a third of
them subcrenulate. Declivity moderately steep; convex except shallowly impressed between third interstriae; striae 1 impressed; others impressed on upper half only; interstriae 1 moderately elevated, 2 weakly impressed, 3 convex, 3 and upper part of 2 each bearing a row of small, rounded granules. Vestiture rather abundant, moderately coarse; consisting of recumbent, rather abundant ground vestiture and interstrial rows of erect, slightly longer, somewhat coarser bristles; bristles on declivity as long as distance between rows, spaced slightly closer within row, slightly shorter on dise.

Male.-Similar to female except frontal carina absent, convex area almost flat; epistomal callus more conspicuous, ornamental bristles reduced to one transverse row of coarse, yellow hair; frontal surface coarsely reticulate.

Distribution.- Michigan and New York to Texas, Florida, and Chiapas.
USA: District of Columbia: Washington. Florida: Alachua Co., Capps, Gainesville, Highlands Hammock St. Pk., Jacksonville, Key Largo, Miami, Plantation Key. Georgia: Savannah. Louisiana: Bell Chase. Maryland: Bladensburg, Washington Co. Michigan: Grand Ledge. Missouri: "Missouri." New Jersey: Newark, Westville. New York: Flushing (Long Island), Staten Island, Orange Mts. North Carolina: Myrtle Beach, Tryon. Ohio: Cincinnati, Delaware Co., Westerville. Pennsylvania: Mit. Alto. South Carolina: Dorchester, Florence, Myrtle Beach. Tennessee: "Tenn." Texas: Columbus, Victoria. Virginia: Cape Henry, Lake Drummond. Ft. Monroe, Rosslyn. West Virginia: Monongalia Co., Upshur Co. MEXICO: Chiapas: Junction of Highways 190 and 195, Chiapa del Corzo.

Hosts.- Amerimonon brownei, Ardesia paniculata, Bumelia lanuginosa, Carya spp., Coccolobis laurifolia, Dipholis salicifolia, Fagus grandifolia, Liquidambar styraciflua, Magnolia glauca, Pyrus communis, Quercus sp., Smiliax sp., Toxoxylon pomifcrum.

Biology.-Schwarz (1891:79) observed a female of this species in a Sweet Gum branch 30 mm in diameter. A female cut a tunnel through the bark and about 6 mm into the wood, where the tunnel turned to continue an undulating course parallel to the grain of wood to a total length of 17 mm , ending 5 mm from the outer surface. This species ordinarily selects twigs or other woody stems considerably smaller than that observed by Schwarz, and the tunnels normally reach the central axis of the stem. All the stems I have seen attacked by this species were less than

10 mm in diameter. The larvae extend the parental tunnel and evidently always emerge through the original entrance hole.

Notes. - The above treatment was based on two LeConte syntypes and on 294 other specimens. Consistent geographical variation was not apparent.

Blandford reported this species from Motzorongo, Veracruz, Mexico, in error. The Flohr specimens he reported actually are of minax Schedl. Of the two syntypes on which LeConte based his species, 1 here designate the first, a female, as the lectotype of strigicollis. Two specimens from Chiapas (Mexico) in the Canadian National Collection may be of this species. The female has the specialized bristles on the lower frons in a uniseriate, transverse row and the lateral setae above the carina are longer. More material is needed to determine the significance of these deviations.

## 38. Cnesinus carinatus Wood

Cnesinus carinatus Wood, 1967, Great Basin Nat. 27:85
(Holotype, female: Ciudad Hidalgo, Michoacán. Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from minax Schedl by the great reduction of pronotal and elytral vestiture, by the much more strongly impressed elytral declivity, by the smaller size, and, in the female, by the slightly wider frontal carina, with the frons more strongly impressed below the carina and less strongly impressed above.

Female. - Length $2.5-3.1 \mathrm{~mm}, 2.7$ times as long as wide; color brown.

Frons with a transverse carina at level of ocular emargination, eyes separated by 2.6 times its transverse length, rather weakly convex above carina, rather strongly impressed, flattened below this point; surface above and below carina reticulate, finely punctured and pubescent; vestiture above yellow, moderately long, abundant, shorter in median area, below carina reddish, erect, arranged in a narrow, transverse brush not reaching epistomal margin; eyes separated by a distance equal to 2.3 times greatest width of an eye.

Pronotum 1.09 times as long as wide; sides almost straight on basal two-thirds, very slightly wider in front of middle; surface rather coarsely, longitudinally strigose to
base; punctures almost entirely obsolete; vestiture confined to marginal areas.

Elytra 1.8 times as long as wide, 2.0 times as long as pronotum; sides almost straight and parallel to base of declivity, rather broadly rounded behind; basal crenulations low, distinct, with a few small submarginal crenulations on interstriae $2-5$; striae impressed, punctures small, impressed; interstriae about twice as wide as striae, convex, surface somewhat irregular, punctures fine, confused, median row evidently subgranulate. Declivity steep, rather strongly impressed between third interstriae as in flavopilosus; striae 1 moderately impressed, others not impressed, punctured reduced; interstriae 1 convex, moderately elevated, 2 impressed, elevated laterally, elevation continuing to moderately high summit on 3 , each interstriae with a row of fine granules, granules very feeble except on 3. Vestiture hairlike, those on median row of each interstriae longer and stouter, particularly on declivital interstriae 3 and laterally; bristles on declivital interstriae 1 and 2 not longer than on disc, some of those on 3 twice as long.

Male.-Similar to female except frontal carina absent; frons concavely impressed on lower two-thirds of area below upper level of eyes, entire frons pubescent, but setae longer and more abundant at sides and along smaller epistomal brush.

Distribution.-Michoacán.
MEXICO: Michoacán: 6 km west Ciudad Hidalgo, 16-V11-53, 2000 m , No. 107, in twigs of a small rosaceous tree somewhat resembling apple, S. L. Wood.

Biology.- Young adults were removed from pith tumnels along the central axis of stems less than 1 cm in diameter. Evidently the habits are similar to most other species in the genus.

Notes.- All 16 specimens in the type series were examined during this study.

## 39. Cnesinus setulosus Blandford Figs. 84,87

Cnesinus setulosus Blandford, 1896, Biol. Centr. Amer.. Coleopt. $4(6): 139$ (Lectotype, male; Tolé, Chiriqui', Panama: British Mus. Nat. Hist., present designation)
Cnesinus flacopilosus Schedl, 1940, An. Esc. Vac. Cienc. Biol., Mexico 1:333 (Holotype, male?; Comitán, Mexico: Schedl Coll.); Wood, 1972, Great Basin Nat. 32:144. Synonymy

Cnesinus panamensis Blackman. 1943, Proc. U.S. Nat. Mus. 94:372 (Holotype, male, Panama; U.S. Nat. Mus., 56549); Wood, 1972, Great Basin Nat. 32:144. Synonymy
Cnesimus cognatus Blackman, 1943, Proc. U.S. Nat. Mus. 94:373 (Holotype, female; El Petén Province, Guatemala; U.S. Nat. Mus., 56550); Wood. 1971. Great Basin Nat. 31:144. Synonymy
Diagnosis.- This species is closely related to adusticus Wood, but may be distinguished by characters summarized in the above key. The spacing between the eyes may be highly variable between and within series.

Female. - Length $1.8-2.5 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown, vestiture almost white.

Frons with a slightly procurved, transverse carina at level of ocular emargination, its length equal to 1.7 times distance between eyes, weakly convex and coarsely reticulate above carina, transversely, rather strongly impressed and flattened below; epistomal callus very obscure, its upper margin marked by one transverse row of reddish, ornamental bristles; other vestiture confined to lateral areas from just below level of carina to upper level of eye, coarse, abundant, rather long; eyes separated by $0.6-1.6$ times width of an eye (variable within and between series).

Pronotum 1.1 times as long as wide, very slightly wider anteriorly, sides almost straight and parallel on basal two-thirds, rather broadly rounded in front, coarsely, longitudinally strigose, most furrows rather short, subreticulate, ridges shining, mostly narrower than grooves, punctures obscurely evident (variable). Vestiture short, covering entire surface, very fine on disc, stout on all margins.

Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds to declivital base, rather narrowly rounded behind; crenulations on basal margins distinct, with smaller submarginal crenulations on interstriae 2-4; striae impressed, punctures incrasingly confluent toward suture; interstriae slightly wider than striae, punctures rather coarse, close, confused, their anterior margins very slightly elevated but not granulate. Declivity steep, convex except shallowly impressed between third interstriae; striae less strongly impressed, punctures clearly but not sharply impressed; interstriae l very feebly elevated,

2 weakly impressed, 3 slightly elevated, narrowly convex, setiferous punctures uniseriate on $1-3$. Vestiture consisting of rows of rather short, stout, interstrial bristles, each not longer than distance between rows, usually not evident on basal half of disc, and slightly shorter, semirecumebnt, more abundant, interstrial ground vestiture, each seta at least as wide as bristles (except very slightly narrower in one Honduras series).

Male.-Similar to female except frontal carina absent, transverse row of ornamental bristles yellowish. less strongly modified.

Distribution.-Colima and Tamaulipas to Panama

MEXICO: Chapuis: 49 km W Lazardo Cardenes. $25-$ VI-69, Camphell and Bright. Colima: $3 \mathrm{~km} W$ Armeria, 28-VI-65, 70 m , No. 152, tree twigs, S. L. Wood. Oaxaca: 157 km N Oaxaca, 18-V-71, at light, D. E. Bright; 116 km S Oaxaca on Highway 131, 11-V-71, 2200 m, Arbutus, D. E. Bright. Tamaulipas: Victoria, 22-V-52, M . Cazier. GUATEMALA: El Petén Province, 8 -IV-22, H. F. Loomis; Palin, Esquintla, 19- V-64, 350 m, No. 591, Cola de Pavo twigs, S. L. Wood. HONDURAS: Olanchito, Yoro, 7, 30-VII-49, at light, E. C. Becker: San Lucas, Paraíso, 22-IV-64. 800 m , Scriania mexicana, S. L. Wood; Zamorano, Morazan, 18-IV-64, 700 m , No. 546, Acacia pennatula twigs, S. L. Wood. PANAMA: Ancón, Canal Zone, IV-11, Kraft; "Panama."

Hosts.- Acacia pennatula, Seriania mexicana, etc.

Biology.- Specimens were taken from axial pith tunnels in small twigs or vines. The habits appeared to be as in other species of the genus.

Notes.- During this study 53 examples of this species were examined, including the lectotype of setulosus and the holotypes of panamensis and cognatus. A male and female from my Palin series were compared by Schedl to the type of flavopilosus. The above descriptions were prepared from a female homotype of cognatus from Olanchito, Honduras, a male homotype of panamensis from Ancon, Panama, and the male lectotype from Tolé, Panama, and a male lectoparatype from San Lorenzo, Panama, of setulosus.

From Blandford's series of three male syntypes, the first, from Tolé, Chiqiruí, Panama, has been considered the type for practical reasons. This male is here designated as the lectotype of Cnesinus setulosus Blandford.

This is a highly variable species; no two series were exactly alike. The eyes of Mexican and some Honduras specimens were
more narrowly separated and the declivital ground vestiture was more nearly scalelike. The Panama specimens tended to have the eyes more widely placed and the pronotum less strongly strigose, with most punctures clearly isolated. Specimens from intermediate localities usually exhibited intermediate characters, but each series was slightly different. Considerably more material from the area south of Guatemala must be examined before geographical races or other variant forms can be characterized. It is possible that flavopilosus represents a subspecies.

## 40. Cnesinus minitropis Wood

$$
\text { Fig. } 87
$$

Cnesinus minitropis Wood, 1968, Great Basin Nat. 28:105 (Holotype, female; San Ignacio de Acosta, San José, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from minax Schedl by the more closely placed eyes, by the finer pronotal and elytral vestiture, by the longer lateral bristles on the elytral declivity, by the presence of a transverse band of dark scales at the base of the elytral declivity, by the slightly wider impression on the elytral declivity, and, in the female, by the slightly smaller frontal carina.

Female. - Length $3.0-3.2 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown, elytra slightly lighter, vestiture almost white except for a narrow transverse band of dark setae across elytral base.

Frons flattened on lower half, convex above, a short, transverse, procurved carina occupying less than median third; epistoma ornamented by a dense brush of long, suberect, reddish bristles; surface of upper area minutely, transversely etched, punctured above upper level of eyes; vestiture limited to epistomal brush and sides above, setae in lateral areas very long, coarse, rather abundant near eyes; eyes separated by less than 1.1 times width of an eye, by 2.4 times width of frontal carina.

Pronotum 1.03 times as long as wide; sides almost straight on basal two-thirds, widest in front of middle, rather broadly rounded in front; surface rather coarsely, longitudinally strigose, narrow, impunctate median line slightly elevated; vestiture mostly of fine, short, inconspicuous hair, with some scalelike setae at base and on anterior third.

Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; sides straight and parallel on basal two-thirds to base of declivity, rather broadly rounded behind; basal crenulations distinct, low, a few submarginal crenulations on interstriae 2-5; striae impressed, punctures partly confluent, usually distinct; interstriae about twice as wide as striae, weakly convex, surface irregular, punctures fine, abundant, confused, mostly subgranulate. Daclivity steep, convex except weakly impressed between third interstriae; striae 1 slightly impressed; interstriae 1 slightly elevated, punctures rather small, deep; interstriae with median rows of small, setiferous rounded granules. Vestiture consisting of interstrial rows of erect, stout bristles, bristles on dise separated within rows and between rows by distances equal to length of a bristle, slightly longer in lateral areas on declivity; ground vestiture more abundant, consisting of narrow scales about half as long as bristles, each scale about four times as long as wide, largely eliminated on declivity.

Male.-Similar to female except frontal area concavely impressed over broad area, vestiture very slightly shorter.

Distribution.-Costa Rica.
COSTA RICA: San Ignacio de Acosta, San José, 5 -VII63, 1000 m , twigs of a cultivated tree, S. L. Wood.

Host- - A cultivated tree, probably Annona sp .

Biology. - The specimens were taken from pith tunnels in small twigs. Evidently the habits are similar to those of most other species in the genus.

Notes.- The above treatment was based on the six specimens in the type series.

## 41. Cnesinus adusticus Wood

Cnesinus adusticus Wood, 1967, Great Basin Nat. 27:87
(Holutype, female; Los Amendros, Paraíso, Honduras; Wood Coll.)
Diagnosis.- This species is allied to setulosus Blandford and minitropis Wood, but it may be distinguished by characters summarized in the above key.

Female. - Length $2.6-3.3 \mathrm{~mm}, 2.4$ times as long as wide; color reddish brown, with white and cinereous vestiture.

Frons with an arcuate, sharply elevated, transverse carina at level of ocular emargination occupying median one-third to one-half;
weakly convex above, flattened below carina; most of lower area covered by a brush of erect reddish bristles; upper area minutely, transversely strigose in central area, punctured and granulose at sides and above; lateral areas above carina and below upper level of eyes bearing rather abundant, long, erect, plumose, yellow setae; eyes separated by a distance equal to $1.0-1.6$ times the greatest width of eye.
Pronotum 1.05 times as long as wide; widest in front of middle, sides weakly arcuate, strongly rounded anteriorly, then rather broadly rounded in front; surface longitudinally rather coarsely strigose, most punctures confluent; vestiture scanty except in marginal areas, partly almost scalelike at base and near anterior margin.

Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; crenulations on elytral bases not well developed; striae impressed, punctures rather large, very close; interstriae about one and one-half times as wide as striae, surface irregular, punctures confused, some median ones partly granulate. Declivity moderately steep, impressed between third interstriae; striae not impressed, punctures rather large, deep; interstriae 1 rather weakly elevated, 2 impressed, essentially flat, 3 and evidently part of lateral area forming a rather abrupt, moderately high crest, lateral interstriae ending in this rounded summit, declining and obsolete before apex; each interstriae bearing a row of small setiferous granules. Vestiture fine, almost hairlike on anterior two-thirds of disc, becoming coarse and scalelike behind; consisting of rather abundant, short, interstrial setae and rows of longer, erect setae, none as long as distance between rows.

Male.-Similar to female except frontal carina absent, upper area more strongly convex, reticulate, lower area more broadly flattened; epistomal brush somewhat reduced, yellow.

## Distribution.- Honduras to Colombia.

honduras: Los Amendros, Paraíso (near Zamorano), 18-IV-64, 700 m , No. 546, Acacia pennatula, S. L. Wood. COSTA RICA: San José, San José, 22-X-63, 1300 m, No. 172, woody vine, S. L. Wood. OTHER COUNTRIES: Finca El Bosque, Caicedonia, Valles, Colombia, 20-Vl-59, coffee, J. Restrepo.

Hosts.- Acacia pennatula, Coffea arabica, and a woody vine.

Habits.- Specimens were taken from twigs and small branches $5-40 \mathrm{~mm}$ in diameter. The pith tunnels indicated habits similar to those of most other species in the genus.

Notes. - The above treatment was based on the holotype, allotype, 37 paratypes, and 13 additional specimens. See the above taxonomic notes under setulosus for possible confusion involving this species.

Genus PAGIOCERUS Eichhoff

Pagiocerus Eichhoff, 1868, Berliner Ent. Zeitschr. 12:148 Type-species: Pagiocerus rimosus Eichhoff $=$ Bostrichus frontalis Fabricius, subsequent designation, by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:126)
Diagnosis.- This genus is distinguished from other Central American Bothrosternini by the procurved antennal sutures, by the rounded lateral margins of the prothorax, by the stout body form, by the distinctive frons, and by the seed-boring habit.

Description.- Length $1.9-2.6 \mathrm{~mm}, 1.9$ times as long as wide; sexes almost identical; front moderately excavated on lower twothirds, with lateral margins acute and a large, median, epistomal tubercle, subglabrous. Eyes sinuate, finely granulate; widely separated. Antennal funicle 7 -segmented; club slender, 1.8 times as long as wide, basal half marked by two moderately procurved sutures, suture 3 entirely obsolete. Pronotum moderately constricted anteriorly, surface punctured, unarmed. Scutellum small, round. Crenulations on elytra obscure, very poorly developed, basal margins slightly elevated; striae impressed, punctures mostly distinct; interstriae irregular, punctured, unarmed. Declivity convex, moderately steep. Vestiture hairlike; short, mostly in interstrial rows on declivity.

Distribution. - Southeastern United States to Argentina; occasionally intercepted in South American shipments of corn to other parts of the world. Five species are known, only one occurs north of South America.

Biology. - The adult beetle, presumably the female, bores into the large seeds of various trees or other plants, notably Zea mays,
where she is joined by a male and the brood is reared.

Pagiocerus frontalis (Fabricius) Fig. 88

Bostrichus frontalis Fabricius, 1801, Systema Eleutheratorum 2:389 (Syntypes; Carolina; Copenhagen Mus.)
Pagiocerus frontalis: Eggers, 1929. Wiener Ent. Ziet. 46:42
Pagiocerus rimosus Eichhoff, 1868, Berliner Ent. Zeitschr. 12:148 (Syntypes?; Cuba; evidently destroyed in the Hamburg Mus.); Schedl, 1960. Coleopt. Bull. 14:6. Synonymy
Bothrostermus hubbardi Schwarz, 1886, Ent. Americana 2:54 (Holotype, sex?; St. Lucie, Florida; U.S. Nat. Mus.); Anderson, 1948, Proc. Ent. Soc. Washington 50:215. Synonymy
Hylastinus fiorii Eggers, 1908, Ent. Blätt. 4:215 (Holotype, sex?; Cenoa, Italy; Andr. Fiori Coll., Bologna).
Pagiocerus fiorii: Eggers, 1940, Ent. Blätt. 36:62; Schedl, 1960, Coleopt. Bull. 14:6. Synonymy
Pagioferus zeae Eggers, 1928, Archiv. Inst. Biol. 1:92 (Syntypes); Eggers, 1940, Ent. Blätt. 36:62 (Syynonymy): Schedl, 1960, Coleopt. Bull. 14:6 (Synonymy): Anderson and Anderson, 1971, Smithsonian Contrib. Zool. 94:36 (Lectotype, sex?; South American corn kernels; U.S. Nat. Mus. 60312)
Pagiocertu chiriquensis Eggers, 1928, Archiv. Inst. Biol. 1:92 (Holotype, sex?; Volcán, Chiriquí, Chiriquí, Panama; not in U.S. Nat. Mus., apparently on loan to Schedl); Schedl, 1960, Coleopt. Bull. 14:6. Synonymy
Pagiocerus nitidus Eggers, 1931, Ent. Blätt. 26:170 (Holotype, sex?? Caracas, Venezuela; Berlin Zool. Mus.); Schedl, 1960. Coleopt. Bull. 14:6. Synonymy
Pagiocerus caraibicus Eggers, 1940, Arb. Morph. Tax. Ent. Berlin-Dahlem 7:136 (Holotype, sex?; Trios Rivières, Guadeloupe, not in U.S. Nat. Mus., apparently on loan to Schedl); Schedl, 1960. Coleopt. Bull. 14:6. Synonymy
Diagnosis.- This is the only representative of the genus known to occur outside of South America. The stout body, the bifid process on the anterior tibiae, the procurved antennal sutures, the distinctive frons, and other characters mentioned in the above generic key distinguish it from other North and Central American species.

Female.- Length 1.9-2.6 mm, 1.9 times as long as wide; color very dark brown.
Frons impressed from upper level of eyes to just above epistoma, rather strongly concave on lower two-thirds of this area; lateral margins of deeply impressed area acutely elevated and slightly produced to form an indistinct tubercle at level of antennal
insertion; epistomal margin armed by a rather large, median, pointed (usually) tubercle; impressed area at level of ocular emargination bearing a pair of small calluses and an obscure, median fovea immediately above them; surface smooth below, subreticulate above, with moderately abundant, fine punctures on all marginal areas; vestiture sparse, short, obscure except in marginal areas. Eyes separated by 2.2 times width of an eye.

Pronotum 0.97 times as long as wide; sides widest about one-third length from bisinuate basal margin, rather strongly arcuate then abruptly convergent to moderate constriction just behind narrowly rounded anterior margin; surface smooth and shining, with close, coarse, partly longitudinally confluent punctures, substrigose. Vestiture minute; usually abraded on disc.
Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; slightly wider at base of declivity, sides almost straight, rather broadly rounded behind; basal margins weakly elevated, crenulations feebly indicated; striae impressed, punctures indicated, often largely confluent on 1 and 2; interstriae broadly convex, as wide or wider than striae, punctures moderately coarse, close, confused, surface irregular, shining. Declivity beginning near middle of elytra, convex, moderately steep; sculpture much as on dise except interstriae narrower and interstrial punctures uniseriate. Vestiture consisting of rows of short, close, interstrial bristles, each about two-thirds as long on declivity as distance between rows.

Male.- Similar to female except abdominal tergum 8 not concealed by 7 as in female. Distribution.- North Carolina and Texas to Argentina.

USA: Florida: Amelia Isl., 13-VIII-06, Nighthawk stomach; Brevard Co., 3-1-30, trap, J. Howard; Gainesville, 5-I-39, Nos. 8311, 8359, J. R. Watson; Little River, 2-1X-18, Ocotea catesbiana; Miami, 1-X-06, Persea borbonia fruit, G. S. Fawcett; Satsuma Heights, Hopk. US 6732. Georgia: Savannah, 26-XII-34, P. borbonia seed. North Carolina: Specimens seen, data not recorded. South Carolina: Folly Beach, 4-1X-44, Persea fruit. Texas: Weslaco, 12-X-55, P. americana fruit, Williamsen and Allen. MEXICO. Distrito Federal: Mexico, 1-V1145, P. americana seed. Mexico: Chapingo, IV-61, Persea, K. C. Padilla. Nayarit: 8 km S Santiago Ferry. Puebla: 24 km E Teziutlan, 5-6-VIII-60, H. F. Howden. GUATEMALA: At light in banana hold, I1-V-36. EL SALVADOR: San Andrea, 20-25-V11-44, E. V. Hambleton. COSTA RICA: Cativo seed pod, 15-VII-35; "Tucurrique," Schedl and Burgdorf. PANAMA: La Campana,

X-37, Trap, Zetek; Canal Zone, numerous records from light, one record from corn seed.

Hosts.- Ocotea sp., Persea spp., and Zea mays.

Biology.- This species infests large seeds of various trees and other plants. It has commonly been reported from corn seed, where it has caused substantial economic loss in South America. The habits are known to me only from secondary sources.

Notes. - The above treatment was based on a female from Tingo María, Peru, and a male from Pasto, Colombia, that had been compared to (1) the type series of hubbardi, (2) the type of chiriquensis, (3) the type of zeae, and (4) a specimen identified as frontalis by Schedl, and on 353 other specimens.

## Genus BOTHROSTERNUS Eichhoff

Bothrosternus Eichhoff, 1868, Berliner Ent. Zeitschr. 12:150 (Type-species: Bothrosternus truncatus Eichhoff, monobasic)
Diagnosis.- This genus and Sternobothrus differ from other representatives of the Bothrosternini by the acute lateral margins of the pronotum coupled with straight, transverse sutures of the antennal club. It differs from Sternobothrus by the excavated and densely pubescent proepisternal area, by the transverse, subcarinate ridge between the anterior
coxae, and by the ambrosial habit; the elytral interstriae may be carinate.

Description.- Length 1.9-3.1 mm, 1.9-2.2 times as long as wide; color very dark brown to black; presumably partly parthenogenetic, males very rare or unknown; frons convex above, flattened below, carinate in species treated here. Eyes sinuate on anterior margin, finely granulate; widely separated. Antennal funicle 7 -segmented; club slender, with two straight, transverse sutures. Pronotum unarmed, surface punctured to substrigose. Basal crenulations of elytra very poorly developed; striae impressed, punctures obscure; interstriae simple, unarmed, sometimes becoming carinate posteriorly. Declivity convex, rather steep. Vestiture of hairlike setae, becoming uniseriately bristlelike on declivity.

Distribution.- Southern Mexico to southern Brazil. Ten species have been assigned to this genus, two of which occur in Mexico and Central America.

Biology.- The two species treated here construct pith tunnels in the central axis of small woody vines or twigs of various trees, where they cultivate a loose, fluffy fungus that is used for food by the brood and evidently also by the adults. The larvae do not extend the parental gallery.

## Key to the Species of Bothrosternus

1. Frons with a large, conspicuous, median longitudinal carina; elytral interstriae flat on disc, weakly arched on declivity; Veracruz to Costa Rica; $1.9-2.3 \mathrm{~mm} . .$.

> 1. foveatus (Blackman)

- Frons with a transverse carina at level of antennal insertion in female, absent in male; elytral interstriae narrowly carinate posteriorly on disc and on declivity; Costa Rica to Panama; 2.9-3.1 mm

2. definitus Wood
3. Bothrosternus foveatus (Blackman) Fig. 84

Cnesinus foveatus Blackman, 1943, Proc. U.S. Nat. Mus. $94: 375$ (Holotype, female; Trece Aguas, Alta Verapaz, Guatemala; U.S. Nat. Mus., 56553)
Bothrosternus foveatus: Wood, 1968, Great Basin Nat. 28:110
Diagnosis. - This is the only species in the genus known to me having a median frontal carina and a small proepisternal excavation.

Female.- Length $1.9-2.3 \mathrm{~mm}, 2.2$ times as long as wide; color very dark brown to black.

Frons convex on upper half, transversely impressed below, somewhat flattened; a con-
spicuous median carina extending from just below level of ocular emargination to well above upper level of eyes; a pair of small, sublateral calluses at level of antennal insertion; epistomal margin slightly elevated; surface dull, reticulate, with a few minute granules; vestiture sparse; inconspicuous.

Pronotum 0.98 times as long as wide; widest at middle, sides almost straight and diverging on basal third, then strongly arcuate to slight constriction just behind rather broadly rounded anterior margin; basal margin bisinuate; surface closely, rather coarsely punctured, about one and one-half to two
times as long as wide; surface inside punctures reticulate, dull, interspaces almost smooth, shining; subglabrous.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; sides almost straight and subparallel on basal three-fourths to just behind level of declivital base, then broadly rounded behind; basal margin feebly elevated, crenulations scarcely indicated; striae abruptly, not deeply impressed, punctures indicated largely confluent; interstriae about twice as wide as striae, reticulate, dull, punctures fine, rather abundant, confused. Declivity convex, steep; striae more deeply impressed; interstriae narrower, as wide as striae, each with a uniseriate row of minute granules, reticulate. Vestiture largely confined to declivity, consisting of rows of interstrial bristles confused toward base, each bristle not longer than distance between rows.

Male.- Not recognizable in material at hand.

Distribution.- Veracruz to Costa Rica.
MEXICO: Veracruz: 1 km N Cerro Gordo, 29-VI-53, 1000 m , No. 61 and 6-VII-67, No. 166, Seriania sp. Oaxaca: 30 km N Matías Romero, 24 -VI- $67,150 \mathrm{~m}$, No. 97, S. L. Wood. GUATEMALA: Trece Aguas, Alta Verapaz, $300 \mathrm{~m}, \mathrm{H}$. G. Barber and E. A. Schwarz. EL SALVADOR: Tonocatepeque, 20-VI-58, L. S. Bottimer. COSTA RICA: Finca gromaco on Río Coto Brus, Puntarenas, 14 -VII- $63,500 \mathrm{~m}$, Nos. 63, 67, woody vine; Santa Ana, San José, 1-VIII-63, No. 92, Cupania guatemalensis, 4-X-63, No. 219, Oreopanax capitatus, and 8-XI-63, No. 255, broken twig.

Hosts.- Cupania guatemalensis, Oreopanax capitatus, Serjania sp., and an unidentified tree.

Habits.- Specimens were collected in moist areas of $500-1300 \mathrm{~m}$ elevation from tunnels in the central axis of twigs and woody vines less than 1 cm in diameter. A fluffy white fungal mycelium was in each tunnel and apparently served as the principal, if not the only food of the larvae. From the entrance hole the tunnel extended directly inward to the pith, where it branched to follow the central axis in each direction for $2-3 \mathrm{~cm}$. Evidently the larvae did not extend the parental tunnel but fed only upon the ambrosial fungus until the prepupal stage. Individual pupation chambers were then formed by partitioning off sections of the tunnel with plugs of mycelium and frass. The age distribution in these cells was not regular; the oldest
young adult or pupa was not always nearest the entrance tunnel. Only one parent adult occurred in each gallery; males could not be recognized among the specimens collected.

Notes.- The above treatment was based on the holotype and on 69 other pinned specimens and more than 200 specimens preserved in alcohol.

## 2. Bothrosternus definitus Wood

 Fig. 88Bothrosternus definitus Wood, 1968, Great Basin Nat. 28:109 (Holotype, female; Finca Gromaco on Río Coto Bus, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.-Similar to a specimen from Peru tentatively identified as cancellatus Chapuis, but distinguished by the more coarsely, shallowly, substrigosely punctured pronotum and by the very different sculpture of the frons.

Female.- Length 2.95-3.05 mm, 1.9 times as long a wide; color black.

Frons convex above antennal bases, flattened and transversely impressed below, with a fine, sharply raised transverse carina occupying median three-fourths at level of antennal bases; closely punctured and finely, closely pubescent from carina to epistomal margin and on area of similar size above carina; median two-thirds from pubescent area to vertex polished, marked only by minutely etched transverse lines; sides and above rugose-reticulate with shallow, indefinite punctures and short, sparse hair.

Pronotum 1.8 times as long as wide; widest behind middle, sides very strongly arcuate and strongly constricted before anterior margin, basal margin bisinuate and extending into scutellar notch; surface dull, closely, shallowly, coarsely punctured, punctures elliptically elongate, some twice as long as wide; glabrous.

Elytra 1.2 times as long as wide; sides almost straight and parallel on slightly more than basal half, rather broadly rounded behind; striae strongly, rather abruptly impressed, punctures almost obsolete; interstriae wider than striae on disc, moderately convex on basal half, becoming narrowly carinate behind and on declivity, punctures on basal half of disc small, shallow, confused, obscure. Declivity rather steep, convex; interstriae very narrowly carinate on upper
third, becoming finely beaded below; striae rugose-reticulate, punctures obscure, much wider than interstriae.

Male.-Similar to female except frontal carina absent; frons with a short, transversely impressed, median, elevated summit halfway between level of antennal insertion and ocular emargination.
Distribution.- Costa Rica.
COSTA RICA: Peralta, Cartago, 10-III-64, 500 m , No. 461, woody vine; Finca Gromaco on Río Coto Brus, Puntarenas, 14-VII-63, 500 m , No. 63, woody vine; all taken by S. L. Wood. Panama: "Panama."
Hosts. - Two very different species of woody vine.

Biology.- The habits appear to be very similar to those of foveatus, except that the mature larvae, pupae, and young adults were always arranged in their pupal cells with the most nearly mature nearest the parental entrance tunnel. They decreased in age or maturity regularly as the distance from the entrance hole increased. A loose, fluffy, white, fungal mycelium was conspicuous in all but the newest galleries. The males were rare among the brood; they did not occur in any tunnel with a female parent except as a matured representative of her brood.

Notes.- The above treatment was based on a study of the 55 female and three male specimens that comprise the type series.

## Genus EUPAGIOCERUS Blandford

Eupagiocerus Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6):133 (Type-species: Eupagiocerus
dentipes Blandford, monobasic); Wood, 1965, Great Basin Nat. 25:31 (Revision)
Nemopagiocerus Schedl, 1962, Mitt. Münchner Ent. Ges. 52:85 (Type species: Eupagiocerus nevermannii Schedl = Eupagiocerus ater Eggers, monobasic); Wood, 1965, Great Basin Nat. 25:31. Synonymy
Diagnosis.- From other Central American Bothrosternini this genus is distinguished by the sharply elevated lateral margins of the pronotum, and by the procurved sutures of the antennal club.

Description.- Length $2.1-3.8 \mathrm{~mm}$, 1.8-2.3 times as long as wide; frons convex above, flattened to shallowly concave below and often ornamented by setae and sculpture, sexually dimorphic. Eyes weakly sinuate, finely granulate; widely separated. Antennal funicle 7 -segmented, club rather slender to moderately stout, with two procurved sutures on basal half. Pronotum punctured to substrigose; unarmed. Scutellum small, round. Elytral bases weakly elevated, marked either by a continuous costa or by feebly developed crenulations; striae impressed, punctures often obsolete; interstriae variable. Declivity convex, steep; armed by moderately large tubercles in one species.

Distribution.-Guatemala to Venezuela and Peru. Four species.

Biology. - The adult female constructs a tunnel in the pith at the central axis of stems of small woody vines, where she is joined by the male. The larvae enlarge the parent gallery, pupate, and emerge through the original entrance hole. One species, ater, cultures a fungus in its tunnels on which the larvae feed.

## Key to the Species of Eupagiocerus

1. Sutures 1 and 2 of antennal club moderately procurved, with 2 not extending beyond basal third of club; declivital interstriae equally convex, each bearing a single row of rounded tubercles; declivital vestiture stout, almost scalelike; frons modified in both sexes; Costa Rica; $3.0-3.8 \mathrm{~mm}$ $\qquad$ 1. vastus Wood

- $\quad$ Sutures 1 and 2 of antennal club strongly procurved, with 2 extending at least to middle of club; declivital interstriae 2 impressed or at least less strongly elevated than either 1 or 3 and, except at upper margin, devoid of tubercles
2(1). Larger, discal interstriae moderately convex, not ending abruptly, posteriorly; declivital interstriae 2 and perhaps lower part of 3 somewhat impressed or flat and devoid of tubercles; declivital tubercles small, rounded; Chiapas to Panama; 2.6-3.0 mm upper margin of declivity, each elevation ending posteriorly as a small, sharply pointed spine, a row of similar pointed tubercles continuing down each declivital interstriae (except 2); Costa Rica to Venezuela and Peru; 2.1-2.6 mm

3. ater Eggers

## 1. Eupagiocerus vastus Wood Fig. 88

Eupagiocerus vastus Wood, 1965, Great Basin Nat. 25:34 (Holotype, female; Puerto Viejo, Heredia, Costa Rica; Wood Coll.)
Diagnosis.- This species is very closely related to dentipes Blandford but may be distinguished by the characters summarized in the above key.

Female.- Length $3.0-3.8 \mathrm{~mm}, 2.1$ times as long as wide; color rather dark brown.

Frons shallowly concave on lower half, feebly convex above, with median third remarkably sculptured; lower half with lateral margins acute and slightly elevated, a narrow marginal and epistomal area irregularly punctured, this area marked dorsally by a deep, narrow, procurved, transverse groove and immediately above this a transversely elevated, low, median carina on median third; remaining area of lower half densely pilose; above groove and elevation a median, subhexagonal, impunctate area densely, very closely reticulate-granulate, a shallow transverse groove near lower margin of hexagonal area and immediately above rounded carina; lateral pubescence and median hexagonal area extended to upper level of eyes; dorsal areas of head subreticulate and finely, shallowly punctured. Antennal club narrowly ovate, 1.4 times as long as funicle; suture 1 broadly procurved, extending one-fifth club length from base, 2 narrowly subangulate, extending two-fifths club length from base.

Pronotum 0.9 times as long as wide; base bisinuate, sides on basal half straight to distinctly constricted, diverging anteriorly, then abruptly narrowed to a constriction just before very broadly rounded, subemarginate, anterior margin; surface dull, rather closely marked by moderately large, elongate punctures, each puncture about twice as long as wide, their size slightly smaller anteriorly and laterally; lateral margins acute on basal
two-thirds, pleural areas rather coarsely punctured; glabrous.

Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal half, rather narrowly rounded behind; basal margins bisinuate, slightly elevated, not at all crenulate or carinate; striae very feebly impressed anteriorly on disc, somewhat more strongly impressed toward declivity, punctures indicated but very feebly impressed; interstriae more than twice as wide as striae, almost flat anteriorly, weakly convex at base of declivity, surface dull, densely, microscopically reticulate (at 80 diameters) and also finely, closely, confusedly punctured, about four to six punctures across width of an interstriae. Declivity moderately sieep, convex, surface including striae closely reticulate-granulate, each interstriae bearing a median row of small but high, rounded granules, each granule as high as wide and spaced by distances about equal to distance between rows of granules. Vestiture consisting of rows of erect bristles, each arising from base of a granule, and forming a median row on each interstriae, each bristle almost as long as distance between rows; and irregular rows of shorter bristles about half as long as main rows, located on each side of median row. Interstriae 9 subacutely elevated.

Male.- Similar to female except frons subconcavely impressed on lower half and densely pilose in impressed area, special sculpturing absent.

Distribution. - Costa Rica.
COSTA RICA: Puerto Viejo, Heredia, I2-III-64, 50 m , No. 477, and Peralta, Cartago, 10-III-64, 50 m , No. 462 . S. L. Wood.

Host.- An unidentifiable woody vine (liana).

Biology.- Specimens were removed from pith tunnels in the ventral axis of stems $4-5$ cm in diameter. From the entrance tunnel,
which extended directly to the pith, the beetles constricted linear galleries along the central axis $2-4 \mathrm{~cm}$ in each direction. The larvae and young adults extended the parental tunnel. There was no evidence of fungal growth in the tunnels. The number of males was almost equal to that of the females.

Notes.- The above treatment was based on the type series of 53 specimens.

## 2. Eupagiocerus dentipes Blandford

 Figs. 21, 88Eupagiocerus dentipes Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):133 (Lectotype, male: El Tumbador, Guatemala; British Mus. Nat. Hist., present designation)
Eupagioccrus clarus Wood. 1965, Great Basin Nat. 25:33 (Río Viejo, Volcán Chiriquí, Panama: Wood Coll.): Wood, 1971, Great Basin Nat. 31:145. Synomymy
Diagnosis.- This species is allied to ater, but it is readily distinguished by the larger size, by the more slender body form, by the elytral characters indicated in the above key, and by other features of the frons and prothorax.

Female.- Length 2.6-3.0 mm, 2.3 times as long as wide; body color black.

Frons broadly, evenly convex above and broadly, shallowly concave below level of ocular emargination, abrupt, pseudocarinate line of separateion between these areas extended orad slightly in median area; upper area reticulate, dull below, subshining above; lower areas shallowly, evenly concave between subacute lateral margins to epistomal margin; epistomal margin slightly raised, shining, with a small bilobed process; concave area rather densely, minutely pilose; other vestiture inconspicuous. Antennal club 1.8 times as long as wide, sutures procurved, 1 extending to a point one-third club length from base, 2 extending three-fifths club length from base.

Pronotum 1.1 times as wide as long, sides almost straight on basal half, slightly wider near middle, then abruptly narrowed to the broadly rounded anterior margin; surface closely, finely, longitudinally strigose over entire dorsal surface; subshining; glabrous.

Fig. 88. Bothrosternini genera and species, male heads: A, Pagiocerus frontalis; B, Bothrosternus definitus: C, Eupagiocerus vastus; D, Eupagiocerus dentipes; E, Eupagiocerus ater.

Hairlike setae in anterior pleural area longer and conspicuous, but not forming a definite tuft as in ater.

Elytra 1.4 times as long as wide, sides feebly curved, somewhat narrowly rounded behind; basal margins slightly elevated, neither crenulate nor acutely produced; striae narrowly, rather deeply impressed, punctures very obscurely indicated; interstriae feebly convex anteriorly, moderately so at base of declivity, about three times as wide as striae, surface reticulate, subshining, with numerous confused, small, shallow punctures. Declivity moderately steep, somewhat flattened between third interstriae; interstriae 1 slightly elevated, uniseriately punctured, with a few punctures bearing small, obscure, rounded granules, 2 flat, appearing impressed, with confused fine punctures, 3 and 4 convex on upper half and bearing regular rounded tubercles on convex portion, becoming flattened on lower half and merging into impression of 2,5 to 9 convex and each bearing a row of rounded tubercles. Vestiture scanty, restricted to a few hairlike setae in posterolateral areas.

Male. - Similar to female except frons with transition from convex to concave areas gradual, concavity slightly deeper, not pilose, but with a continuous tuftlike row of erect plumose setae on lateral and lower margins, concave area with rather numerous, small, hairlike setae.

Distribution.- Chiapas to Panama.
MEXICO: Chiapas: Palenque Ruins, 9-V-69, D. E. Bright. GUATEMALA: El Tumbador, G. C. Champion. PANAMA: Río Viejo at Volcán de Chiriquí, Chiriquí, 11-I-64, 1800 m , No. 412, vine, S. L. Wood.

Host.- A woody vine.
Habits. - The beetles were removed from pith tunnels in the central axis of a stem of a rough-barked woody vine 2 cm in diameter. There was no evidence of an ambrosial fungus; the larvae evidently enlarged the parental gallery as they do in most species of Cnesinus.

Notes.- The above treatment was based on the 34 specimens in the type series of clarus and the 3 males in the syntypic series of dentipes, all of which were examined in this study.

While I was studying at the British Museum a black female clarus was compared to
the teneral, reddish, male syntypes of dentipes. They differed not only in frontal sculpture, but in other features as well. Several years later, when teneral paratypes of clarus were compared to the syntypes, the synonymy was recognized. Because a type has not been designated from Blandford's series, I here designate the first specimen as the lectotype of dentipes Blandford.

## 3. Eupagiocerus ater Eggers

Fig. 88
Eupagiocerus ater Eggers, 1931, Ent. Blätt. 27:14 (Holotype, male; Caracas, Venezuela; Berlin Zool. Mus.).
Eupagiocerus nevermanni Schedl, 1952, Dusenia 3:350 (Holotype, female ?; Turrialba, Costa Rica; Schedl Coll.); Wood, 1965, Great Basin Nat. 25:32. Synonymy
Eupagiocerus serratus Wood, 1961, Great Basin Nat. 21:104 (Holotype, male; Paraíso, Canal Zone, Panama; U.S. Nat. Mus., 66509); Wood, 1965, Great Basin Nat. 25:32. Synonymy
Diagnosis.- This distinctive species is somewhat allied to dentipes, but it is easily distinguished by characters summarized in the above key.

Female.- Length 2.1-2.6 mm, 2.0 times as long as wide; color dark brown to black.

Frons above level of antennal bases convex, smooth and polished in central area, coarsely reticulate at sides and above; epistomal margin narrowly, weakly elevated, with a flattened, rugose-reticulate, sparsely punctured area immediately above; antennal bases connected by a broad, slightly procurved, rather high, acute, yellowish carina, subvertical on its lower side, moderately sloping, ornamentally punctured and pubescent on its supper slope; vestiture moderately abundant, longer and finer below, coarse and relatively short on upper slope of carina, a few setae along lateral margins above. Antennal club with suture 1 extending two-fifths and 2 two-thirds club length from base.

Pronotum 0.9 times as long as wide; widest at middle, sides almost straight, slightly diverging anteriorly on basal half, then rather strongly, arcuately rounded to broadly rounded anterior margin; surface subshining, with minute, rather obscure, longitudinal lines in interspacial areas, becoming reticulate laterally and basally, punctures elongate, rather coarse, close, shallow; glabrous.

Elytra 1.1 times as long as wide; sides straight and parallel on more than basal twothirds, very broadly rounded posterior profile interrupted by declivital serrations and sutural emargination; basal margins of elytra acutely elevated along a continuous costa; striae impressed, weakly on anterior third, very strongly toward declivital margin, punctures obsolete; interstriae about one and onehalf times as wide as striae at base, flattened basally, becoming strongly convex, almost as high as wide, toward declivity coarsely reticulate and somewhat irregular on basal third, punctures fine, confused, sparse on posterior half. Anterior half of pleural area from coxal flange to elevated margin of pronotum impressed, impression filled by dense yellow setae.

Declivity steep, flattened; surface granulose-reticulate over both punctures and serrations, strial punctures essentially obsolete, although position of some punctures indicated; sutural interstriae vertically, rather strongly elevated, declining in height on lower third, bearing about ten low, posteriorly directed serrations; interstriae 2 with a small, pointed serration at declivital base, weakly elevated below and sometimes bearing as many as four serrations, lower ones sometimes rounded: interstriae 4 to 9 each bearing about two to four rather coarse, posteriorly directed serrations. Vestiture consisting of a few short, fine to coarse setae on declivity.

Male.-Similar to female except frontal carina entirely absent and replaced by a broad, shallow impression; setae on antennal scape less numerous; and declivital sculpture evidently finer.

Distribution.- Costa Rica to Venezuela and Peru.

COSTA RICA: Peralta, Cartago, IO-III-64, 50 m , No. 463, woody vine, S. L. Wood: Turrialba, Cartago. 800 m . F. Nevermann; Monteverde, Puntarenas, 23-V-79, 140 $\mathrm{m}, \mathrm{H}$. and A. Howden. PANAMA: Ft. Clayton, Canal Zone, 22-III-63, 35 m . No. 319, Seriania, S. L. Wood; Paraiso, Canal Zone, 25-I-11, E. A. Schwarz. Specimens, also seen by me include the type from Caracas, Venezuela, and a cotype from Peru.

Hosts. - Seriania sp., and another woody vine.

Biology. - From the entrance hole in a stem $0.5-2.0 \mathrm{~cm}$ in diameter, axial tunnels in
the pith region may extend in either or both directions from 1 to 3 cm . On the walls of the older tunnels a thick, fluffy mat of fungus mycelium grew on which the larvae fed. The larvae apparently did not extent the parental mine. In galleries containing only eggs the mycelium was not visible.

Notes. - The above treatment was based on the type series of serratus (where the sexes were reversed), on the holotype of ater, on the type of nevermanni, and on 49 other specimens.

## Genus Sternobothrus Eggers

Sternobothrus Eggers, 1943, Mitt. Münchner Ent. Ges. 33:372 (Type-species: Bothrosternus canccllatus Chapuis, original designation)
Diagnosis. - This genus appears more closely allied to Cnesinus than to other genera in the Bothrosternini; however, the combination of characters employed in the above key places it nearest Bothrosternus. From Bothsternus it is distinguished by the absence of an excavation and dense pubescence on the proepisternal area, by the absence of a transverse carina between the anterior coxae, by the carinate elytral interstriae, and by the pith-feeding habit that does not involve an ambrosial fungus.

Description. - Length $\quad 2.2-3.6 \mathrm{~mm}$, 2.1-2.2 times as long as wide; color black; frons convex above, subconcavely impressed below and variously ornamented; sexually dimorphic. Eyes sinuate on anterior margin; finely granulate; widely separated. Antennal funicle 7 -segmented; club with two straight sutures on anterior face. Pronotum unarmed, surface punctured. Basal margins of elytra marked by an acutely elevated costa or by very indistinct crenulations; striae impressed, punctures obsolete; interstriae weakly convex and punctured toward base, acutely carinate on declvity. Declivity convex, moderately steep. Vestiture minute, sparse.

Distribution. - Costa Rica to Argentina. Nine species have been assigned to the genus; two of them occur in Central America.

Biology.- Both species construct pith tunnels in the central axis of small branches where the larvae extended the parental tunnel, essentially as they do in most species of Cnesinus.

## Key to the Species of Sternobothrus

1. Elytral apex neither explanate, emarginate, nor serrate; declivital interstriae 3 near apex distinctly elevated; Costa Rica to Brazil; 2.6-3.6 mm
2. sculpturatus (Blandford)

- Apices of elytra produced posteriorly into two short lobes, emarginate at suture, costal margins near suture finely serrate; declivital interstriae 3 not elevated; Panama to Venezuela, Brazil, and Peru; 2.0-2.5 mm

2. bicaudatus (Blandford)

## 1. Sternobothrus sculpturatus (Blandford)

Bothrostermus sculpturatus Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6):132 (Lectotype, female: Bugaba, Chiriquí, Panama; British Mus. Nat. Hist., present designation)
Sternobothrus sculpturatus: Eggers, 1943, Mitt. Münchner Ent. Ges. 33:373
Diagnosis. - Characters summarized in the above key serve to distinguish this species from bicaudatus (Blandford).

Female.- Length $2.6-3.6 \mathrm{~mm}, 2.0$ times as long as wide; mature color black.

Frons convex above level of ocular emargination, rather strongly, transversely, subconcavely impressed below, deepest just above level of antennal insertion; convex area finely punctured in marginal areas, central twothirds impunctate, minutely, transversely etched (smooth in a few specimens); impressed area bearing a median, submarginal, epistomal tubercle, its dorsal margin continuing dorsad as a low median carina in most specimens to lower margin of convex area; lower surface punctured, largely concealed by a rather dense brush of reddish bristles of equal length, tubercles glabrous; punctured portions of convex area bearing less abundant, yellowish hair to upper level of eyes.

Pronotum 0.95 times as long as wide; widest just behind middle, sides weakly arcuate on basal half, strongly arcuate in front of middle to moderate constriction just behind broadly rounded anterior margin; surface subshining, minutely reticulate, punctures on disc fine, deep, moderately close, at least twice as large and with reticulate centers near lateral margins; glabrous.

Elytra 1.3 times as long as wide; 1.5 times as long as pronotum; sides very faintly constricted at level of middle of disc, widest at base of declivity, then broadly rounded behind except profile interrupted by elevated interstriae 3; basal margins finely, almost
uniformly elevated on median half, a few small submarginal crenulations on interstriae 2-4; striae broadly impressed, punctures obsolete; interstriae rather broadly convex and obscurely punctured on basal third, becoming narrowly costiform before base of declivity and continuing to declivity; elytral surface coarsely reticulate except almost smooth and shining toward summits of costae. Declivity convex, rather steep, weakly impressed between third interstriae; striae and interstriae narrower than on disc; interstriae narrowly costiform, 3 very slightly higher, particularly as junction with 5 , this elevation continuing transversely after junction with 9 and diminishing in height to junction with 1 ; interstriae 4,6 , and 8 end short of junctions with adjacent costae. Vestiture obsolete except for rows of minute hair on either side of each declivital costa.

Male.- Evidently rare; one specimen presumed to be a male, similar to female except frontal exacavation slightly deeper and extending dorsad somewhat, vestiture greatly reduced, entirely yellowish.

## Distribution.- Costa Rica to S Brazil.

MEXICO: Oaxaca: 9 km S Valle Nacional, 18-V-71, 600 m , D. E. Bright. COSTA RICA: Guapiles, Limón, 14-1V-66, 50 m , No. 2: Pandora, Limón, 23-V111-63, 50 m, No. 149; Volcán, Puntarenas, 11-Xll-63, 1000 m , No. 304; all by S. L. Wood, from what appeared to be the same host tree species. PANAMA: Bugaba and Volcán de Chiriquí, Chiriquí, G. C. Champion.

Host.- A large tree, probably Nectandra sp.

Brology.- Pith tunnels were constructed in the central axis of cut or broken branches $2-5 \mathrm{~cm}$ in diameter, similar to those of most Cnesinus species. The larvae extended the parent tunnel and fed upon the host tissues.

Notes.- The above treatment was based on a female from the type series, on two of my homotypes, on 58 other Central American specimens, and on 158 South American
specimens. None of the material was as large as the 4 mm length reported by Blandford in the original description. The first female syntype in the Blandford series is here designated as the lectotype of sculpturatus.

## 2. Sternobothrus bicaudatus (Blandford)

Bothrosternus bicaudatus Blandford, 1896, Biol. Centr. Amer., Coleopt. $4(6): 133$ (Lectotype, Volcán de Chiriquí, Chiriquí, Panama; British Mus. Nat. Hist.)
Sternobothrus hicaudatus: Eggers. 1943. Mitt. Münchner, Ent. Ges. 33:373
Diagnosis. - This species is readily distinguished from the only other Central American representative of the genus by characters summarized in the above key.
Female.- Length $2.0-2.5 \mathrm{~mm}, 2.2$ times as long as wide; color almost black.

Frons convex above length of ocular emargination, impunctate, smooth and polished on central three-fourths, marginal areas punctured; lower area transversely impressed as in sculpturatus except tubercle and median elevation absent, epistomal process transversely carinate on more than median half, its upper slope to level of antennal insertion densely ornamented by rather long, reddish setae; lateral areas almost to upper level of eyes bearing shorter, rather sparse, yellowish setae.
Pronotum about 1.0 times as long as wide; outline as in sculpturatus; surface reticulate, punctures deep, rather coarse on disc, smaller laterally, rather close; glabrous.
Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; sides almost straight, very slightly wider at base of declivity, then
arcuately rounded to serrate, produced apices that occupy slightly more than median half, emarginate at suture; basal margins slightly elevated on a continuous costa; striae reticulate, impressed except at base, narrow on basal half, wider behind, punctures obsolete; interstriae feebly convex on basal half, rather narrowly convex at base of declivity, at least twice as wide as striae at elytral base, only slightly wider at base of declivity, punctures rather small, confused basally, tending to form uniseriate rows toward declivity on both margins of each interstriae except on 1 . Declivity convex, rather steep except lower fourth produced posteriorly; striae and interstriae narrower than on disc; interstriae narrowly costiform on upper fourth, becoming serrate below; suture emarginate, costal margin of produced area subserrate. Minute vestiture confined to declivity on summits of interstriae.

Male.-Similar to female except epistomal callus less well developed; ornamental epistomal setae reduced to one row, much shorter, color yellowish, central area of frons reticulate.
Distribution.- Panama.
PANAMA: Volcán de Chiriquí, Chiriquí, G. C. Champion.

Host.- Nectandra sp.
Habits. - Specimens of a very closely related species were taken from pith tunnels in twigs of a broken branch. Habits resemble those of most Cnesinus species.

Notes. - The above treatment was based on the syntypes of bicaudatus and on 22 other specimens.

## Tribe PHLOEOTRIBINi

Phloeotribidae Chapuis, 1869, Synopsis des Scolytides, p. 42 (Type-genus: Phloeotribus Latreille, 1796)
Phthorophloeides Nüsslin, 1912, Naturwiss. Zeitschr. Forst- und Landwirtschaft 1912:273 (Type-genus: Phthorophloeus Rey, 1883)

Anatomical features.- The frons is strongly, sexually dimorphic, with the male variously impressed, the female flat to convex; the eye is entire, the antennal funicle is 5 -segmented, the club is strongly asymmetrical and deeply divided into three movable, sublammelate segments, the procoxae are contiguous, the prosternum has the lateral margins rounded, its costa obsolete; the pronotum may or may not be armed by asperities, and the metatergum is fused to its postnotum.

Biological features.- All species are monogamous and phloeophagous. The parental tunnels are usually biramous, but when monoramous there is a conspicuous turning niche near the entrance tunnel. Larval mines follow a definite course away from the parental gallery and rarely cross one another. Symbiotic relationships with fungi have not been reported.

Taxonomy.- This tribe appears to be of American origin. One genus (Aricerus, Australia, etc.) appears to have reached its present distribution from South America quite early in the history of the tribe. The other genus, Phloeotribus, occurs mostly in America except for a few species that reached Eurasia rather recently.

## Genus PhLOEOTRIBUS Latreille

Phloiotribus Latreille, 1796, Précis des caractères génériques des insects, p. 50; Latreille, 1802/3, Histoire naturelle, générale et particulaere des Crustacés et des lnsects 3:204 (Type-species: Hylesinus oleae Fabricius = Scolytus scarabaeoides Bernard, monobasic)
Phloeotribus Latreille, 1804, Mag. f. Insekenk. 3:108 (Justified emendation, Internat. Comm. Zool. Nomencl. 1979:132)
Phloeophthorus Wollaston, 1854, Insecta Maderensia, p. 299 (Type-species: Phlocophthorus perfoliatus

Wollaston, monobasic); Blackman, 1943, Proc. U.S. Nat. Mus. 94:384. Synonymy

Dryotomus Chapuis, 1869, Synopsis des Scolytides, p. 46 (Type-species: Dryotomus puberulus Chapuis, monobasic) (preoccupied); Schedl, 1962, Beitr. Ent: 12:487. Synonymy
Phthorophleous Rey, 1883, Rev. d'Ent. 2:128 (Type-species: Phloeophthorus spinulosus Rey, monobasic); Blackman, 1943, Proc. U.S. Nat. Mus. 94:384. Synonymy
Elzearius Guillebeau, 1893, Ann. Soc. Ent. France 62:64 (Type-species: Elzearius crenatus Guillebeau, monobasic); Balachowsky, 1949, Faune de France 50:108. Synonymy
Eulytocerus Blandford, 1897, Biol. Centr.-Amer., Coleopt. $4(6): 161$ (Type-species: Eulytocerus championi Blandford, monobasic); Wood, 1977, Great Basin Nat. 37:38.3. Synonymy
Comesiella Del Guercio, 1925, Atti Roy. Acad. Georgofilo (Florence) 22:218 (Type-species: Comesiella sicula Del Guercio = Bostrichus brevicollis Kolenati); Balachowsky, 1949, Faune de France 50:112. Synonymy
Dryotomicus Wood, 1962, Great Basin Nat. 22:76 (replacement for Dryotomus Chapuis)
Diagnosis. - This widely distributed, highly diversified, actively evolving genus is unique among the Hylesininae in having the antennal club divided into three movable segmental units that often have the inner margin very strongly extended in a pseudolammelate arrangement. Among American species this genus is allied to Chramesus LeConte, from which it is easily distinguished by the very different antennal club, by the broader third tarsal segments (variable), and usually by the hairlike vestiture.

Description.- Length $1.2-4.0 \mathrm{~mm}$, body moderately slender to very stout; color dark brown to black. Frons dimorphic, male variously impressed to concave, female convex. Eye entire. Antennal scape long; funicle 5segmented; club divided into three segmental units with median margin weakly to very strongly extended. Pronotum wider than
long, armed or not. Scutellum small, visible. Elytral bases each armed by 9 to 16 coarse crenulations; striae weakly to strongly impressed, punctures usually coarse; interstriae usually coarsely sculptured; declivity convex, steep, conservatively sculptured. Tibiae rather broad, bearing several small teeth; third tarsal segments varying from slender to deeply bilobed.

Distribution.- Worldwide. A large number of names have been published for species in this genus; however, the amount of published and unpublished synonymy is so excessive an accurate estimate of valid species is impossible. In North and Central America 27 species were recognized.
Biology.- The winter is passed in northern areas by at least two species, frontalis
and liminaris, as adults in special hibernation tunnels in living tissue. Adults of lecontei have been taken in extended larval mines and also in incomplete parental egg galleries. The male begins a new attack and is usually joined by a female before he reaches the cambium of the host. A biramous gallery system is constructed either transversely or diagonally with respect to the grain of the wood, which it engraves rather deeply. The egg niches are usually large and close. Larval mines are usually long, primarily in the phloem tissues, and wander excessively, although they tend to radiate from the parental tunnels parallel to the grain of the wood. Two generations annually occur in the United States for most species.

## Key to the Species of Phloeotribus

1. Pronotum entirely devoid of asperities, rarely with a few small granules (hystrix); elytral vestiture abundant, confused at least on disc (uniseriate in simplex, squamosus); interstriae 9 usually not elevated or strongly serrate (except
hystrix) ..................................................................

- Pronotum asperate at least at anterolateral angles; elytral vestiture in uniseriate rows (except furous, scabratus, scabricollis); interstriae 9 commonly narrowly elevated and serrate

2(1). Elytral vestiture more abundant, confused on disc; elytral declivity variously
modified; usually much larger than 1.5 mm

- Elytral vestiture entirely limited to uniseriate interstrial rows of flattened bristles or scales; smaller than 1.5 mm
3(2). Elytral setae of two types, some short and more abundant, others longer and forming a more or less median row on each interstriae and 9 much larger than those of other interstriae; pronotal punctures shallow, much larger; Costa Rica; 1.7-2.0 mm equally armed by minute tubercles; pronotal punctures fine elytra almost evenly costate; male frontal excavation extending to vertex; body stouter; Costa Rica to Panama; $3.6-3.7 \mathrm{~mm}$ Interstriae with at least a few granules or crenulations; basal margins of elytra clearly crenulate; male frontal excavation less extensive, ending at or slightly above upper level of eyes; body slightly more slender

[^4]- Larger; rows of erect interstrial setae hairlike on declivity; discal interstriae with broad, confused crenulations, some as wide as interstriae, comparatively few punctures evident; Costa Rica; Clusia, Podocarpus; 3.4-4.0 mm

7(3). Segments of antennal club not more than twice as wide as long; submarginal crenulations at elytral bases obsolete; punctures on basal half of pronotum rather coarse; Quercus; Durango to Hidalgo; 1.8-2.1 mm
Segments of antennal club more than four times as wide as long; a few submarginal crenulations at elytral bases rather well developed: punctures on basal half of pronotum rather fine
8(7). Declivital bristles confused in female; declivital interstriae 1 and 3 rather coarsely dentate in male; male frons rather broadly, deeply impressed, with a moderately large, impunctate, epistomal callus; Chiapas to Panama; 1.5-2.5 mm

- Declivital setae in uniseriate rows in both sexes; declivital tubercles small, rounded in both sexes; male frons shallowly impressed on a limited area with or without an epistomal callus
$9(8)$. Declivital setae long and slender, little if any stouter than on disc, on declivity at least one and one-half times as long as distance between rows; tubercles on declivital interstriae 2 similar to those on 1 and 3; pronotal punctures slightly larger, shallow; Manitoba to Mississippi and east to Atlantic Coast; Prunus; $1.9-2.3 \mathrm{~mm}$
Declivital setae much stouter than those on disc, slightly shorter than distance between rows; tubercles on declivital interstriae 2 usually obsolete (very small granules in some females); pronotal punctures smaller, deeper; North Dakota to Chiapas; Prunus $1.8-2.8 \mathrm{~mm}$
10(2). Color brown; declivital bristles flattened, at least eight times as long as wide, slightly longer than distance between rows; Panama; $1.3-1.5 \mathrm{~mm}$
- Color black; declivital scales about three times as long as wide, two-thirds as long as distance between rows; Costa Rica; 1.2-1.3 mm
11(1). Lateral margin of male frons armed by a pair of large, sharply pointed tubercles at level of antennal insertion, scape devoid of a large tuft of hair (a small tuft in texanus); segments of antennal club usually less than three times as wide as long, terminal segment widest on apical third, apex usually broadly rounded (from Canada and United States, except destructor)
- Lateral margin of male frons usually elevated but unarmed; male scape bearing a tuft of long hair (small in scabratus, scabricollis, furvus); segments of antennal club usually much more than three times as wide as long, terminal segment widest near middle, narrowly rounded at its apex (from Mexico and Central America, except scabricollis)
12(11). Interstriae 9 moderately to strongly convex and serrate, serrations continuing without interruption at or near declivital base to suture
Interstriae 9 weakly or not at all convex, serrations, if present, interrupted by interstriae 2 before attaining suture
13(12). Interstriae 3 and 9 slightly elevated and apically confluent, combined elevation continuing above apex to suture, 2 terminating before apex; vestiture rather coarse; discal interstriae at most finely granulate; on conifers
- Interstriae 9 rather strongly elevated, joining costal margin before attaining suture, 2 terminating at apex; vestiture rather fine; discal interstriae rather coarsely crenulate; on broadleaf trees
14(13). Declivital interstriae 1 and 3 convex, 2 impressed or flattened at least on lower half, its tubercles reduced, usually obsolete on lower half; strial punctures usually smaller, vestiture coarser; S British Columbia and S Alberta to Arizona and New Mexico; Abies, Pseudotsuga, Picea; 1.6-2.4 mm ............. I1. lecontei Schedl
- Declivital interstriae 1 to 3 about equally convex, 2 serrate to its apex; strial punctures coarser, deeper, vestiture finer; Yukon Territory to Quebec and
Maine; Picea; $2.0-2.5 \mathrm{~mm}$ Maine; Picea; $2.0-2.5 \mathrm{~mm}$

12. piceae Swaine

15(13). Declivital interstriae 1 to 9 tuberculate; posterior area of pronotum rather closely, coarsely punctured, interspaces marked by minute impressed points; Kansas and Texas to Pennsylvania and South Carolina; Morus, Celtis 1.7-2.4 mm

13. frontalis (Olivier)

- Declivital interstriae 1 to 4 devoid of tubercles; posterior area of pronotum very coarsely, closely, punctured, very narrow interspaces devoid of points; Michoacán; Prunus; 1.8-2.4 mm

14. destructor Wood

16(12). Declivital interstriae all armed by small rounded granules; striae feebly if at all impressed, punctures rather small, narrower than width of interstriae; interstrial granules on dise small, about half as wide as interstriae; North Dakota and Texas to Pennsylvania and Florida; Celtis; 1.2-1.6 mm
15. dentifrons (Blackman)

- Declivital interstriae $1,3,5,7$, and 9 bearing moderately large, pointed teeth; discal striae impressed toward declivity, punctures coarse, deep, wider than interstriae; discal interstrial granules as wide as interstriae; Nuevo León and Texas to South Carolina and Florida; Celtis, Condalia; $1.5-1.9 \mathrm{~mm}$

17(11). Posterior margin of pronotum almost straight, not noticeably produced posteriorly on median fourth (slightly produced in demessus), scutellar notch smaller, more acute, less than three times as deep (including scutellum) as width of scutellum; body more slender, at least 1.8 times as long as wide; smaller, 1.4-2.4
$\mathrm{mm} . . . . . . . . . . . . . . . . . ~$ mm

- $\quad$ Declivital interstriae 9 strongly elevated posteriorly, joining costal margin without interruption and continuing to sutural apex ..... 22
19(18). Elytral vestiture abundant, confused on disc, very fine to slender on pronotum ..... 20
Elytral vestiture consisting of rows of stout, uniseriate, interstrial bristles ondisc and declivity, pronotal setae equally stout2I
20(19). Smaller; elytral vestiture hairlike at base, slender bristles on declivity; declivi- tal vestiture confused; Ohio to Illinois; Ptelea, Staphylea; $2.0-2.3 \mathrm{~mm}$

21(19). Discal interstriae smooth and shining except for uniseriate granules; basal margin of pronotum essentially straight; Jalisco to Costa Rica; Ficus, Celtus, Serjania; 1.4-1.9 mm

- Discal interstriae with numerous impressed points toward base, becoming minutely granulate toward and on declivity, dull; pronotum slightly produced posteriorly in median area; Veracruz to Panama; $1.6-2.3 \mathrm{~mm}$

22(18). Declivital interstriae 2 and 4 devoid of granules or tubercles, 1 and 3 strongly tuberculate, 9 more strongly elevated; Oaxaca to Colombia; 1.9-2.4 mm
21. armatus Blandford

- Declivital interstriae 1 to 8 equally, rather finely tuberculate; interstriae 9 somewhat less strongly elevated
23(22). Pronotal asperities confined to small area on anterior fourth, punctures smaller, more widely spaced; anterior margin of pronotum armed by very coarse teeth; interstrial crenulations on disc smaller, more widely spaced; Panama to Colombia and Venezuela; Brosimum; $2.0-2.5 \mathrm{~mm}$

22. biguttatus Blandford

- Pronotal asperities more numerous, more widely distributed on at least anterior half; anterior margin unarmed or finely, irregularly armed by one to three teeth; discal interstrial crenulations larger, closer, Veracruz to Costa Rica
24(23). Interstriae 9 elevated and serrate to striae 3; male epistoma with a very strongly elevated, straight, transverse carina on median fourth; pronotal disc reticulate; Guatemala to Venezuela; $2.0-2.5 \mathrm{~mm}$................. 23. subovatus Blandford
- Interstriae 9 elevated and serrate to suture; male epistoma with a procurved, moderately elevated, transverse carina on more than median half; pronotal disc smooth; Veracruz to Peru and Brazil; Celtis, Croton, Ficus, etc.; 1.9-2.4 mm ....
$\qquad$
25(17). Elytral striae almost as wide as interstriae, interstrial crenulations almost as wide as interstriae (except on basal half of 2), interstrial setae uniseriate; Veracruz to Costa Rica; $2.4-3.1 \mathrm{~mm}$

25. maurus Wood

- Elytral interstriae at least twice as wide as striae, interstrial crenulations less than half as wide as discal interstriae, interstrial setae confused on basal half of 2-4
26(25). Pronotal and elytral surfaces rugose-reticulate; declivity with rows of interstrial tubercles smaller, many obsolete, setae on discal interstriae 3-10 uniseriate except at base; Chiapas to Brazil and Peru; Brosimum; 2.6-3.3 mm

26. pilula Erichson

- Pronotal and elytral surfaces shining, not reticulate; declivity with rows of interstrial tubercles larger; setae on all discal interstriae confused; Guatemala to Panama; 2.8-3.3 mm

## 1. Phloeotribus hystrix Wood

Phloeotribus hystrix Wood, 1969. Brigham Young Univ. Sci. Bull. 10(2):7 (Holotype, male; Río Damitas, Dota Mounains, San José, Costa Rica; Wood Coll.)
Diagnosis.-Although this species is allied to discrepans Blandford, it is not closely related. It is distinguished from Blandford's species by the much wider discal interstriae,
by the larger pronotal punctures, and by the rather coarse declivital denticles on interstriae 7 and 9 .

Male.- Length $1.7-2.0 \mathrm{~mm}, 2.1$ times as long as wide; color brown.

Frons very shallowly concave below upper level of eyes, sides weakly elevated and armed at level of antennal insertion by a pair of small tubercles; surface coarsely reticulate,
punctures small, obscure; vestiture sparse, moderately long, coarse. Antennal club with segment 1 three times as wide as long.

Pronotum 0.9 times as long as wide; widest on basal half, sides weakly arcuate, almost parallel on basal half, then convergent to constriction just behind broadly rounded anterior margin; surface coarsely, deeply, closely, irregularly punctured, anterior and lateral areas subgranulate or even very finely asperate; vestiture short, stout, abundant, almost scalelike.

Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal three-fourths, obtusely angulate behind, with lateral declivital spines interrupting profile; striae sharply impressed, punctures large, deep, distinct; interstriae distinctly narrower than striae, irregular, each with a median row of fine setiferous granules and additional subgranulate setiferous punctures on each side. Declivity steep, convex; interstriae 1 weakly elevated, 5 with two, 7 with three, 9 with five large pointed tubercles, posteriormost one on each interstriae longer, 9 elevated slightly to final spine; costal margin near apex slightly elevated. Vestiture consisting of rather abundant interstrial subsquamose bristles, short except median row twice as long, erect; equally abundant on disc and declivity.
Female.-Similar to male except frons weakly convex, unarmed; pronotum more nearly asperate in lateral areas.

Distribution.- Costa Rica.
COSTA RICA: Rio Damitas, Dota Mountains, San José, 18-II-64, 250 m , No. 437, S. L. Wood.

Biology.- The transverse, biramous egg galleries were primarily in the phloem tissues of the stump 20 cm in diameter of an unidentified tree.

Notes.- The above treatment was based on the type series of 22 specimens.

## 2. Phloeotribus championi (Blandford)

Eulytocerus championi Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):161 (Holotype, male; Volcán de Chiriquí, Chiriquí, Panama; British Mus. Nat. Hist.)
Eulytocerus substriatus Schedl, 1935, Rev. de Ent. 5:344 (Holotype, male; Turrialba, Costa Rica; Schedl Coll.); Wood, 1977, Great Basin Nat. 37:387. Synonymy

Diagnosis. - This species is distinguished from nubilus Blandford and atavus Wood by the costate basal margins of the elytra, by the absence of granules and crenulations from the elytral interstriae, and by the much more extensive excavated area on the male frons.

Male.- Length $3.6-3.7 \mathrm{~mm}, 1.8$ times as long as wide; color very dark brown, almost black.

Frons shallowly concave from vertex to epistoma from eye to eye (transversely flat to weakly concave between eyes), margins from level of antennal insertion to epistoma elevated, partly costate; a rather deep, short, median groove just above level of antennal insertion dividing a transverse callus; surface smooth and shining, rather densely, finely, uniformly punctured on upper two-thirds, less closely punctured on lower third; vestiture of fine, rather short, moderately abundant hair.

Pronotum 0.87 times as long as wide; widest one-third pronotum length from base, sides strongly arcuate from base, rather narrowly rounded in front; surface smooth, shining, densely, deeply, rather finely punctured, entirely devoid of asperities, median line impunctate on basal half. Disc with a few stout setae, more abundant at margins.

Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; basal margins costate, submarginal crenulations absent; striae distinctly, rather weakly impressed except more strongly impressed toward declivity, punctures varying from almost round to subquadrate, rather close; interstriae two to three times as wide as striae, moderately convex, shining, irregularly undulating or wrinkled on basal two-thirds, punctures rather fine, abundant, confused, many of them associated with irregular, transverse, impressed lines except near declivity. Declivity rather steep, convex; sculpture as on posterior part of disc. Vestiture of moderately abundant, small, erect scales and interstrial rows of longer bristles; each bristle three to five times as long as scales, half to two-thirds as long as distance between rows, similarly spaced within a row; bristles shorter on lower declivity.

Distribution.- Costa Rica to Panama.

COSTA RICA: Turrialba, 800 m , SLG. Schild. PAN AMA: Volcán de Chiriquí, $3500-4000 \mathrm{ft}$ (about 1200 m ), G. C. Champion.

Notes.- The above treatment was based on the holotypes of championi ( 3.7 mm ) and biseriatus $(3.6 \mathrm{~mm})$. The frontal setae and erect elytral setae of championi are very slightly longer, and the interstrial punctures of substriatus are slightly larger and associated with slightly deeper undulations of surface contour; however, on the basis of these two specimens I recognize only one species.

## 3. Phloeotribus nubilus Blandford

Phlocotribus nubilus Blandford, 1897, Biol. Centr. Amer., Coleopt 4(6):163 (Lectotype, female; Cerro Zunil, Guatemala; British Mus. Nat. Hist., present designation)
Diagnosis.- This species is allied to atavus Wood, although the relationship is not close. It is distinguished by the smaller size, by the scalelike, uniseriate rows of erect interstrial setae on the posterior half of the elytra, by the narrow, uniseriate interstrial crenulations, and by the convex area of the female frons extending well below the level of the antennal insertions.

Male.- Length $2.2-2.7 \mathrm{~mm}, 2.0$ times as long as wide; color dark reddish brown.

Frons broadly, concavely impressed from upper level of eyes to epistoma, lateral margins armed by a pair of somewhat indefinite teeth at level of antennal insertion; surface reticulate, finely, rather closely punctured. Segments of antennal club four times as wide as long; scape with a small tuft of about a dozen long setae.

Pronotum 0.85 times as long as wide; widest at base, sides rather weakly arcuate, converging slightly anteriorly, broadly rounded in front; surface obscurely reticulate, anterolateral areas with isolated, very fine asperities, punctures moderately small, shallow, close; vestiture consisting of very fine, short, hairlike setae and slightly longer, coarser bristles.

Elytra 1.45 times as long as wide, 1.9 times as long as pronotum; sides straight and parallel on basal two-thirds, moderately constricted before narrowly rounded posterior margin; scutellum small, round, scutellar notch rather deep; basal margins armed by 14 rather coarse, overlapping crenulations;
striae weakly impressed, punctures small, deep, very close, a few confluent; interstriae twice as wide as striae, weakly convex, punctures small, deep, confused, abundant, each interstriae bearing a uniseriate row of rather large subcrenulate granules, granules not more than a third as wide as an interstriae. Declivity convex, moderately steep; striae slightly deeper; interstriae as on disc except 9 weakly elevated then joining costal margin and continuing to apex. Vestiture consisting of rather abundant ground setae, hairlike at base, subplumose scales on posterior half of dise and on declivity; and uniseriate rows of longer, erect, interstrial bristles, slender at base, scalelike on declivity, on declivity twice as long as ground cover, about four times as long as wide.

Distribution.- Veracruz to Panama.
Mexico: Veracruz: Motzorongo, Flohr. GUATEmala: Cerro Zunil, G. C. Champion. Costa rica: San Vito, Puntarenas, 21-1-68, $1500 \mathrm{~m} . \mathrm{H}$. Hespenheide. PANAMA: Volcán de Chiriquí, G. C. Champion.

Notes. - The above treatment was based on the original Blandford series, and one additional specimen from Costa Rica. Because a lectotype has not been selected from the syntypic type series, I here designate as the lectotype of nubilus Blandford the first specimen in the series, a female from Cerro Zunil, Guatemala. This specimen has previously been regarded as the type.

## 4. Phloeotribus atavus Wood

Phloeotrihus atatus Wood, 1969, Brigham Young Univ. Sci. Bull. $10(2): 6$ (Holotype, female: Laguna Volcán Poás, Heredia, Costa Rica; Wood Coll.)
Diagnosis.- This species is allied to nubilus Blandford, but it is distinguished by the larger size, by the hairlike, longer, uniseriate, interstrial setae, and by the coarser pronotal punctures.

Male.- Length $3.4-4.0 \mathrm{~mm}, 2.0$ times as long as wide; color very dark brown.

Frons convex above eyes, flattened to impressed below; lateral margins subacutely elevated from level of antennal insertion almost to epistomal margin, area between flattened; surface subreticulate, punctures rather coarse, close, very shallow; vestiture very fine, inconspicuous. Antennal club with segment 1 three times as wide as long, about as long as scape.

Pronotum 0.96 times as long as wide; widest at or just behind middle, sides rather strongly arcuate, converging very slightly anteriorly, rather strongly constricted just behind rather broadly rounded anterior margin; surface completely devoid of asperities, reticulate, punctures rather small, very close, deep; a faint median line weakly elevated; vestiture consisting of inconspicuous, very fine, short hair.

Elytra 1.4 times as long as wide, 1.8 times as long as pronotum; sides straight and parallel on basal two-thirds, broadly rounded and with apex rather narrowly extended on median third behind; striae narrowly impressed, punctures rather obscure, interstriae twice as wide as striae, crenulate on basal half, some crenulations as wide as interstriae, elevations becoming narrower and uniseriate behind, some fine punctures also present; shining. Declivity rather steep, convex; striae impressed; interstriae convex, 1 slightly elevated on lower half, apical costal margin and posterior part of 9 also slightly elevated, each interstriae with a row of very small tubercles. Vestiture consisting of moderately sparse, small scales on posterior half of disc and on declivity, and sparse median interstrial rows of fine long hair, longest hairs equal in length to distance between rows and to adjacent hairs within a row.

Female.- Similar to male except frons convex to just above level of antennal insertion, impression less extensive, lateral margins less strongly elevated, punctures slightly deeper; elytral tubercles often very slightly larger.

Distribution.- Costa Rica.
COSTA RICA: Laguna Volcán Poás, 6-X-63, 14-VII63, 19-V111-66, 2700 m , Nos. 98 and 170 in Clusia, No. 47 in Podocarpus, S. L. Wood.
Hosts.- Clusia sp., Podocarpus oleifolius.
Biology.- The biramous egg galleries were transverse and almost entirely in the phloem. This aggressive species attacked and apparently killed several Clusia trees; they also killed several buttress roots of a large Podocarpus tree.

Notes.- The above treatment was based on the type series of 37 specimens.

## 5. Phloeotribus quercinus Wood

Phloeotrihus quercinus Wood, 1969, Great Basin Nat. 29:123 (Holotype, female; Pachuca, Hidalgo, Mexico; Wood Coll.)
Diagnosis.- This species is closely allied to pruni Wood, but it may be distinguished by the less strongly attenuate lateral extension of segments of the antennal club, by the absence of submarginal crenulations near the elytral bases, by the coarser pronotal punctures, and by the host.
Female.- Length $1.8-2.1 \mathrm{~mm}, 1.9$ times as long as wide; color black.

Frons evenly convex above level of antennal insertion, transversely impressed below, smooth epistomal margin slightly elevated; premandibular epistomal lobe small, distinct; surface strongly reticulate, punctures small, obscure, rather close; vestiture fine, hairlike, rather sparse. Antennal club with segments 1 and 2 each very slightly less than twice as wide as long.

Pronotum 0.82 times as long as wide; widest at base, sides arcuately converging to a slight constriction just before broadly rounded anterior margin; surface reticulate, devoid of all indications of asperities, punctures coarse, moderately deep, separated by distances up to diameter of a puncture; part of median line impunctate in front of middle; vestiture very fine, long.
Elytra 1.35 times as long as wide, 2.0 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; scutellum small, rounded, scutellar notch rather deep; basal margins each armed by 14 rather narrow, high crenulations, devoid of submarginal crenulations; striae weakly impressed toward declivity, punctures moderately coarse, deep, interstriae slightly wider than striae, devoid of punctures, moderately large, rounded granules somewhat confused. Declivity convex, steep; striae moderately impressed; interstriae feebly convex, not elevated, granules almost uniseriate. Vestiture consisting of fine, semirecumbent strial hair, and erect, confused interstrial setae of uniform length, fine at base, becoming stout and shorter toward declivity, each almost equal in length to width of an interstriae.
Distribution. - Durango to Hidalgo.

MEXICO: Durango: 32 km E El Salto, 17-V1-71, H . F. Howden. Hidalgo: 16 km E Pachuca, 10-Vl-67, 2600 m, No. 5, Quercus, S. L. Wood.

Ноst.-Quercus sp.
Brology.- Diagonal, biramous galleries were being cut by adult females, engraving the wood rather deeply in small branches and twigs less than 2 cm in diameter. Neither eggs nor larvae were present. It is entirely possible these were maturation feeding tunnels formed while the males were elsewhere beginning primary galleries.

Notes.- The type series of 23 specimens was used to prepare the above treatment.

## 6. Phloeotribus discrepans Blandford

Phlocotribus discrepans Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):163 (Holotype, female; Volcán de Chiriquí, Panama; British Mus. Nat. Hist.)
Diagnosis.- This species is allied to liminaris Harris and pruni Wood, but it may be distinguished by the large epistomal callus of the male, by the armature of the male declivity, and, in the female, by the confused interstrial setae on the declivity.

Male.-Length 1.5-2.5 mm, 1.9 times as long as wide; color dark brown.

Frons broadly, shallowly concave from near upper level of eyes to level of antennal insertion, median two-thirds of epistomal margin occupied by a large reticulate, impunctate callus extending to level of antennal insertion; remaining surface reticulate, punctures fine, deep, rather close; vestiture of fine, short, inconspicuous hair. Segment 1 of antennal club 3.8 times as wide as long.

Pronotum 0.88 times as long as wide; widest at base, sides arcuately converging to constriction just before broadly rounded anterior margin; entire surface reticulate, punctures rather fine, shallow to moderately deep, rather close, part of those (perhaps onefourth) on anterior two-thirds very finely asperate, asperities not larger in lateral areas; vestiture consisting of rather abundant, fine, short hair.

Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on posterior two-thirds, rather broadly rounded behind, posterior profile interrupted by several declivital teeth; scutellar notch rather shallow, broad; anterior margins
each armed by 11 to 13 coarse, overlapping crenulations; striae moderately impressed, punctures rather coarse, deep, distinct; interstriae wider than striae, slightly convex, punctures fine, deep, confused, their anterior margins weakly granulate. Declivity steep, convex; strial punctures deep but smaller than on declivity; interstriae 1 and 3 moderately convex, slightly elevated, 1 armed by four, 3 by five rather coarse teeth, 2 impressed, as narrow as 1 , with a uniseriate row of punctures, $5,7,8$, and 9 each with one to about four small tubercles. Vestiture of suberect, stout, abundant bristles of uniform length on dise and declivity, each bristle equal in length to width of interstriae.

Female.- Similar to male except frons convex, epistomal margin and transverse callus just above antennal insertions slightly elevated; interstrial granules on disc conspicuously larger; declivital interstriae equally, weakly convex, each (including 2) bearing a row of small tubercles; declivital bristles confused on all interstriae except 1.

Distribution. - Chiapas to Panama.
MExiCO: Chiapas: 11 km E San Cristóbal, 13-V-69, D. E. Bright. GUATEM1ALA: Quezaltenango, Quezaltenango, 26-V-64, 1700 m , No. 626, S. L. Wood; Volcán de Agua. Esquintla, 19-V-64, 1000 m, No. 614, S. L. Wood. panama: Cerro Punta (Volcán de Chiriqui), Chiriquí, 11-1-64. 1800 m , Nos. 389, 398, 417, 421, S. L. Wood.

Hosts. - Several unidentified tree species.
Biology.- Similar to liminaris.
Notes. - The above treatment was based on my female topotypic homotype and on 240 additional specimens. A distinctive group is formed within the genus by quercinus, discrepans, liminaris, and pruni.

## 7. Phloeotribus liminaris (Harris) Figs. 89, 90

Tomicus liminaris Harris, 1852, A treatise on some of the insects of New England injurious to vegetation, p. 79 (Holotype, female; New England; Mus. Comp. Zool.)
Phthorophloeus mississippiensis Blackman, 1921, Mississippi Agric. Expt. Sta. Tech. Bull. 10:4 (Lectotype, female; Agricultural College or Starkville, Mississippi; U.S. Nat. Mus., 56930, designated by Wood, 1971, Great Basin Nat. 31:151). Synonymy
Diagnosis.- This species is very closely related to pruni Wood, but it may be distinguished by the much finer, much longer pubescence, by the larger, less deeply impressed pronotal punctures, by the somewhat coarser
tubercles on declivital interstriae 2 , and by the less strongly impressed male frons and larger epistomal callus.

Male.- Length 1.9-2.3 mm, 1.9 times as long as wide; color dark brown.

Frons convex, a very feeble impression immediately above transverse callus at level of antennal insertion; epistomal margin slightly elevated with a moderately large, reticulate callus on median third (much as in discrepans) extending toward transverse callus above; surface elsewhere reticulate, punctures small, rather close, somewhat obscure; vestiture hairlike, fine, moderately long, inconspicuous. Antennal club segment 1 four times as wide as long.
Pronotum 0.80 times as long as wide; outline as in discrepans; entire surface reticulate, punctures moderately large, shallow, rather close, not at all granulate or asperate; vestiture of rather long, fine, abundant hair.

Elytra 1.3 times as long as wide, 1.8 times as long as pronotum; sides very feebly arcuate, diverging very slightly to declivital base, rather broadly rounded behind; scutellar notch rather shallow, broad; basal margins each armed by 10 to 11 coarse, overlapping crenulations; striae weakly impressed, punctures coarse, deep; interstriae as wide as striae, all punctures largely replaced by small, rounded, confused granules. Declivity steep, convex; striae more narrowly impressed, punctures very slightly smaller, deeper; interstriae slightly narrower than striae, convex, 1 weakly elevated, each equally armed by a uniseriate row of rounded tubercles. Vestiture hairlike, very slightly coarser on declivity, length of each seta one to two times greater than width of one interstriae.

Female.-Similar to male except frons more nearly convex, reticulate epistomal

Fig. 89. Phloeotribus spp. antennae and protibiae: 1, 7, rhododactylus; 2, 8, piccac; 3, 9, frontalis: 4, 10, liminaris: 5, 11 caucasicus; 6, 12, scarabaeoides. (After Swaine 1911:224.)
callus absent; tubercles on elytral declivity evidently slightly smaller.

Distribution. - Manitoba to Mississippi and east to the Atlantic Coast.
CANADA: Manitoba, New Brunswick, Ontario, Quebec. USA: Connecticut, District of Columbia, Florida, lowa. Kentucky, Massachusetts, Michigan. Mississippi, New Hampshire, New Jersey, New York, North Carolina, Ohio, Pennsylvania, South Carotina, West Virginia.

Hosts. - Prunus americana, P. angustifolia, P. persica, P. serotina.

Brology. - This is the peach tree bark beetle that occasionally damages peach, cherry, and plum trees in the eastern United States and eastern Canada. Most of the adults overwinter in hibernation tumnels in healthy or injured bark of the host tree; a few evidently pass the winter in the brood galleries. In the spring the beetles emerge and attack unhealthy, injured, or cut limbs of the host, where biramous, transverse galleries engrave the wood rather deeply. Larval mines tend to follow the grain of the wood. Normally there are two generations each year, with at least a partial third generation in the southern part of its range.

Notes.- The female holotype of liminaris has the pronotum damaged, but it is easily recognized as this species. The above treatment was based on my female homotype from Burning Well, Pennsylvania, on the type series of mississippiensis, and on 313 other specimens. It is replaced in the west by pruni.

## 8. Phloeotribus pruni Wood

Phlocotribus pruni Wood, 1956, Canadian Ent. 88:253 (Holotype, female; Chihuahua, Chihuahua, Mexico; Snow Ent. Coll., Univ. Kansas)
Diagnosis.- This species is very closely related to liminaris (Harris), but it may be distinguished by the much shorter, stout vestiture, particularly on the elytral declivity, by the finer, less deeply impressed pronotal punctures, by the somewhat finer punctures on declivital interstriae 2 , and by the more strongly impressed male frons with a considerably larger median, epistomal callus.

Male.- Length $1.8-2.8 \mathrm{~mm}, 2.0$ times as long as wide; color dark brown.

Frons shallowly concave on central half, with a pair of lateral calluses just above level
of antennal insertion as in liminaris but not connected on median third; epistomal callus reticulate, extending on median half to level of antennal insertion, much larger and more conspicuous than in liminaris, remaining surface reticulate (north) to subrugulose (south), rather finely, obscurely punctured; vestiture of fine, sparse, inconspicuous hair. Segment 1 of antennal club 4.0 times as wide as long.

Pronotum 0.80 times as long as wide; as in liminaris except surface usually a little more coarsely sculptured with punctures tending to average slightly smaller, vestiture shorter.

Elytra 1.3 times as long as wide, 1.8 times as long as pronotum; as in liminaris except granules on declivital interstriae averaging smaller, particularly on 2 , vestiture stout, of uniform length, bristles not longer than distance equal to width of one interstriae.

Female.-Similar to male except frons more nearly convex, upper calluses higher, epistomal callus present, much smaller, its surface indistinctly reticulate.

## Distribution. - North Dakota to Chiapas.

USA: Arizona: 24-111-41, peach. Colorado: Fort Collins, 30-VIII-50, Prumus virginiana. S. L. Wood; Boulder, Hopk. U.S. 432, Prumus, A. D. Hopkins; N. Chevenne Canyon, 27-V11-15, P. cmarginata, G. Hofer. New Mexico: Fairacres. 30-1X-43, peach; Nogal; Silver City, 19-1X55. peach: State College, 23-VII1-16. North Dakota: Bottineau Co., 16-VIl-71, Prumus virginiana, D. A. Tagstad; Hettinger, 16-VII-71, Prumus, M. E. McKnight: McHenry Co.; 30-V-70, D. A. Tagstad. NEXICO: Chiapas: Mt. Tzontehuitz, 26-V-69, D. E. Bright. Chihuahua: 24 km N Chihuahua, 29-VIl1-53, Prumus, S. L. Wood: Maguarichic, 13-VIl-60, peach, S. L. Wood. Durango: Durango, $\mathrm{X}-55$, durazno, E. Jiminez. Jalisco: Guadalajara. Hidalgo: 8 km W Tulancingo, ll-V1-67. wild cherry, S. L. Wood. Michoacán: 19 km E Carapan, 18-V1-65. Prunus, S. L. Wood. Nuevo León: Cerro Potosi, 2-V-71, D. E. Bright.

Hosts.- Prumus persica, $P$ virginiana, $P$. sp.

Biology.- Apparently the habits are as in liminaris. This rather aggressive species was found in peach and wild cherry at every Mexican locality where an effort was made to locate it. Although commercial orchards were not examined, it probably will be at least as important economically as liminaris is in the eastern United States.
Notes.- The above treatment was based on the four paratypes in my collection and on 236 additional specimens. Specimens from the area north of Durango tend to be slightly
smaller and more finely sculptured than those from further south.

## 9. Phlocotribus simplex Wood

Phlocotribus simplex Wood, 1967, Great Basin Nat. 27:95 (Holotype, female, Fort Clayton, Canal Zone, Panama; Wood Coll.)
Diagnosis.- This species is not clearly related to any species known to me, but evidently it is more nearly allied to squamatus Wood than to other Central American species.
Female.- Length 1.3-1.5 mm, 2.1 times as long as wide; color brown.

Frons convex, with a transverse callus at level of antennal insertion; surface coarsely reticulate, with rather coarse, deep, moderately abundant punctures; vestiture fine, hairlike, inconspicuous. Segment 1 of antennal club about twice as wide as long.

Pronotum 0.9 times as long as wide; widest one-fourth length from base, sides feebly arcuate on basal half, rather strongly constricted just behind broadly rounded anterior margin; surface unarmed, reticulate, punctures small, deep, separated by distances one to three times diameter of a puncture; vestiture consisting of short, fine, and longer, coarse, hairlike setae.
Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; scutellar notch very shallow; basal margins armed by a single row of 9 rather high crenulations, submarginal crenulations absent; striae not impressed, punctures deep, coarse; interstriae as wide as striae, almost flat and smooth, with median rows of small setiferous granules. Declivity steep, convex, rather narrow; striae and interstriae narrower than on disc. Vestiture consisting of rows of fine, recumbent, strial hair, and longer, erect, uniseriate rows of interstrial bristles, each bristle somewhat flattened at its apex and spaced in rows and between rows by distances about equal to length of a bristle.

## Distribution.- Panama.

PANAMA: Fort Clayton, Canal Zone, 22-XII-63, 30 in, woody vine, S. L. Wood; Barro Colorado Island, Canal Zone, 27 -XII- $63,60 \mathrm{~m}$, woody vine. S. L. Wood.
Host.- A large woody vine (liana).
Biology. - Little could be determined concerning the habits from the partly decomposed host except that the brood penetrated
deeply into the tissues. Whether the parental or larval mines had or had not been formed initially in the cambium could not be determined. The host was $5-10 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the type series of 13 female specimens.

## 10. Phloeotribus squamatus Wood

Phloeotribus syuamatus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. IO(2):7 (Holotype, male: Tapantí, Cartago, Costa Rica; Wood Coll.)
Diagnosis. - This unique species is distinguished from other representatives of this genus by the small size, by the unarmed pronotum, by the short, uniseriate, squamose, interstrial vestiture, and by the shallowly impressed male frons.
Male.- Length $1.2-1.3 \mathrm{~mm}, 2.1$ times as long as wide: color black, with white squamose vestiture.

Frons shallowly concave from upper level of eyes to epistoma, lateral margins not acutely elevated or armed; epistomal margin weakly elevated, and with a median tubercle; surface coarsely reticulate; vestiture inconspicuous, mostly confined to marginal areas. Antennal club small, compact; segment 1 about 1.5 times as wide as long.

Pronotum 0.8 times as long as wide; widest just behind middle, sides moderately arcuate. moderately constricted just behind rather narrowly rounded anterior margin; surface rather coarsely reticulate, including punctures, with close, coarse, shallow punctures; vestiture consisting of suberect, short, stout, almost scalelike bristles, most of them about three times as long as wide.

Elytra 1.4 times as long as wide, 1.9 times as long as pronotum; scutellar notch rather shallow; basal margins armed by 9 coarse, rather high crenulations, submarginal crenulations not evident; striae weakly impressed, punctures large, rather deep; interstriae about half as wide as striae, almost restricted to a narrow row of closely set, subvulcanate, squamiferous punctures. Declivity rather steep, convex; striae somewhat narrower and deeper than on disc. Vestiture consisting of uniseriate rows of erect scales, each scale less than twice as long as wide; separated from

Fig. 90. Scolytidae spp.,: 1, Phlocotribus dentifrons; 2, Phlocotribus liminaris; 3, Phlocosinus dentatus: 4, Pseudopityophthorus asperulus; 5, Pityophthorus lautus; 6, Pityophthorus scriptor. (Blackman 1921:11.)
adjacent scales in same row by distances equal to less than the width of a scale, and between rows by distances equal to almost twice length of a scale.

Female.-Similar to male except frons convex, median epistomal tubercle absent; vestiture of pronotum and elytra very slightly more slender.

## Distribution.- Costa Rica.

COSTA RICA: Tapantí, Cartago, 8 -VII-63, 1300 m , dying tree, S. L. Wood.
Biology. - The only two known specimens were just entering the bark of a limb of the unidentified host tree.

Notes. - The above treatment was based on the male holotype and the female allotype. Specimens in a series taken from Inga at Colonia Tovar, Aragua, Venezuela, are $1.3-1.7 \mathrm{~mm}$ in length, but appear to be of this species.

## 11. Phloeotribus lecontei Schedl

Phlocotribus puberulus LeConte, 1879, nec Chapuis 1869, U.S. Dept. Interior, Geol. Geograph. Surv. Bull. $5(3): 519$ (Holotype, male; La Veta Pass, Col-
orado: Mus. Comp. Zool) orado; Mus. Comp. Zool.)
Phloootribus lecontei Schedl, 1962, Beitr. Ent. 12:487 (replacement name)
Diagnosis.- This species is very closely related to piceae Swaine, but it is distinguished by the depressed, often flattened declivital interstriae 2 on the lower half, with the tubercles reduced, by the somewhat smaller strial punctures, and by the coarser vestiture. The European spinulosus Rey is a closely related, more finely sculptured species.

Male.- Length $1.6-2.4 \mathrm{~mm}, 2.2$ times as long as wide; color very dark brown.

Frons deeply, rather narrowly concave from upper level of eyes to epistoma, lateral margins at level of antennal insertion bearing a pair of rather large, pointed tubercles; surface rather smooth, punctures fine, sparse, a few isolated granules above; epistomal margin extended on median third into a moderately large premandibular lobe; vestiture rather sparse, coarse, moderately long, uniformly distributed. Segment 1 of antennal club twice as wide as long.

Pronotum 0.84 times as long as wide; widest very slightly behind middle, sides rather strongly arcuate, moderately
constricted just before rather narrowly rounded anterior margin; surface very minutely granulate, punctures moderately large, rather close, often obscure, some punctures on anterior half with their anterior margins very finely granulate; vestiture of coarse, moderately long bristles.

Elytra 1.5 times as long as wide, 2.0 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind, several serrations interrupt posterior profile; scutellar notch rather narrow, moderately shallow; basal margins each armed by 10 coarse crenulations and three submarginal ones near scutellum; striae very weakly impressed, punctures moderately coarse, deep; interstriae as wide as striae, weakly convex, minutely granulose, punctures very finely granulate. Declivity convex, moderately steep; striae very slightly more deeply impressed; interstriae 1, 3, and 9 moderately elevated, 3 and 9 join apically and continue to 1 before apex, 2 narrowed and usually flattened on lower half; all interstriae uniseriately tuberculate except lower half of 2 , serrations on $1,3,9$, and costal margin near apex, larger. Vestiture consisting of very fine, short, strial hair and uniseriate rows of erect, interstriae bristles, each bristle as long as distance between rows, more closely spaced within each row; a supplemental row of bristles on declivital interstriae 1.

Female.- Similar to male except frons convex, with a slight median impression on upper half; elytral tubercles often slightly
larger.

Distribution.-British Columbia and Alberta to Arizona and New Mexico.

CANADA: Alberta: Banff. British Columbia: Kootenay Pass near Creston. USA: Arizona: Alpine, Chiricahua Mts., Graham Mts., Santa Catalina Mts. California: Arcata. Colorado: Del Norte, Fort Collins, Fort Garland, Indian Creek, New Castle, Poudre Canyon, Rabbit Ears Pass. Idaho: Franklin Co. Montana: Glacier
N. P. New Mexico: Capitan, Cloudcroft N. P. New Mexico: Capitan, Cloudcroft, Sacramento Mts., Sandia Mts.. Santa Fe Ski Basin. Oregon: Dixie Pass, Gold Lake. Utah: Alta, Ashley N. F., Bryce Canyon N. M., Logan Canyon, Parowan Canyon, Settlement Creek in Tooele Co., Wolf Creek Pass.

Hosts.- Abies lasiocarpa, Picea englemannii, P. pungens, Pseudotsuga menziesii.

Biology.- This monogamous species evidently prefers shaded out branches of large living trees, although it occasionally occurs in branches of fallen trees or slash. The male
constructs the entrance tunnel and bases of the biramous egg galleries; the female cuts the remainder of the two egg galleries. The tunnels most commonly cut obliquely across the grain of the wood, though they vary from transverse to almost longitudinal. The winter is passed mostly as young adults or almost fully grown larvae; some of the adults are in the brood galleries, others in what appeared to be special hibernation or maturation tunnels, and others in newly formed parental galleries. Adults and larvae of almost all sizes can be found at any time during the year. Evidently two generations are produced each year at lower elevations. The species is not aggressive and, consequently, is of minor economic importance.

Notes.- The above treatment was based on my male homotype from Rabbit Ears Pass, Colorado, and 215 additional specimens. This species is rather variable within a series. For this reason geographical variations were difficult to detect. The most distinct variation was the almost completely transverse parental galleries of the Graham Mountain, Arizona, series.

## 12. Phloeotribus piceae Swaine Fig. 89

Phlocotribus piceae Swaine, 1911, Canadjan Ent. 43:220 (Lectotype, female; Ste. Anne de Bellvue, Quebec; Canadian Nat. Coll., designated by Bright, 1967, Canadian Ent. 99:677)
Diagnosis.- This species is very closely related to lecontei Schedl, but it is distinguished by the more coarsely, deeply impressed strial punctures, by the equally convex, serrate declivital interstriae 1 to 3 , and by the finer vestiture.

Male.- Length $2.0-2.5 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown.

Frons as in lecontei. Pronotum as in lecontei except surface more nearly shining, punctures evidently averaging slightly smaller.

Elytra as in lecontei except strial punctures larger, deep, interstriae smoother; declivital interstriae 1 to 3 equally convex and serrate, denticles on 2 continued to its apex, all declivital tubercles coarser than in lecontei; vestiture much finer, interstrial setae of eastern specimens almost as fine as those on striae.

Female.- Similar to male except frons planoconvex, with a transverse callus at level
of antennal insertion; elytral tubercles very slightly larger.

Distribution.- Yukon Territory to Quebec and Maine.

ALASKA: Hope, 1978, pheromone trap, R. A. Werner. CANADA: Manitoba: Riding Mts. Northwest Territories: Aklivak, Yellowknife. Ontario: Sudbury. Quebec: Gaspé Co., Isle Perrot, Ste. Anne de Bellvue. Yukon Territory: Fortymile. USA: Maine: Brunswick, Camp Caribou, Orono. Minnesota: Duluth. New York: Cranberry Lake.

## Host.- Picea glauca.

Biology. - Evidently similar to lecontei.
Notes. - The above treatment was based on the lectotype, on 8 paratypes, and on 70 other specimens.

## 13. Phloeotribus frontalis (Olivier) Fig. 89

Scolytus frontalis Olivier, 1795, Entomologie, Coleopt. 4(78):13 (Amerique septentrionale; presumably in Paris Mus. but not located)
Bostrichus frontalis: Fabricius, 1801, Systema Eleutheratorium 1:389.
Phloeotribus frontalis: Zimmerman, 1868, Trans. Amer. Ent. Soc. 2:149.
Phlocophthorus granicollis Eichhoff, 1868, Berliner Ent. Zeitschr. 12:149 (Lectotype, male; Carolina boreale, specimen labeled "Am. Bor"; U.S. Nat. Mus., present designation); Eichhoff, 1896, Proc. U.S. Nat. Mus. 18:608. Synonymy

Phloeophthorus moriperda Hopkins, 1905 (preprint), Proc. Ent. Soc. Washington 7:77 (Lectotype, female; Irapuato, Guanajuato, Mexico; U.S. Nat. Mus., 7515, designated by Wood, 1971, Great Basin Nat. 31:151) Synonymy
Diagnosis.- As indicated in the above key, this species is rather closely related to destructor Wood, but it is distinguished by having declivital interstriae 1 to 4 tuberculate, by the less closely, more finely punctured pronotum with minute points densely marked in the interspaces, and by the different host and distribution.

Male.- Length $1.7-2.4 \mathrm{~mm}, 2.1$ times as long as wide; color dark brown.

Frons broadly, shallowly concave from epistoma to upper level of eyes, center subfoveately impressed, lateral margins armed by a pair of coarse, pointed tubercles at level of antennal insertion; surface finely rugulose, with a few very fine granules on upper half of sides and above eyes, several, fine, obscure punctures below; vestiture of fine, inconspicuous hair. Segment 1 of antennal club 1.6 times as wide as long.

Pronotum 0.86 times as long as wide; widest just behind middle, very slightly arcuate, rather abruptly rounded just anterior to middle, rather narrowly rounded in front; surface densely marked by fine puncturelike points in interspaces between small, moderately abundant punctures, fine, rounded granules scattered over almost entire surface, perhaps one-third as abundant as punctures; vestiture of stout bristles, moderately abundant, rather short.

Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; scutellar notch rather shallow, broad; basal margins each armed by 12-13 coarse, overlapping crenulations; striae slightly impressed, punctures rather coarse deep; interstriae slightly narrower than striae, rather weakly convex, punctures replaced by uniseriate rows of coarse, narrow crenulations. Declivity rather steep, convex; striae narrower and slightly deeper than on disc; all interstriae uniseriately tuberculate, tubercles small on 1, increasing in size laterally until very coarse on 9,9 slightly elevated, joining costal margin, elevation and tubercles continuing to apex without interruption. Vestiture consisting of uniseriate rows of pointed bristles, each about equal in length to distance between rows.

Female.-Similar to male except frons convex to narrow, transverse impression just above epistomal margin, a median fovea near center, granules not evident.

Distribution.-Kansas and Texas to Pennsylvania and South Carolina.
USA: Alabama, District of Columbia, Georgia, Illinois, Indiana, Iowa, Kansas, Louisiana, Maryland, Michigan, Mississippi, Missouri, New Jersey, New York, North Carolina, Ohio, Pennsylvania, South Carolina, Tennessee, Texas, Virginia, West Virginia. MEXICO: Guanajuato: Irapuato. Hopk. US1326 (introduced but not established).
Hosts.-Celtis occidentalis, Morus alba, M. rubra.

Biology. - Young adults emerge from the brood tree in the fall and construct maturation feeding hibernation tunnels in living host trees, primarily in the outer bark but extending to the outer area of phloem tissue. In some areas considerable damage results from this injury. In the spring the beetles emerge from hibernation and attack unthrifty, injured, or cut trees in any area from the stump to the branches. The monogamous beetles
construct transverse, biramous parental galleries that engrave both the wood and inner bark surfaces; the male initiates the attack and constructs the entrance tunnel. According to Blackman (1922:54), the two combined egg galleries of a biramous system varied from 3 to 5 cm in length; the number of egg niches varied from 30 to 90 . The larval mines parallel the grain of the wood, engraving both the wood and phloem tissues. Evidently there are two generations each year. Although red mulberry appears to be the preferred host, it is not uncommon in hackberry.

Notes. - The above treatment was based on my series from Lawrenceville, Illinois; in all 429 specimens were examined. One male syntype of granicollis was sent by Eichhoff to the U.S. National Museum. That specimen is here designated as the lectotype of granicollis Eichhoff and is consistent with what I treat here as frontalis, although I have not seen Olivier's type. A search for Olivier's type was unsuccessful, but it probably is in the Paris Museum. The male and female syntypes of Phloeophthorus moriperda were also compared directly to my material. Although the size of these syntypes is at the lower limits for this species, the other characters fall well within the range of its variability. It is quite apparent that the species was introduced into the mulberry (Morus alba) plantation at Irapuato, but my search gave no indication that it survived there. Cibrián (pers. comm.) apparently found it there at a later date. Because Hopkins did not designate a holotype for his species, I here designate his "female type" as the lectotype of Phloeophthorus moriperda.

## 14. Phloeotribus destructor Wood

Phloeotribus destructor Wood, 1969 Great Basin Nat. 29:123 (Holotype, male; Morelia, Michoacán, Mexico; Wood. Coll.)
Diagnosis.- This species is distinguished from frontalis (Olivier) by the absence of tubercles on declivital interstriae 1 to 4 , by the much more coarsely punctured pronotum, with the interspaces devoid of fine impressed points, and by the different host and distribution.

Male.- Length $1.8-2.4 \mathrm{~mm}, 2.1$ times as long as wide; color dark brown.

Frons shallowly, broadly concave from epistomal margin almost to level of upper
margin of eyes; lateral margins armed by a pair of moderately large, pointed tubercles at level of antennal insertion; surface shining, subreticulate below, almost rugulose above, marginal areas above tubercles with rather abundant, small, rounded granules; vestiture of rather abundant, coarse, short hair. Segment 1 of antennal club 2.6 times as wide as long.

Pronotum 0.81 times as long as wide; widest at base, sides rather weakly, arcuately converging to a feeble constriction just behind anterior margin, rather narrowly rounded in front; surface coarsely, very closely, rather shallowly punctured, a few granules and fine asperities in anterolateral areas, interspaces between punctures less than half as wide as diameter of a puncture, devoid of impressed points; vestiture of rather fine, moderately abundant, short hair.

Elytra 1.4 times as long as wide, 1.9 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; scutellar notch rather shallow, obtuse; basal margins each armed by 12-14 coarse, overlapping crenulations; striae moderately impressed, punctures deep, rather fine on basal fourth, becoming coarser toward declivity; interstriae as wide as striae, closely crenulate, crenulations confused, each about half as wide as an interstriae, low except at base and much larger at base of declivity. Declivity convex, moderately steep; striae narrowly impressed, punctures rather small; interstriae 1 to 8 equally convex, armed at base by crenulations that increase in size laterally, interstriae on declivital face not at all granulate, uniseriately, finely punctured, except 9 joining costal margin, its elevation and course tubercles continuing to apex. Vestiture of slender, interstrial bristles of uniform length, slightly confused on most of disc, becoming uniseriate toward and on declivity, on declivity each equal in length to distance between rows.

Female.- Similar to male except frons convex, a narrow, transverse impression immediately above epistoma, lateral tubercles absent.

Distribution.- Michoacán.
MEXICO: Michoacán: 19 km E Carapan, 18-Vl-65, wild cherry, No. 76, S. L. Wood; Morelia; 14-V1-65, peach, No. 57, S. L. Wood.

Hosts.- Prunus persica, P. sp.
Bıology.- This species was misidentified in the field as pruni, with which the Carapan series was intermixed; evidently their habits are very similar. The Morelia series was taken from an apparently healthy peach tree. Although some of the new attacks could very well have been for maturation feeding, at least one new, biramous gallery contained eggs. It is a potential horticultural pest species.

Notes.- The above treatment was based on the type series of 19 specimens.

## 15. Phloeotribus dentifrons (Blackman) Fig. 90

Phthorophloeus dentifrons Blackman, 1921, Mississippi Agric. Expt. Sta. Tech. Bull. 10:3 (Holotype, female: Agricultural College or Starkville, Mississippi; U.S. Nat. Mus., 56929)
Diagnosis.- This species is distinguished from texanus Schaeffer by the presence of granules on all declivital interstriae, by the less strongly impressed striae with smaller punctures, by the smaller granules on the discal interstriae, and by slightly smaller average size.

Male.- Length $1.2-1.6 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown.

Frons deeply concave from epistoma to upper level of eyes, lateral margins armed by a pair of rather large, pointed tubercles, margin subacute immediately above tubercles; surface reticulate, a few granules on upper margins; vestiture of sparse, fine, inconspicuous hair. Segment 1 of antennal club 2.5 times as wide as long.

Pronotum 0.85 times as long as wide; widest at base, sides weakly arcuate, converging slightly anteriorly, rather broadly rounded in front; surface subreticulate, punctures of moderate size and depth, usually not clearly defined, anterolateral area armed by about 15 asperities of varying sizes on each side; vestiture of moderately abundant, rather short, very stout setae.

Elytra 1.4 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; scutellar notch shallow, obtuse; basal margins each armed by 9 to 11 coarse crenulations; striae feebly if at all impressed, punctures rather small, deep;
interstriae as wide as striae, almost smooth, punctures replaced by rather small, rounded, uniseriate granules. Declivity convex, rather steep; striae distinctly impressed, punctures smaller, less distinct; interstriae weakly convex, granules very slightly larger on interstriae 1 to 9 . Vestiture consisting of very fine, short, strial hair, and uniseriate, interstrial rows of suberect, very stout, almost scalelike bristles; each bristle equal in length to twothirds of distance between rows.
Female.- Similar to male except frons convex, unarmed, a very weak, transverse impression immediately above epistoma.

Distribution. - North Dakota and Pennsylvania to Texas and Florida.
USA: District of Columbia, Florida, Illinois, Kansas, Louisiana, Maryland, Michigan, New Jersey, New Mexico, North Carolina, North Dakota, Pennsylvania, South Carolina, Texas, West Virginia.

Hosts.-Celtis occidentalis, Celtis sp., Condalis obtusifolia.

Biology.- The beetles attack weakened or injured limbs and branches of the host tree. They pass the winter as young adults in the brood tunnels. In the spring they emerge to attack a new host. Their method of attack and gallery patterns resemble frontalis. There are two generations each year.

Notes.- The above treatment was based on the holotype and on 539 other specimens.

## 16. Phloeotribus texanus Schaeffer

Phloootribus texanus Schaeffer, 1908, J. New York Ent. Soc. I6:222 (Lectotype, male; Esparza Ranch. Brownsville, Texas; U.S. Nat. Mus., 42488, present designation)
Diagnosis. - This species is distinguished from dentifrons (Blackman) by the odd-numbered, alternate, declivital interstriae being armed by pointed tubercles, the even-numbered interstriae being unarmed, by the more distinctly impressed discal striae, with the coarse punctures wider than the interstriae, by the wider, discal, interstrial granules, by the larger average size, and by the restricted distribution.

Male.- Length $1.5-1.9 \mathrm{~mm}, 2.0$ times as long as wide; color dark brown.

Frons as in dentifrons except excavation extending slightly above eyes. Antennal scape bearing a tuft of long, yellow hair; segment 1 of club 3.0 times as wide as long.

Pronotum 0.87 times as long as wide; widest a third of length from base, sides rather strongly arcuate, slightly constricted just behind anterior margin, narrowly rounded in front; surface reticulate, punctures moderately coarse, deep, slightly more than anterior half armed by granules and small asperities; vestiture of moderately abundant, short, very stout bristles.

Elytra 1.2 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; scutellar notch shallow, obtuse; basal margins each armed by eight coarse crenulations; striae distinctly impressed, punctures coarse deep; interstriae slightly narrower than striae except at base, almost smooth, with uniseriate rather coarse, rounded granules. Declivity convex, rather steep; striae impressed, punctures much smaller than on disc; interstriae convex, all uniseriately granulate, those on $3,5,7$, and 9 and sometimes 1 and 8 much larger and sharply pointed. Vestiture of uniseriate rows of suberect, very stout, interstrial bristles, each bristle about equal in length to distance between rows.

Female. - Similar to male except frons convex, a slight transverse impression just above epistoma, a median fovea at center; scape without tuft of hair.

Distribution. - Nuevo León and Texas to South Carolina and Florida.

USA: Florida: Biscayne, Lake Worth, Mariana. Louisiana: Creole, Killona. South Carolina: Charleston. Texas: Brownsville, Columbus, Devils River, Hidalgo Co., Southmost. MEXICO: Nuevo León: 24 km NW Montemorelos, 26-IV-69, D. E. Bright. DOUBTFUL ORIGIN: Intercepted at Mexican border in shelled corn, lot $36-22399,16-\mathrm{V}-36$. A specimen labeled Barro Colorado lsl., C. Z., Panama, VI 1942, Fomes sp., No. 498I, J. Zetek, at the U.S. National Museum, alnost certainly is mislabeled.

Hosts.-Celtis laevigata, Condalia obtusifolia.

Biology.- Evidently the habits are similar to dentifrons, with which it was intermixed in one series.

Notes. - The above treatment was based on 2 syntypes and on 563 additional specimens. Because Schaeffer did not designate a type for his species, I here designate the male syntype in the U.S. National Museum as the lectotype of texanus Schaeffer.

## 17. Phloeotribus scabricollis (Hopkins)

## Phloeophthorus scabricollis Hopkins, 1916, in Blatchley and Leng, Rhynchophora or Weevils of North Eastern America, p. 656 (Holotype, male; Hessville, Indiana; U.S. Nat. Mus., 7485)

Diagnosis.- This unique species is distinguished from other representatives of the genus by the deep, narrow striae, by the very short, abundant, confused elytral hair, by the distinctive pronotum, by the absence of frontal tubercles in the male, and by the host.

Male.- Length 2.0-2.3 mm, 2.0 times as long as wide; body color dark brown.

Frons shallowly concave, lateral margins subacutely elevated on lower two-thirds, but devoid of tubercles at level of antennal insertion; surface minutely rugose-reticulate, with a few minute punctures; vestiture hairlike, inconspicuous. Segment 1 of antennal club 4.0 times as wide as long.

Pronotum 0.83 times as long as wide; widest at base, sides weakly arcuate, converging very slightly, broadly rounded in front; surface closely, sharply punctured, interspaces about equal in width to one-half diameter of a puncture, becoming granulate to finely asperate anteriorly and laterally, three coarse asperities at anterolateral margin; vestiture rather short, abundant, hairlike.
Elytra 1.3 times as long as wide, 1.9 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, broadly rounded behind; scutellar notch shallow, obtuse; basal margins each armed by 15 coarse crenulations; striae narrowly, rather strongly impressed, punctures rather small, deep; interstriae about one and one-half times as wide as striae, tubercles close, confused, larger ones in somewhat irregular, uniseriate rows. Declivity convex, moderately steep; striae about as on disc; interstriae equally convex, $3,5,7$, and 9 each bearing a uniseriate row of fine, pointed tubercles, tubercles evidently larger laterally. Vestiture consisting of uniformly short, abundant, confused, hairlike bristles on disc and declivity, each bristle equal in length to little more than half width of an interstriae.
Female.- Similar to male except frons convex; asperities of pronotum slightly larger and more widely distributed; all declivital interstriae bearing at least a few minute tubercles.

Distribution.- Illinois to Ohio.
USA: 1llinois: Lyons, 20 -VIII-12, G. M. Greene; Lisle, DuPage Co., 8 -V11-70, Ptelea trifoliata, J. Appleby. Indiana: Hessville, 14-VII, W. S. Blatchley; Indiana Dunes St. Pk. Ohio: Georgesville, $10-1 \mathrm{X}-98$, boring in axils of leaves of Staphylea trifolia.

Hosts.-Ptelea trifoliata, Staphylea trifolia.

Biology. - Specimens were taken from small, unthrifty branches. The egg galleries were transverse.

Notes.- The above treatment is based on the holotype and on 19 other specimens.

## 18. Phloeotribus scabratus Blandford

Phloeotribus scabratus Blandford, 1897. Biol. Centr. Amer., Coleopt. $4(6): 164$ (Lectotype, male; Volcán de Chiriquí; British Mus. Nat. Hist., present designation)
Diagnosis.- The above key places this species near scabricollis Hopkins, although they are not closely related. Among Central American species it is unique in having the pronotal sculpture coarse and in having the elytral vestiture scalelike and confused on the disc but in uniseriate rows on the declivity.

Male.- Length 2.5 mm , about 1.8 times as long as wide; color dark brown.

Frons broadly concave from epistoma to upper level of eyes; lateral margins moderately elevated, unarmed; details of surface sculpture largely obscured by debris, evidently rugose-reticulate, ornamented by a few coarse bristles. Antennal scape bearing a small tuft of long, dark hair; segment 1 of club at least five times as wide as long.

Pronotum 0.76 times as long as wide; widest on basal third, sides moderately arcuate, not converging on basal half, distinctly constricted before rather narrowly rounded anterior margin; surface shining, irregularly, very closely, rather coarsely punctured, anterior or lateral margins of punctures weakly to subasperately elevated, interspaces marked by minute points; anterolateral areas rather finely asperate, a low, completely marginal row across anterior margin; vestiture of stout, semirecumbent bristles of moderate length.

Elytra 1.1 times as long as wide, 1.6 times as long as pronotum; basal margins each armed by 14 crenulations; scutellar notch rather broad, shallow; sides almost straight and parallel on slightly more than basal half, broadly rounded behind; striae rather
strongly impressed, punctures rather coarse, deep; interstriae wider than striae, with numerous, short, confused, acute, setiferous crenulations. Declivity convex, rather steep; interstriae equally convex, 1 very slightly higher, each uniseriately tuberculate, except largely confused on 1. Vestiture of suberect scales, each scale rather short, about four to six times as long as wide, very slightly shorter and stouter on declivity.
Distribution. - Panama.
PaNAMA: Volcán de Chiriquí. Chiriquí, 4000-6000 ft, G. C. Champion.

Notes.- This species was described from two male syntypes. The first of these specimens has been considered to be the type; it is here designated as the lectotype of scabratus Blandford.

## 19. Phloeotribus opimus Wood

Phloeotribus opimus Wood, 1969, Brigham Young University Sci. Bull., Biol. Ser. 10(2):7 (Holotype, male; Zomorano, Morazán, Honduras; Wood Coll.)
Diagnosis. - This species is allied to demessus Blandford, but it may be distinguished by the smooth, shining, discal interstriae, except for the granules, by the almost straight basal margin of the pronotum, and by the slightly smaller average size.

Male.- Length $1.4-1.9 \mathrm{~mm}, 1.8$ times as long as wide; color very dark brown, with light vestiture.
Frons deeply excavated from upper level of eyes to epistoma, deepest near center, lateral margins acute from middle to antennal bases, surface rather coarsely reticulate; vestiture largely confined to marginal areas.

Antennal scape long, ornamented by a tuft of long yellowish hair. Segment 1 of antennal club three times as wide as long.

Pronotum 0.8 times as long as wide; widest one-third length from base, sides rather strongly arcuate, anterior constriction weak, rather broadly rounded in front; surface coarsely, deeply punctured, spaces between punctures almost smooth, subshining, less than half width of a puncture, with a small rounded, setiferous granule on anterior margin of each puncture; vestiture consisting of short, stout, whitish bristles.

Elytra 1.1 times as long as wide, 1.5 times as long as pronotum; sides straight and
parallel on basal two-thirds, broadly rounded behind; scutellar notch shallow, obtuse; single row of 9-11 crenulations on each elytral base high, coarse; striae slightly impressed, punctures coarse, deep; interstriae convex, narrower than striae, armed by a row of small setiferous tubercles. Declivity steep, convex; striae somewhat narrower and deeper; interstriae 9 weakly elevated, more coarsely serrate. Vestiture consisting of uniseriate rows of suberect flattened bristles, each bristle separated within a row by distances equal to its own length, and from those in adjacent rows by one and one-half times its own length.

Female. - Similar to male except frons convex, lateral margins rounded; antennal scape without tuft of hair.

Distribution. - Jalisco to Costa Rica.
Mexico: Jalisco: 33 km N Juchitlan, 3 -V1I-65, Ficus. $1300 \mathrm{~m}, \mathrm{~S}$. L. Wood. GUatenala: Palín. Esquintla, 19-V-64, Ficus, 300 m . S. L. Wood. HONDURAS: Zamorano, Morazán, 18-JV-64, 700 m , No. 558. Ficus. No. 506. Celtis iguanae, No. 507. Seriania triquetra, S. L. Wood. COSTA RICA: Lower Río Tempisque. Guanacaste, $25-\mathrm{III}-64.15 \mathrm{~m}$. No. 501, Ficus, S. L. Wood.

Hosts. - Ficus spp., less commonly (accidentally?) in Celtis iguanae and Serjania triquetra.
Biology. - The twigs and small branches of living fig trees are most commonly selected, although this species will attack broken branches. They tend to select those branches that have started to die near their terminal ends and rear their broods at the margin of the vigorous living tissues. In attacks of this type only one or two monogamous pairs of beetles were found in each branchlet. Presumably several overlapping generations are produced each year.

Notes.- The above treatment was based on the type series of 103 specimens.

## 20. Phloeotribus demessus Blandford

Phloeotribus demessus Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):165 (Lectotype, female; Toxpam or Tuxpan, Mexico; British Mus. Nat. Hist., present designation)
Phloeotribus tuberculatus Eggers, 1951, Ent Blätt. 45-46: 147 (Holotype, female; Turrialba, Cartago, Costa Rica, U.S. Nat. Mus., 69631): Wood, 1973, Great Basin Nat. 33:181. Synonymy
Phloeotribus eggersi Schedl, 1962. Beitr. Ent. 12:487. Replacement name

Diagnosıs.- This species is allied to opimus Wood, but it may be distinguished by the presence of numerous impressed points toward the base of the discal interstriae, these points becoming granulate posteriorly; by the posteriorly extended posteromedian area of the pronotum; and by the larger average size.

Male.-- Length $1.6-2.3 \mathrm{~mm}, 1.8$ times as long as wide; color very dark brown.

Frons shallowly concave from epistoma almost to upper level of eyes, lateral margins at level of antennal insertions moderately elevated but unarmed; surface strongly reticulate, punctures small, moderately abundant, obscure; vestiture of rather abundant bristles of moderate length. Antennal scape ornamented by a small tuft of hair; segment 1 of club about five times as wide as long.

Pronotum 0.87 times as long as wide; widest a third of length from base, sides rather strongly arcuate, very slightly constricted just before narrowly rounded anterior margin; basal margin obtusely produced posteriorly in median area; surface subshining, punctures deep, coarse and moderately large intermixed, with interspaces rather densely marked by very small, deep punctures; vestiture sparse, of short, very stout bristles.

Elytra 1.1 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal half, broadly rounded behind; scutellar notch very broad; basal margins each armed by 15 broadly overlapping, rather low crenulations, a less definite submarginal row also indicated; striae rather strongly impressed at least toward declivity, punctures rather large, deep; interstriae slightly wider than striae, uniseriately, closely crenulate, cremulations more than half as wide as an interstriae, intervening spaces marked by rather abundant, deep, fine punctures. Declivity convex, steep; striae and interstriae slightly narrower than on dise, crenulations narrower, more pointed, often slightly higher. Vestiture consisting of uniseriate rows of suberect, flattened, almost scalelike, interstrial bristles of equal length on disc and declivity; each bristle about equal in length to two-thirds distance between rows, spaced within rows by less than length of a bristle.

Female.- Similar to male except frons convex, punctures much larger, very shallow; tuft of hair on scape almost entirely absent.

## Distribution.- Veracruz to Panama.

MEXICO: Veracruz: Jicaltepec, Toxpam (or Tuxpan),
Sallé. COSTA RICA: Turrialba, Cartago, 9-III-64, 700 m, No. 439, unidentified tree; Río Damitas, Dota Mountains, San José, 18-II-64, 250 m, No. 432, stump; Finca Gromaco on Río Coto Brus, Puntarenas, 14-VII-63, 500 m , No. 84, log. PANAMA: Barro Colorado lsland, Canal Zone, 27-X11-63, 70 m . No. 346, tree branch, all by S. L. Wood.

Biology.- This species made typical biramous, transverse parental galleries; larval mines paralleled the grain of the wood.

Notes.- The five syntypes of demessus and 58 other specimens were used in preparing the above treatment. Because this species was based on a syntypic series of five specimens, the second specimen, a female from Mexico labeled and previously considered to be the type, is here designated as the lectotype of demessus Blandford. The holotype of tuberculatus was also examined.

## 21. Phloeotribus armatus Blandford

Phloeotribus armatus Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):166 (Holotype, male; Volcán de Chiriquí, Panama; British Mus. Nat. Hist.)
Phlocotribus mixtecus Bright, 1972, Canadian Ent. 104:1494 (Holotype, female; 26 miles S Juchatengo. Oaxaca, Mexico; Canadian Nat. Coll., 12609); Wood. 1973, Great Basin Nat. 33:181. Synonymy
Diagnosis.- This species is distinguished from setulosus Eichhoff by the slightly elevated, dentate, declivital interstriae 1 and 3, 2 and 4 being unarmed except at base, and by the distribution.

Male.- Length $1.9-2.4 \mathrm{~mm}, 1.8$ times as long as wide; color very dark reddish brown.

Head and pronotum as in setulosus, except base of pronotum almost straight.

Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; outline as in setulosus, scutellar notch not as deep, more obtuse, basal armature similar; striae strongly impressed, punctures coarse, deep, partly confluent; interstriae as wide as striae, uniseriately crenulate, each crenulation almost as wide as interstriae and evidently coarser than in setulosus, general surface with numerous impressed points. Declivity steep, convex; striae and interstriae slightly narrower than on disc; interstriae $1,3,5$, and 7 slightly more strongly
convex and tuberculate, two or three of tubercles on 3,5, and 7 larger than others, 2, 4, and 6 unarmed except at extreme base; interstriae 9 very strongly, narrowly elevated, much stronger than setulosus, and coarsely serrate, continuing to apex. Vestiture largely abraded on disc; consisting of uniseriate interstrial rows of erect bristles of equal length throughout, each bristle equal in length to distance between rows, somewhat similarly spaced within each row; bristles absent on even-numbered declivital interstriae on at least lower half.

Female. - Similar to male except frons as in female setulosus.

Distribution. - Oaxaca to Colombia.
MEXICO: Oaxaca: 115 miles or 184 km S Oaxaca, 27-30-V-71, D. E. Bright. GUatemala: San Miguel Duenas, 29-V-66, J. M. Campbell. HONDURAS: 1940, W. von Hagen. PANAMA: Fort Clayton, Canal Zone, $22-\mathrm{Xll}-63,50 \mathrm{~m}, \mathrm{No} .325, \log , \mathrm{~S}$. L. Wood; Cerro Punta, Chiriquí, 18-24-VII-61, J. M. Campbell; Darien, 6-11-VIl-61; Limón Bay, Canal Zone, $30-\mathrm{XII}-63,5 \mathrm{~m}$, No.
353, tree limb.

Biology.- The biramous parental galleries evidently are diagonal and engrave the wood rather deeply. The true character of the galleries was not clear.
Notes.- The above treatment was based on the type of armatus and on 149 other specimens.

## 22. Phloeotribus biguttatus Blandford

Phloeotribus biguttatus Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6): 169 (Holotype, male; Bugaba, Chiriqui, Panama; British Mus. Nat. Hist.)
Diagnosis. - This species is distinguished from setulosus Eichhoff by the broad, short pronotum having the asperities restricted to the anterior fourth, with the anterior margin very coarsely serrate; by the smaller discal, interstrial tubercles; and by the less strongly elevated declivital interstriae 9 .

Male. - Length 2.0-2.5 mm, 1.73 times as long as wide; dark brown, slightly reddish posteriorly.

Frons and antenna as in setulosus except frontal impression extending very slightly above upper level of eyes, and epistomal carina less strongly procurved.

Pronotum 0.75 times as long as wide; widest at extreme base, sides convergently arcuate from base to rather narrowly rounded anterior margin; anterior margin armed by
two very course, close median teeth, two pairs of submarginal teeth of decreasing size lateral to these; surface as in setulosus, with numerous minute points and moderately large, shallow punctures, punctures distinctly smaller than in setulosus; asperities small, less than a dozen, restricted to anterior fourth on median area; vestiture consisting of a few bristles near anterior margin.
Elytra 1.1 times as long as wide, 1.5 times as long as pronotum; as in setulosus except discal interstrial crenulations smaller, appearing more widely spaced, and declivital interstriae 9 lower, about two-thirds as strongly elevated.

Female.-Similar to male except frons convex, scape without tuft of hair; anterior margin of pronotum with serrations reduced, usually absent in median area.

Distribution.- Panama to Colombia and Venezuela.
PANAMA: Chiriquí: Bugaba, G. C. Champion. OTHER COUNTRIES: Colombia, Venezuela.

Host.- Brosimum sp.
Biology.- Specimens were taken from transverse galleries in broken limbs.

Notes.- The above treatment was based on the male holotype and on 86 other specimens. Three specimens from Panama in the British Museum were assigned to this species but were not mentioned by Blandford.

## 23. Phloeotribus subovatus Blandford

Phloeotribus subocatus Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):167 (Lectotype, male; El Reposo, Guatemala; British Mus. Nat. Hist., present designation)
Diagnosis. - This species is distinguished from setulosus Eichhoff by characters mentioned in the above key, by the stouter body, by the narrower interstrial tubercles, and by the stouter interstrial setae.

Male.- Length 2.0-2.5 mm, 1.7 times as long as wide; color almost black.

Frons as in setulosus except narrower and more pubescent; epistomal transverse carina straight, very strongly elevated, about onefourth as wide as epistoma, carina about half as high as wide. Antenna as in setulosus.

Pronotum similar to setulosus except asperities averaging larger, those on anterolateral margin more consistently present; discal area reticulate, punctures usually not as deep.

Elytra with striae impressed, punctures rather small; interstriae twice as wide as striae, most crenulations half as wide as an interstriae, spaced as in setulosus but averaging smaller; interstrial setae slightly shorter and stouter than in setulosus. Declivity similar to setulosus except interstriae three times as wide as striae, 9 moderately elevated and serrate to striae 3 .

Female. - Similar to male except sexual differences as in setulosus.

Distribution.- Guatemala to Venezuela.
guatemala: El Reposo, 800 ft , Champion. BritISH HONDURAS: Blancaneaux. VENEZUELA: 20 km SW El Vigía, Merida, 21-Xl-69, 50 m, No. 147, tree limb, S. L. Wood.

Brology.- Specimens were taken from biramous, transverse tunnels in a large limb. The inner bark of the host had a distinct yellow color.

Notes. - From Blandford's syntypic series of 12 specimens from El Reposo, Guatemala, I here designate a male on a double mount (with a female) as the lectotype of subovatus. The above treatment was based on Blandford's material and on 127 other specimens from Venezuela.

## 24. Phloeotribus setulosus Eichhoff Fig. 16

Phlocotribus setulosus Eichhoff, 1868, Berliner Ent. Zeitschr. 12:149 (Lectotype, male; Colombia, not Carolina as published: Brussels Mus.)
Phlocotribus rudis Eichhoff. 1868, Berliner Ent. Zeitschr. 12:149 (Syntypes? male; Brazil; lost with Hamburg Mus.): Wood, 1974, Great Basin Nat. 34:286. Synonymy
Phloeotribus dubius Eichhoff, 1868, Berliner Ent. Zeitschr. 12:150 (Holotype?; male; Colombia: Berlin Mus.); Wood, 1977, Great Basin Nat. 37:209. Synonymy
Phloeotribus asperatus Blandford, 1897. Biol. Centr. Amer., Coleopt. 4(6):166 (Holotype, male, Panajachel, Guatemala; British Mus. Nat. Hist.): Wood, 1973, Great Basin Nat. 33:182. Synonymy Phloeotribus sodalis Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6): 168 (Lectotype, male: Cerro Zunil, Guatemala; British Mus. Nat. Hist., designated by Wood, 1974, Great Basin Nat. 34:286). Synomymy
Phlocotribus spinipemis Eggers, 1931, Ent. Blätt. 26:168 (Holotype, male; Colombia, Moritz; Berlin Mus.): Wood, 1977, Great Basin Nat. 37:209. Synonymy Phloeotribus bolivianus Eggers, 1933, Trav. Lab. d'Ent. Mus. Nat. d'Hist. Nat. Paris, Mem. 1:5 (Holotype, male; Cochabamba, Bolivia: U.S. Nat. Mus., 60862); Wood, 1974, Great Basin Nat. 34:286. Synonymy

Diagnosis.- This species is distinguished from armatus Blandford by the equally convex, equally tuberculate declivital interstriae 1 to 8 and by the somewhat less strongly elevated declivital interstriae 9.

Male.- Length $1.9-2.4 \mathrm{~mm}, 1.8$ times as long as wide; color very dark reddish brown.

Frons somewhat irregularly concave from epistoma ahmost to upper level of eyes, lateral margins moderately elevated at level of antennal bases, unarmed by tubercles, a slight callus in median area at this level except for narrow, impressed, median line, epistomal margin elevated on median half as a procurved, transverse carina, a premandibular lobe developed below this elevation; surface reticulate, very finely punctured; vestiture sparse, of fine, inconspicuous hair. Antennal scape bearing a conspicuous tuft of long, yellow hair; segment 1 of club more than seven times as wide as long.

Pronotum 0.82 times as long as wide; posterior margin slightly extended posteriorly in median area, widest a third of length from base, sides strongly arcuate to feeble constriction just before rather narrowly rounded anterior margin; surface rather coarsely but not closely asperate on anterior half, coarsely, irregularly punctured behind, also extending into asperate area, width of interspaces averaging less than half as wide as punctures, rather densely marked by deep, impressed points, vestiture consisting of a few stout bristles in marginal areas.

Elytra 1.1 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal half, rather broadly rounded behind; scutellar notch shallow, obtuse; basal margins each armed by 11 overlapping, basally fused crenulations; striae rather strongly impressed, punctures coarse, deep; interstriae convex, as wide as striae, uniseriately crenulate, each crenulation at least half as wide as interstriae, general surface shining and marked by numerous impressed points. Declivity steep, convex; striae and interstriae slightly narrower than on disc, interstriae 1 to 8 uniseriately, rather finely tuberculate, 1 feebly elevated, 9 rather strongly elevated and serrate to apex, joining costal margin just before apex. Vestiture usually abraded on disc, consisting of uniseriate, interstrial rows of rather stout bristles of equal length
throughout, each bristle equal in length to about three-fourths of distance between rows, somewhat similarly spaced within each row.

Female.- Similar to male except frons slightly convex, with a rather large, median callus at level of antennal insertion, a weak, transverse impression just above the weakly elevated epistomal margin, punctures larger, shallow.
Distribution.-Veracruz to Peru and Brazil.

MEXICO: Chiapas: Simohovel. Veracruz: Lago Catemaco, Tampico. GUatemala: Cerro Zunil, Panajachel, Rodeo. HONDURAS: Zamorano. COSTA RICA: Dominical, Moravia, Playón, Puerto Viejo, Rio Damitas in the Dota Mts., Río Tempisque, San Isidro de Coronado, San José. PANAMA: Boquette, Bugaba, La Chorrera. OTHER COUNTRIES: Brazil, Colombia, Peru. Venezuela.

Hosts.- Brosimum sp., Cedrela mexicana, Celtis iguanae, Croton gossypiifolius, Ficus sp., and at least two additional tree species.

Biology.- This common species occurred most frequently in limbs and branches larger than 2 cm in diameter, but it also attacked logs and stumps. The gallery system was typically transversely biramous with the larval mines following the grain of the wood. Several overlapping generations appeared to occur each year in Costa Rica.

Notes. - The above treatment was based on the male holotype of asperatus and the male lectotypes of setulosus and sodalis, and on 458 additional specimens. The surface sculpture of the pronotum and the elytral disc varies slightly within series. This fact, coupled with the paucity of specimens, has led to the redescription of this species. At least part of Blandford's armatus also belongs to this species. Because sodalis was based on a syntypic series, the first specimen, a male from Cerro Zunil previously labeled and considered to be the type, is here designated as the lectotype of sodalis Blandford.

Two specimens of rudis in the Chapuis Collection that were identified by Eichhoff are of this species. These specimens could be cotypes.

## 25. Phloeotribus maurus Wood

 Phlocotribus maurus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):6 (Holotype, male; Rincón de Osa, Guanacaste. Costa Rica; Wood Coll.)Diagnosis.- Within the Central American fauna this species is allied to furvus Wood, although it is not closely related; it may be distinguished by the uniseriately crenulate interstriae, by the uniseriate, interstrial bristles, and apparently by the smaller average size.

Male.-Length $2.4-3.1 \mathrm{~mm}, 1.7$ times as long as wide; color very dark brown to black.

Frons similar to but much narrower than in furvus; sculpture similar; vestiture above antennal bases much coarser than in furvus. Scape bearing a rather large, dense tuft of dark hair.

Pronotum outline as in furvus; surface less uniformly, more deeply punctured, some punctures toward base much larger than in furcus; anterolateral asperities about twice as large as in furvus, vestiture at lateral margins coarser and longer.

Elytra 1.03 times as long as wide, 1.2 times as long as pronotum; sides weakly arcuate from base to declivity, somewhat narrowly rounded behind; scutellar notch abrupt, broad, very deep, matching extension of pronotum; basal margins armed by 12 or more low, overlapping crenulations; striae strongly impressed, punctures clearly indicated; interstriae distinctly less than twice as wide as striae, punctures subcrenulate on 2 and 3 to declivity, less distinctly so on 4 to 6 , crenulations uniseriate except somewhat biseriate at base of 2 , some of them as wide as an interstriae; interstriae narrower and more convex toward declivity. Declivity convex, moderately steep; interstriae narrower than on disc, each with a median, subserrate row of low tubercles. Vestiture consisting of a row of short, suberect bristles on each interstriae; each bristle not longer than a third distance, between rows; largely abraded on basal half; some fine hair also on sutural interstriae.

Female.-Similar to male except frons convex, foveate just above level of antennal insertion; tuft of hair on scape absent.

Distribution. - Veracruz to Costa Rica.
MEXICO: Veracruz: Lago Catemaco, 1-3-V-69, D. E. Bright. COSTA RICA: Rincón de Osa, Puntarenas, 11 -VII-66, 30 m , No. 63, Ficus, S. L. Wood.

Host.-Ficus sp.
Biology.- The type series was taken from irregularly diagonal to almost longitudinal, biramous tunnels that rather deeply engraved the wood. The beetles were just beginning their galleries and very few eggs had been deposited.

Notes.- The above treatment was based on the type series of 32 specimens.

## 26. Phloeotribus pilula Erichson Fig. 91

Phloeotribus pilula Erichson, 1847, Archiv Naturgesch. 13(1): 138 (Lectotype, male; Peru; Zool. Mus. Berlin, designated by Wood, 1973, Great Basin Nat. 33:181)
Phloeotribus obliquus Chapuis, 1869, Synopsis des Scolytides, p. 45 (Syntypes; Mexique, Nouvelle-Grenada; Brussels Mus.); Wood, 1973, Great Basin Nat. 33:181. Synonymy
Phloeotribus obesus Kirsch, 1875, Deutsche Ent. Zeitschr. 19:283 (Holotype, sex? Peru; Dresden Mus.); Eggers, 1929. Wiener Ent. Zeit. 46:52. Synonymy
Phloeotribus manni Blackman, 1943, Proc. U.S. Nat. Mus. 94:385 (Holotype, female, Río Madeira, Brazil; U.S. Nat. Mus.); Wood, 1973, Great Basin Nat. 33:181. Synonymy
Phloeotribus australis Schedi, 1953, Mem. Queensland Mus. 13:80 (Holotype, male; Queensland, Australia; Schedl Coll.); Wood, 1977. Great Basin Nat. 37: 209. Synonymy

Fig. 91. Phloeotribus pilula, male. (After Schedl 1953:80.)

Diagnosis.- This species is distinguished from furvus Wood by the rugose-reticulate pronotal and elytral surfaces, by the uniseriate setae on discal interstriae $3-10$, and by the finer interstrial tubercles on the declivity.

Male.- Length $2.6-3.3 \mathrm{~mm}, 1.6$ times as long as wide; color almost black.

As in furvus except as noted in above diagnosis.

Female.- Similar to male except sexual differences as in furvus.

Distribution.-Chiapas to Peru and Brazil.

MEXICO: Chiapas: Palenque Ruins, 9-V-69, D. E. Bright. Other COUNTRIES: Brazil, Colombia, Peru, Venezuela

## Host.-Brosimum sp.

Brology.- Transverse, biramous galleries are made in the bole, limbs, and larger branches. It is a very common and widely distributed species.

Notes. - The above treatment was based on the lectotype of pilula, on the holotypes of manni and australis, on a syntype of $o b$ liquus, and on 108 other specimens.

## 27. Phloeotribus furvus Wood

Phloeotribus sulcifrons: Blandford, 1897 (nec. Chapuis, 1869), Biol. Centr. Amer., Coleopt. 4(6): 165

Phlocotribus furrus Wood, 1969, Great Basin Nat. 29:124 (Holotype, male; Turrialba, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- This species is allied to maurus Wood, but it is not closely related; it may be distinguished by the much more numerous, three-ranked discal, interstrial crenulations, by the confused, minute, interstrial setae, and, apparently, by the larger than average size.

Male.- Length $2.8-3.3 \mathrm{~mm}, 1.6$ times as long as wide; color black.

Frons broadly, shallowly, subconcavely impressed from epistoma to upper level of eyes, lateral margins weakly elevated, except more strongly raised at level of antennal insertions, unarmed, a low, transverse callus at level of antennal insertions; surface strongly reticulate, with rather close, shallow punctures of moderately small size. Antennal scape with a small tuft of rather short hair; segment 1 of club more than eight times as wide as long.

Pronotum 0.80 times as long as wide; basal margin obtusely extended posteriorly with
median fourth more acutely extended; widest just in front of posterolateral angles, rather strongly, arcuately convergent, weakly constricted just before rather narrowly rounded anterior margin; surface very densely, rather coarsely punctured, becoming somewhat granulate on anterior third; anterolateral angles with two or three coarse asperities, a row of small asperities extending along anterior margin to opposite side; vestiture of minute, dark setae at least in lateral areas.

Elytra 1.03 times as long as wide, 1.4 times as long as pronotum; sides weakly arcuate to base of declivity, rather broadly rounded behind; scutellar notch abrupt, deep, broad; basal margins armed by 19 low, overlapping crenulations; striae abruptly, narrowly deeply impressed, punctures small, deep; interstriae twice as wide as striae, dense crenulations narrow, rather high, often obscurely threeranked, general surface evidently minutely punctured. Declivity convex, steep; interstriae as on disc but slightly narrower, median tubercles larger, others largely absent, 9
moderately elevated from middle of declivity anteriorly. Vestiture of minute, abundant, confused hairlike bristles, each about equal in length to one-third width of an interstriae.

Female.-Similar to male except frons convex, with an indistinct central fovea, punctures larger, very shallow, antennal scape not ornamented by hair; interstriae 9 less strongly elevated.

Distribution.-Guatemala to Panama.
GUatemala: Las Mercedes, Quezaltenango, G. C. Champion. COSTA RICA: Turrialba, Cartago, 9-III-64, 700 m, No. 459 , unidentified trees, S. L. Wood: San Isidro del General. 5 -XII-63, 1000 m , No. 286, in flight, S. L. Wood. PANAMA: Bugaba, Chiriquí, G. C. Champion.

Biology.- This monogamous species constructed irregularly diagonal, biramous tunnels in a limb about 15 cm in diameter at Turrialba.

Notes. - The above treatment was based largely on the type series; all of Blandford's specimens were also studied. In all 131 specimens were examined.

## Tribe PHLOEOSININI

Phloeosinides Nüsslin, 1912, Zeitschr. Forst- und Landwirtsch. 1912:273 (Type-genus: Phloeosinus Chapuis, 1869)

Anatomical features.- The frons is usually sexually dimorphic, with the male frons impressed, the female flat to convex, the eye varied from entire to emarginate to completely divided (some Indo-Australian Phloeosinus), the antennal funicle is 5- to 7segmented, the club is flattened, slightly to strongly asymmetrical and with or without sutures, the pronotum is unarmed, the third tarsal segments are stout and bilobed (except slender in Chramesus), the scutellum is visible, and the metanotum is fused to the postnotum.

Biological features.- All American species are monogamous (a few Indo-Australian Phloeosinus are polygamous); all except Dendrosinus and a few Chramesus are phloeophagous. Parental tunnels are monoramous with a.conspicuous turning niche or nuptial chamber; some Dendrosinus tunnels are biramous (inconsistent). In the xylophagous Dendrosinus and Chramesus tunnels, fungal alteration of the wood is obvious, although symbionts have not been reported. Eggs are deposited in niches. Larval mines tend to follow a definite course and rarely cross one another.

Taxonomy.- This tribe consists of a diverse assemblage of distantly related genera that appear to be relics of a former much larger group. Allied genera are largely worldwide in distribution, with a slight concentration in Africa. Cladoctonus occurs in both Africa and South America, Dendrosinus is mostly in South America, Carphotoreus is known only from Central America, but allied genera are in Africa, and Phloeosinus is largely restricted to the northern hemisphere. Chramesus occurs only in America, but allied genera occur in Africa; future investigation may require the transfer of this genus to the Hypoborini. The North and Central American genera in this tribe are quite easily
recognized; the genera might be recognized with greater difficulty in other parts of the world.

## Genus DEndrosinus Chapuis

Dendrosinus Chapuis, 1869, Synopsis des Scolytides, p. 28 (Type-species: Hylesinus globosus Eichhoff, monobasic)
Diagnosis.- This small, distinctive, neotropical genus is not closely allied to any other genus in North or Central America.

Description.- Length $3.3-4.3 \mathrm{~mm}$, 1.5-1.6 times as long as wide. Frons flattened or weakly convex, variously ornamented by hair; male frons a little more strongly impressed than female. Eye elongate-oval, entire (broadly emarginate in one South American species). Antennal scape short, not reaching posterior margin of eye; funicle 7 segmented; club almost symmetrical, flattened, three procurved sutures on basal half. Pronotum unarmed (conspicuous anterolateral teeth occur in vittifrons Blandford; they are rudimentary in transversalis Blandford), punctate; grooved behind for reception of elytral bases. Scutellum small, rounded; appearing posteriorly displaced. Crenulations on elytral bases in a single row, not well developed; striae very narrow, deeply impressed; declivity convex, gradual, unarmed; abdomen ascending posteriorly to meet elytra. Coxae very widely separated; prothoracic precoxal ridge not well developed, but present. Third tarsal segments bilobed.
Distribution.- Eight neotropical species occur from Florida to Argentina.
Biology.- The two species treated here attack woody plants about $3-10 \mathrm{~cm}$ in diameter, where they construct transverse, biramous, parental galleries that extend well into the wood. The larvae are also xylophagous. In globosus (Eichhoff) the eggs are
placed in definite, randomly placed niches on all walls of the egg gallery. The larval mines
are rather long and wander aimlessly through the wood.

## Key to the Species of Dendrosinus

1. Antennal club slender, conspicuously longer than wide; frons shining, glabrous except ornamented by long hair on lateral margins and on epistomal area; pronotum rather coarsely, deeply punctured: elytral interstriae with small, confused granules; Florida to Puerto Rico; $3.5-4.3 \mathrm{~mm}$ $\qquad$ 1. bourreriae Schwarz

- Antennal club broad, much wider than long; frons closely, uniformly covered by short, golden pubescence; pronotum and elytral interstriae minutely granulate, punctures and tubercles not evident: Veracruz to Costa Rica; 3.3-4.0 mm

## 2. transversalis Blandford

## 1. Dendrosinus bourreriae Schwarz

 Figs. 92, 93Dendrosinus bourreriae Schwarz, 1920, Proc. Ent. Soc. Washington 22:225 (Holotype, sex?; Marathon, Key Vaca, Florida; U.S. Nat. Mus.)
Dendrosinus lima Eggers, 1930, Ent. Blätt. 26:166 (Holotype, sex? Puerto Rico; Berlin Zool. Mus.); Eggers, 1934, Ent Nachrbl. s:27. Synonymy
Diagnosis. - This species is easily distinguished by characters summarized in the above key.

Female.- Length $3.5-4.3 \mathrm{~mm}, 1.6$ times as long as wide; color black.

Frons broadly flattened from just above slightly elevated epistoma to vertex; a narrow epistomal lobe present; surface smooth, polished, shining on middle half, rather coarsely, closely punctured on upper fourth, on lower fourth, and on lateral margins; vestiture hairlike, moderately short, yellow on epistomal area and lower half of sides, upper lateral areas bearing a single row of about 20 dark, long hairs lying against frons, curling to median line, then ventrad, ending at base of lower setae of its origin. Eye entire.

Pronotum 0.84 times as long as wide; widest at posterolateral angles at middle of total length, sides strongly, arcuately converging to broadly rounded anterior margin: posteromedian area angulately extended behind, posterolateral margins grooved for reception of elytral bases; anterolateral areas unarmed; surface dull, with close, rather coarse, shallow punctures; vestiture of fine, very short, rather abundant, dark hair.

Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; widest on basal third, arcuately converging toward narrowly rounded, emarginate posterior margin, apex
of abdomen usually filling elytral notch; elytral bases extended anteriorly, very strongly so at humeral angles, scutellar notch appearing very strongly displaced posteriorly; crenulations on anterior margins rather small, distinct; striae narrowly, abruptly, rather deeply impressed, punctures fine, rather obscure; interstriae three to four times as wide as striae, almost flat, dull, armed by numerous narrow, rather small, confused, subcrenulate tubercles, each about a fifth as wide as interstriae, becoming rather coarsely crenulate toward base. Declivity convex, gradual, short, abdomen rising to meet elytra; interstriae narrower than on disc. Vestiture consisting of small recumbent, black hair, one hair arising from each granule; each hair equal in length to about half width of an interstriae.

Male.-Similar to female except lower frons very feebly impressed.

Distribution.- The Florida Keys to Puerto Rico and Jamaica.

USA: Florida: Key Largo, 13-V-39, D. J. and J. N. Knull: Marathon, Key Vaca, 7 -1I1-19, Bourreria havanensis. H. S. Barber and E. A. Schwarz, and 29-VI-5I, Eugenia buxifolia, Torrubia longifolia, S. L. Wood. PUERTO RICO: "Puerto Rico." JAMAICA: Duncans, 15-VIII-66, H. F. Howden and E. C. Becker.

Hosts. - Bourreria havanensis, Eugenia buxifolia, Torrubia longifolia.

Biology.- Specimens were taken at the type locality by Hubbard and Schwarz and by myself from host material $5-15 \mathrm{~cm}$ in diameter mostly from slash piled for burning adjacent to a recently cleared plot of ground. One apparently healthy tree was attacked. Adult tunnels were mostly biramous, although one branch was usually much longer.

The tunnels were cut into the wood. Egg niches were not seen in new tunnels. Schwarz, in the original description, reported seeing a few eggs loose in frass in the egg gallery. He also reported that the xylophagous larvae follow the grain of the wood for about 8 cm before they emerge.

Notes. - The above treatment was based on my female homotype and on 22 other specimens. The holotype of bourreriae and the cotype of lima were examined.

## 2. Dendrosinus transversalis Blandford

Dendrosinus transtersalis Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6): 156 (Lectotype, female; San Andrés Tuxtla, Veracruz, Mexico; British Mus. Nat. Hist., present designation)
Diagnosis.- This species is easily distinguished by characters summarized in the above key.

Female.- Length $3.3-4.0 \mathrm{~mm}$, 1.5 times as long as wide; color black, with legs, antennae, and frontal pubescence reddish.

Frons broadly planoconcave from vertex to a narrow, weak, transverse impression immediately above weakly elevated epistomal margin; epistomal lobe narrow; surface dull, finely, closely punctured in impressed area, minutely granulate at sides and above; vestiture short, suberect, abundant to just above upper level of eyes, golden to reddish. Eye
entire. Antennal club wider than long, sutures subangulately procurved, 3 reaching middle.

Pronotum 0.84 times as long as wide; outline as in bourreriae except feebly emarginate in front; anterolateral angles usually with a small cluster of minute, rudimentary asperities (not always present); surface dull, not clearly punctured or reticulate; vestiture short, semirecumbent, black, moderately abundant, hairlike.

Elytra 1.15 times as long as wide, 1.7 times as long as pronotum; widest one-third from base, sides arcuate from base, rather broadly rounded behind; crenulations on basal margins small, narrow, extended as in bourreriae, scutellar notch also similar; strial grooves narrowly impressed, punctures obsolete; interstriae about three times as wide as striae, 1 on right side twice as wide as 1 on left side, surface dull, not clearly marked by punctures, bases of 1-5 submarginally crenulate. Declivity convex, gradual, as on disc; abdomen ascending to meet elytra. Vestiture as in bourreriae.

Male. - Similar to female except frons very slightly more strongly impressed.

Distribution. - Veracruz to Costa Rica.
MEXICO: Veracruz: San Andrés Tuxtla, Sallé. COSTA RICA: Guapiles, Limón, 22-VII-66, 100 m , No. 108 , woody vine, S. L. Wood.

Fig. 92. Dendrosinus hourreriae: A, adult; B, head; C, proleg: D, antenna. (After Schwarz 1920:225.)

Host.- A woody vine (liana).
Biology.- The parental tunnels were biramous, about as described for bourreriae. Eggs and larvae were not found in the new galleries. The host was a cut woody vine 8 cm in diameter. Superficially it was very similar in growth habit and habitat to Celtis iguanae; it had spines on lateral twigs almost identical to that plant, but the leaf was very different. The beetles constructed small maturation feeding tumnels in branches less than 2 cm in diameter of the same host.

Notes.- This species was named from two syntypes, both of which were examined. One of them, a female, was selected and is here designated as the lectotype of the species. The above treatment was prepared from the lectotype and a series of 61 Costa Rican specimens.

## Genus Carphotoreus Wood

Carphotoreus Wood, 1973, Great Basin Nat. 33:171 (Type-species: Chatophloeus alni Bright, original designation)
Diagnosis. - This genus superficially resembles certain Chactophlocus species, but it is distinguished by the 6 -segmented antennal funicle, by the more widely distributed crenulations on the basal margins of the elytra, by the absence of submarginal crenulations on the elytral bases, by the visible scutellum, by the different arrangement and form of pronotal asperities, and by other characters.

Description.- Length $1.5-1.6 \mathrm{~mm}, 2.14$ times as long as wide.

Frons dimorphic, moderately concave in male, flattened or convex in female; eye elongate-oval, entire; scape moderately long, funicle 6 -segmented, club flattened, almost symmetrical, three nonseptate sutures indicated. Pronotum wider than long, anterolateral areas with a few asperities. Scutellum small, visible. Elytra suturally emarginate at base, a row of marginal crenulations at base, submarginal crenulations entirely absent; striate; declivity simple. Anterior coxae moderately separated. Third tarsal segments slender.

Distribution.- Oaxaca; only one species is known.

Notes.- The position of this genus is uncertain. It could be placed near Carphobius

Blackman except that the eye is not emarginate and the anterolateral areas of the pronotum are asperate. Within the American Hylesinini it is probably nearest Phlocosimus Chapuis, although the antennal funicle and vestiture suggest that the relationship is remote.

## Carphotoreus alni (Bright)

Chaetophlocus almi Bright. 1972, Canacian Ent. 104:1492 (Holotype, female; t2 km or 26 miles S Juchatengo, Oaxaca, Nexico; Canadian Nat. Coll.)
Diagnosis. - This species superficially resembles certain Chaetophlocus species, but it is distinguished by the sutural emargination at the base of the elytra, by the visible scutellum, by the absence of submarginal crenulations at the bases of the elytra, and by other characters.

Male.- Length 1.5-1.6 mm, 2.14 times as long as wide; color black, vestiture pale.

Frons moderately, rather broadly concave from epistoma to upper level of eyes; surface slightly rugose-reticulate, punctures sparse, minute, rather obscure; vestiture of rather short, coarse, uniformly distributed setae. Eye elongate-oval, three times as long as wide, entire; finely faceted. Antennal scape rather short, extending slightly beyond middle of eye; funicle 6 -segmented, distinctly longer than scape, club elongate-oval, almost symmetrical, strongly flattened, three sutures indicated, suture 1 evidently partly septate.

Pronotum 0.80 times as long as wide; widest at base, sides arcuately converging to moderately rounded anterior margin; surface most finely rugose-reticulate, punctures fine, moderately abundant, except anterolateral areas armed by several small, rather high, rounded granules. Vestiture rather short, moderately abundant, of stout and rather fine bristles; plural areas with some bifid hairs.

Elytra 1.5 times as long as wide, 2.0 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; basal margins suturally emarginate, each armed by a row of 10 crenulations to interstriae 7 , submarginal crenulations entirely absent; striae slightly impressed, punctures moderately deep, rather coarse; interstriae distinctly wider than siriae, distinctly convex, each bearing a
row of small, closely set granules. Declivity steep, convex; sculpture as on disc. Vestiture in ground cover of short, rather slender, subplumose setae, and interstrial rows of erect bristles; each bristle stout, each one-half to two-thirds as long as distance between rows or between bristles within a row.

Female. - Similar to male except frons broadly convex, subfoveate at center; some pronotal asperities much larger.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 85 km or 5.3 miles S Vatle Nacional, $24-\mathrm{V}-71,3300 \mathrm{~m}$, Alnus, D. E. Bright; Highway 131, 184 km or 115 miles S Oaxaca, 27-30-V-71, 2000 m , Aluus, D. E. Bright.

Fig. 93. Dendrosiuus bourreriae: gallery system. (After Schwarz 1920:223.)

Notes.- The above treatment was based on the type series.

## Genus CLADOCTONUS Strohmeyer

Cladoctomus Strohmeyer, 1911, Ent. Blätt. 7:17 (Typespecies: Cladoctonus affinis Strohmever, monobasic)
Hoplites Eggers, 1923 (nec. Dejean, 1833, etc.), Meded. Roy. Mus. Nat. Hist. Leiden 7:141 (Type-species: Hoplites hanosus Eggers, monobasic)
Hoplitontus Wood, 1961, Great Basin Nat. $21: 2$ (replacement name for Hoplites Eggers); Schedl, 1963, Ent. Abh. Ber. Tierk. Dresden 28:264. Synonymy Hoplitophthorus Wood, 1961, Great Basin Nat. 21:2 (Type-species: Hoplitophthorus sentosus Wood, monobasic); Wood, 1961, Great Basin Nat. 21:105 (corrected spelling); Schedl, 1963, Ent. Abh. Ber. Tierk. Dresden 28:264. Synonymy
Species in this genus are known from Cuba, Jamaica, Guadeloupe, Colombia, Bolivia, and Brazil, but at the present time they are not known from North or Central America. Eleven species have been described, six from the neotropics, one from the Philippine Islands, and four from Africa. Two of the African species breed in Acacia trees; one American species was taken from Citrus, and another from Pseudoolmedia sp. The one species observed was phloeophagous and monogamous. The genus almost certainly will be found in Central America.

## Genus PhLoEOSINUS Chapuis

Olonthogaster Motschulsky, 1866, Bull. Soc. Imp. Nat. Moscou 39:401 (Type-species: Olonthogaster nitidicollis Motschulsky, designated by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:126, suppressed, lutemat. Comm. Zool. Nomencl. 1981:67)
Phlocosinus Chapuis, 1869, Synopsis des Scolytides, p. 37 (Type-species: Hylesinus thujae Perris, designated by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:126)
Holonthogaster Geminer \& Harold, 1872, Cat. Coleopt. 9:2676. Replatement name
Phloeosinites Hagedom, 1907, Schr. Physik. Oekon, Ges. Konigsberg 47:119 (Type-species: Phloeosinites rehi Hagedorn, designated by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:126)
Hyledius Sampson, 1921, Ann. Nat. Hist. 7:35 (Typespecies: Hyledius asper Sampson, monobasic); Schedl. 1958, Tijd. Ent. 101:152. Synonymy
Phloeosinopsis Schedl, 1936, J. Fed. Malay St. Mus. 18:23 (Type-species: Phloeosinopsis armatus Schedl $=$ Phlocosinus spinifer Schedl, monobasic); Browne, 1963, Ent. Bericht. 23:53. Synonymy
Diagnosis.-Among genera in the western hemisphere Phloeosinus is allied to Cladoctonus Strohmeyer, from which it is easily
distinguished by the 5 -segmented antennal funicle and by the oblique sutures of the antennal club. The male frons is impressed, the pronotum is unarmed, the asymmetrical antennal club is rather strongly compressed, the eye is emarginate, and declivital interstriae 3 is armed in both genera.

Description.- Length $1.5-4.1 \mathrm{~mm}$, 1.8-2.1 times as long as wide; sexes usually dimorphic, male frons variously impressed, female flat or convex, male elytral declivity usually more coarsely armed. Eye elongate, moderately to very strongly emarginate; finely granulate; widely separated. Antennal scape elongate, unadorned; funicle 5 -segmented; club moderately asymmetrical, compressed, marked by three oblique, aseptate sutures. Pronotum usually wider than long, unarmed, surface punctate. Scutellum moderately large, distinct. Elytral bases armed by a row of marginal crenulations; striate; declivity convex, moderately steep, one or more interstriae armed by minute to very coarse teeth. Vestiture hairlike, except scalelike on elytral declivity in some species.
Distribution.- North America to Panama, Europe and Asia to North Africa and

Australia; 27 species and two subspecies occur in North and Central America, 35 species have been named from the eastern hemisphere.

Brology. - These monogamous, phloeophagous species construct simple, longitudinal, parental galleries that usually engrave the wood rather deeply. The male normally constructs the entrance tunnel and nuptial chamber; the female forms the egg gallery. The egg niches are usually rather large and conspicuous. Larval mines tend to wander in the general direction away from the parental mine. With few exceptions among American species, host plants belong to the Taxodioideae and the Cupressineae. The habits of some Indomalayan-Indonesian species differ drastically from American forms.

Notes. - Except for catalogs, the name Olonthogaster disappeared from the literature from 1866 to 1968, when the type was examined and associated with Phloeosinus (Wood 1969:119). In the interest of preserving a well-known, established name, an appeal to the International Commission on Zoological Nomenclature was made to conserve the name Phloeosinus.

Key to the Species of Phlocosinus

> 1. Declivital interstriae 2 broad, armed by several tubercles in female, usually by one or two tubercles near apex in male
> - Declivital interstriae 2 broad or narrow, entirely unarmed in both sex.................................................... 8
2(1). Declivital interstriae equally convex, except 2 in male often feebly impressed; interstriae 2 in male normally bearing several tubercles, tubercles subequal in size on all interstriae; anterior margin of mesosternum precipitous, subvertical, intercoxal piece protuberant, often conical; anterolateral margins of punctures of pronotum minutely asperate; Alaska to Quebec and Michigan; Picea glauca or Pinus; 1.8-2.5 mm than 2,2 on male never with more than two tubercles near apex; anterior slope of mesosternum gradual to rather abrupt, never protuberant; lateral punctures on pronotum almost never asperate; in Cupressineae
3(2). Declivital interstriae 4 in male armed by several tubercles near its apex,

- Declivital interstriae 4 quar laterally compressed; in Taxodium

Declivital interstriae 4 unarmed, tubercles on 1 larger and often much less numerous than on 3 and rather strongly, laterally compressed; in Juniperus and more strongly confused; declivital scales more slender and not extending anterior to base of declivity; male frons weakly impressed; Virginia to Texas
and Florida; 1................................ 2. taxodii taxodii Black

- Interstriae little more than twice as wide as striae, interstrial tubercles slightly larger and less strongly confused; declivital scales usually extending to middle of disc; male frons flattened, not impressed; Durango to Puebla; 2.0-2.6 mm ....

5(3). Interstriae on disc about twice as wide as striae; male interstriae 1 on declivity armed by three or four small teeth, 3 by six to nine teeth; vestiture very sparse; Durango and Hidalgo to Oaxaca; 2.4-3.2 mm
4. deleoni Blackman

- Interstriae two to four times as wide as striae; male interstriae 1 armed by eight or more teeth, 3 by ten or more teeth; vestiture rather abundant
6(5). Male declivital interstriae 1 and 3 weakly elevated, their serrations comparatively small, more slender; interspaces between pronotal punctures smooth, shining; interstrial tubercles on disc generally narrower, more numerous, higher; vestiture generally more abundant, declivital scales when present on interstriae 2 four times as long as wide; Nebraska and E Texas to Ontario, New Hampshire, and Georgia; 1.9-2.8 mm 5. dentatus (Say)

Male declivital interstriae 1 and 3 rather strongly elevated, their serrations large, very stout: interstrial tubercles on disc generally more broadly crenulate, not as pointed, less numerous; vestiture generally less abundant, declivital scales on interstriae 2 less than twice as long as wide
$7(6)$. Smaller; interspaces on pronotum marked by rather numerous points and/or minute lines; submarginal crenulations at elytral bases smaller, less abundant, marginal ones usually smaller, teeth on male declivital interstriae 1 less strongly compressed, their anterior profiles usually evenly arcuate from base to apex; Chiapas; $1.8-2.5 \mathrm{~mm}$

- Larger; interspaces on pronotum at most marked by rather sparse points; submarginal crenulations at elytral bases rather coarse, more numerous, marginal ones usually larger; teeth on male interstriae 1 strongly compressed, their anterior profiles angulate, distal portion almost straight; Washington and Idaho to Durango and Texas; 2.0-3.7 mm
8(1). Larger species, $2.5-4.3 \mathrm{~mm}$; interstriae 1 on male declivity unarmed or armed only at base of declivity, if armed in female tubercles often much smaller than on 3 or else striae as wide or wider than interstriae
Smaller species, $1.6-3.7 \mathrm{~mm}$; declivital interstriae 1 armed to apex in both sexes, teeth not smaller than those of 3 in females
$9(8)$. Discal interstriae less than twice as wide as striae; male interstriae 1 armed at base of declivity, 1 in female with teeth equal in size to those on 3
- Discal interstriae more than twice as wide as striae; male interstriae 1 unarmed throughout, if armed in female then tubercles much smaller than those on 3
10(9). Discal striae impressed, shallow punctures longitudinally elongate and subconfluent; interstriae convex; Alaska to California; Cupressus, etc.; 2.5-3.6 mm .....

8. cupressi Hopkins

- Discal striae not impressed, deep punctures circular or transversely oval, not at all confluent, summit of partitions between punctures in a row almost as high as interstriae; larger species, $3.0-4.6 \mathrm{~mm}$
$11(10)$. Punctures of discal striae averaging slightly smaller, surface of interstriae more irregular; pronotal punctures slightly larger; SE Arizona to Puebla, Edo. Mexico, and El Salvador; Cupressus; $3.0-4.1 \mathrm{~mm}$

9. baumanni Hopkins

- Punctures of discal striae averaging slightly larger, surface of interstriae less irregular; male interstriae 9 more acutely elevated; pronotal punctures slightly smaller; California; Cupressus; 3.0-4.6 mm ................................ 10. variolatus Bruck
12(9). Male frons shallowly, rather broadly impressed, median carina indistinct in both sexes; discal interstriae generally smooth, sculpture irregular with sparse, transverse lines; declivital punctures generally fine, shallow, obscure; female declivital interstriae 1 usually unarmed or with sparse, minute tubercles; Alaska to California; Cupressus, Sequoia, Thuja; 3.0-4.3 mm

11. sequoiae Hopkins

Male frons rather narrowly, deeply concave, median carina rather well developed in both sexes; discal interstriae generally closely subcrenulate, with numerous small tubercles; declivital punctures usually larger and deeper; female declivital interstriae 1 armed by regularly placed teeth of small to moderately large size; California and Arizona to Durango; Cupressus; 2.8-4.0 mm

## 13(8). Declivital teeth on inters

 those on 3 and very stronstriae 1 of male conspicuously less numerous than some teeth more than strongly, laterally as their transverse axis; male base of hairlike, female with hair and scales; usually larger, $2.2-3.8 \mathrm{~mm}$ male vestiture _ $\quad$ hairin, 14 Male declivital teeth on interstriae 1 almost as numerous as those on 3 , only slightly if at all compressed; usually smaller, $1.6-3.4 \mathrm{~mm}$I4(13). Pronotum and frons very slightly more coarsely, more sparsely punctured; upper half of frons usually devoid of granules; British Columbia and Alberta to Washington; Juniperus; $2.4-2.8 \mathrm{~mm}$................... 13. scopulorum scopulorum Swaine

- Pronotum and frons more finely, more closely punctured; upper half of frons with a few granules, lower half more closely granulate; S ldaho to Texas; Juniperus; $2.2-3.7 \mathrm{~mm}$

> 14. scopulorum neomexicanus Blackman

15(13). Vestiture on elytral declivity often sparse, hairlike in male, either hairlike or scalelike in female; declivital interstriae 2 at least as wide as 1 or 3 (narrowed in occasional males of punctatus)

- Declivital vestiture at least partly scalelike in both sexes (almost hairlike in male hoferi); left declivital interstriae 2 narrower than 1 or 3 on lower half
(except some arizonicus) ..................... (except some arizonicus)
16(15). Declivital vestiture hairlike in male, at least partly scalelike in female (commonly abraded in both sexes); male interstriae I almost always with fewer teeth than on 3; interstriae variable, almost smooth and punctate (southern) to rather coarsely rugose-tuberculate; S Alaska and N Idaho to California and W Nevada; 1.9-3.4 mm
- Declivital vestiture harlike inctatus LeConte
- Declivital vestiture hairlike in both sexes; declivital teeth on interstriae I and 3

17(16). Declivital interstriae 1 and 3 very weakly elevated, their minute tubercles reduced in number to about two to six; elytra subglabrous, bright shining, usually reddish brown, discal interstriae not at all granulate; S Oregon to California; Libocedrus decurrens; $1.8-2.2 \mathrm{~mm}$
numerous and larger; larger species, $2.0-3.4 \mathrm{~mm}$
18(17). Declivital interstriae densely punctured, surface irregular but subcrenulate or
tuberculate only toward declivity; pronotal punctures very tuberculate only toward declivity; pronotal punctures very close; declivital tubercles smaller and less abundant; subglabrous; S Oregon to California;
Libocedrus decurrens; $2.0-2.7 \mathrm{~mm} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ~ 17 . ~ f u l g e n s ~ S w i n ~$

- Discal interstriae tuberculate to base, few punctures visible; pronotal punctures not as densely placed; declivital interstrial tubercles larger and more numerous; elytral vestiture longer and more abundant
19(18). Elytral vestiture very fine, rather sparse; male frontal excavation deeper, larger; devoid of a carina in both sexes; SW Wyoming to Arizona and New Mexico; Juniperus; 2.3-3.3 mm

18. furnissi Blackman

- Elytral vestiture moderately coarse, abundant; male frontal excavation less extensive, not as deep; a conspicuous carina on lower half of frons in both sexes; Ontario and Minnesota to New Brunswick and New York; Thuja occidentalis; $2.0-2.9 \mathrm{~mm}$

19. canadensis Swaine

20(15). Male frons shallowly (rather deep in hoppingi), rather narrowly excavated, excavation ending well below upper level of eyes, with an acutely elevated, well developed, longitudinal, median carina extending from epistomal margin at least two-thirds of distance to upper level of eyes; declivital interstriae 5 each usually bearing six or more teeth in both sexes
Male frons deeply, broadly excavated, impression extending to or above upper level of eyes, usually devoid of a median carina, less commonly with a rudiment on lower third; female frontal carina partly reduced (except keeni); declivital interstriae 5 each usually armed by four or fewer teeth
21(20). Male frons moderately to strongly concave; male declivital teeth coarse; stout, conspicuously larger than those on 5 or 7 or those of female; British Columbia to California; Libocedrus, Juniperus, Cupressus, etc.; $1.7-2.2 \mathrm{~mm}$
20. hoppingi Swaine

- Male frons feebly to shallowly, transversely impressed; male declivital teeth on interstrial 1 and 3 not larger than those on 5 and 7 or those of female
22(21). Declivital interstriae 2 glabrous in both sexes, smooth except for nonsetiferous, minute points; declivital striae 1 and 2 usually each wider than interstriae 2
Declivital interstriae 2 bearing numerous scalelike setae, scales arising from confused punctures; declivital striae 1 and 2 each distinctly narrower than interstriae 2
23(22). Declivital striae 1 and 2 with punctures coarsely, deeply impressed; discal
strial punctures larger, more sharply impressed; Napa to Colusa counties, Califormia; Cupressus sargentii; $1.7-2.4 \mathrm{~mm}$ pressed; discal strial punctures somewhat smaller, less clearly impressed; Arizona; Cupressus arizonica; 1.8-2.3 mm

22. arizonicus Blackman

Discal interstriae little if any wider than striae; longest erect bristles on decliv-
24(22). Discal interstriae little if any wider than striae; longest erect bristles on decliv-
ital interstriae hairlike; Oregon to California; Libocedrus decurrens, etc.; $1.6-2.0 \mathrm{~mm}$
23. antennatus Swaine

Discal interstriae twice as wide as striae; longest, erect bristles on discal interstriae, flattened, scalelike; Hidalgo to Guatemala; Cupressus; $1.7-2.3 \mathrm{~mm}$

25(20). Declivital interstriae 1 and 3 rather weakly elevated, each armed by three to five teeth, striae 4-7 weakly if at all impressed

- Declivital interstriae 1 and 3 rather strongly elevated, each armed by eight or more teeth in both sexes, striae 4-7 more strongly impressed posteriorly
26(25). Vestiture on elytral declivity primarily hairlike in both sexes, scales six or more times as long as wide; male carina short, restricted to epistomal area; male declivital teeth small, little if any longer than their basal width; California; Cupressus sargentii; $1.5-2.1 \mathrm{~mm}$

Vestiture on elytra primarily scalelike, most scales stout, less than four times as
27(26). Male frontal carina reduced to an epistomal tubercle; male declivital teeth on interstriae 1 and 3 unusually long and slender, some two or more times longer than their basal width; Arizona and New Mexico to Chihuahua; Cupressus arizonica, Juniperus deppeana; $1.6-2.0 \mathrm{~mm}$............................. 26. spinosus Blackman

- Male frontal carina weak, extending from epistomal margin to deepest point of concavity; male declivital teeth on interstriae 1 and 3 smaller, little if any longer than basal width; S California: Cupressus; $1.5-2.0 \mathrm{~mm}$
28(25). Male frons bearing a short median carina on lower half of lower..................................................................antalis Blope of frontal impression; declivital tubercles on interstriae 1 and 3 smaller, each interval usually bearing 12 or more; scalelike setae on declivity more abundant; British Columbia and Washington to N Idaho; Chamaecyparis nootkatensis; 2.1-2.8 mm

28. keeni Blackman

- Male frons devoid of median carina except for a small, marginal, epistomal tooth; declivital tubercles on interstriae 1 and 3 larger. each interval usually bearing 9 or fewer; S British Columbia and North Dakota to Arizona and W Texas; Juniperus; 1.7-2.4 mm

29. hoferi Blackman

## 1. Phloeosinus pini Swaine <br> Fig. 94

Phloeosimus pini Swaine, 1915, Canadian Ent. 47:362 (Lectotype, female; Riding Mountains, Mauitoba, Canada; Canadian Nat. Coll., designated by Bright, 1967, Canadian Ent. 99:677)
Phlocosinus piceae Swaine, 1934, Canadian Ent. 66:205 (Holotype, female; Berry Mountain Brook, Cascapedia River, Caspé Co., Quebec, Canada; Canadian Nat. Coll.): Wood, 1957, Canadian Ent. 89:400. Synonymy
Phlocosinus alaskanus Blackman. 1942, Proc. U.S. Nat. Mus. 92:409 (Holotype, male; Eagle, Alaska; U.S. Nat. Mus., 55396); Wood, 1971. Great Basin Nat. 31:149. Synonymy
Diagnosis. - This appears to be a unique, primitive species that lacks sexual dimorphism except for the impressed male frons; all declivital interstriae are about equally convex and equally, finely tuberculate in both sexes.

Male.- Length $1.8-2.5 \mathrm{~mm}, 1.9$ times as long as wide; color dark brown.

Frons concave, variably concavity extending from just below upper level of eyes to level of antennal insertion, occupying less than half to more than two-thirds of frontal area, a rather weakly elevated median carina usually present on lower slope in most specimens; surface shining, occasional irregular areas of feeble reticulation sometimes present, with rather fine, moderately abundant punctures intermixed with equally abundant rounded granules; vestiture hairlike, inconspicuous.

Pronotum 0.78 times as long as wide; widest on basal third, sides strongly arcuate on basal two-thirds to very strong constriction just behind rather broadly rounded anterior margins, surface somewhat irregular, shining, often with irregular patches of feeble reticulation, punctures rather large, deep, moderately abundant, some on basal half occasionally granulate; vestiture hairlike, rather short, moderately abundant.

Elytra 1.3 times as long as wide, 2.0 times as long as pronotum; sides almost straight and parallel on basal half, rather broadly rounded behind; basal margins each armed by 10 crenulations; striae narrowly, rather strongly impressed, punctures rather indistinctly impressed; interstriae about twice as wide as striae, moderately convex, punctures replaced by an indefinite, staggered row of rather coarse, subcrenulate tubercles on each interstriae. Declivity convex, steep; striae less strongly impressed than on disc; interstriae with close, confused, fine punctures; each equally armed by a uniseriate row of about eight pointed tubercles, those on 2 sometimes partly reduced in size and number, 1 weakly elevated toward suture. Vestiture hairlike on disc, changing toward declivity to moderately abundant, subsquamose, short, ground cover and interstrial rows of slender bristles, each bristle slightly shorter than distance between rows.

Female. - Similar to male except frons convex, carina more consistently present.

Distribution.-Alaska to Quebec and Michigan.
ALASKA: Eagle, Hopk. U.S. I170c, Picea glauca, W: N. Osgood. CANADA: Manitoba: Grassy River, 27 -VIII72, P. glauca, D. E. Bright: Riding Mountains, Pinus banksiana, J. M. Swaine. Northwest Territories: Aklavik, $27-\mathrm{IV}, 10 \mathrm{~V}, 18-\mathrm{VI}-3 \mathrm{I}$, Nos. 206, 222, 234, O. Bryant. Quebec: Gaspé Co., 2-VIII-31. 16-VIII-34, Picea glauca, E. B. Watson. USA: Michigan: Grande Island, Hopk. U.S. 3775 and 3755 a .

Hosts.- Picea glauca, Pinus banksiana.
Biology.-Specimens have been reared from spruce branches and from a broken top of Jack pine.

Notes. - The above treatment was based on my male homotype from Gaspé Co. that was compared to the types of both pini and piceae and a female bearing identical data; these types previously had been compared directly to one another. The type series of alas-
kamus was kamus was examined in addition to 84 other
specimens. specimens.

## 2. Phloeosinus taxodii taxodii Blackman Fig. 95

Phlocosinus taxodii Blackman, 1922. Mississippi Agric. Expt. Sta. Tech. Bull. 11:61 (Holotype, female; Columbia, Mississippi; U.S. Nat. Mus., 55410)
Diagnosis. - This species is distinguished from dentatus (Say) by the presence of several small teeth at the base of declivity on interstriae 4, by the larger, less numerous granules on the declivital interstriae, and by the slightly narrower, weakly convex, declivital interstriae 2.

Male.- Length $1.9-3.0 \mathrm{~mm}, 1.9$ times as long as wide; color dark brown.

Frons weakly convex, a slight transverse impression just above upper level of antennal insertion; surface shining, punctured above and laterally, most punctures replaced by rather large, rounded granules in central area; a moderately well-developed, acute, median carina extending from upper level of eyes to epistomal margin; vestiture hairlike, inconspicuous.

Pronotum 0.81 times as long as wide; widest at base, sides convergently arcuate, a moderate constriction just before broadly rounded anterior margin; surface shining, punctures close, deep, interspaces about half as wide as diameters of punctures; vestiture hairlike, short, rather abundant.

Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, rather broadly rounded behind; each basal margin armed by $10-11$ crenulations; striae narrowly impressed, small punctures obscurely impressed; interstriae three to four times as wide as striae, surface shining, with narrow, confused, transverse crenulations. Declivity convex, rather steep; interstriae 1 and 3 moderately elevated and armed by coarse teeth, those on 1 slightly larger and less numerous, eight teeth on 1,10 or 11 on 3, 2 weakly convex and armed by two or three small granules at base and one just before apical margin, $4-9$ each with five or more smaller teeth. Vestiture hairlike, part of ground vestiture on declivity stout, almost scalelike.
Female.-Similar to male except frontal impression less pronounced, carina often absent; discal interstrial crenulations slightly higher; declivital teeth on elytra smaller, more slender, slightly more numerous, equally abundant on interstriae 2; ground vestiture on elytra partly scalelike, each scale about two or three times as long as wide.

Distribution. - Texas and Virginia to Florida.

USA: Florida: Apalchea, Jacksonville, La Bell, Mariana, Monroe Station, Oneco. Georgia: Sea Island. Louisiana: Frenier, New Orleans, Patterson. Mississippi: Columbus, Holly Springs. North Carolina: Boardman, Wilmington. South Carolina: Lumber, New Landing. Virginia: Cape Henry, Franklin. Portsmouth.

Host.- Taxodium distichum.
Biology.- This species breeds in the limbs and bole of the host species. The gallery system is essentially as described for the genus.

Notes. - The above descriptions were based on the holotype and on 109 other specimens.

## 3. Phloeosinus taxodii taxodiicolens Wood

Phloeosinus taxodiicolens Wood, 1956, Canadian Ent. 88:250 (Holotype, male; Tamazunchale, San Luis Potosi, Mexico; Snow Ent. Coll., Univ. Kansas)
Diagnosis.- As in t. taxodii except discal striae distinctly wider; discal interstrial crenulations lower, wider, less numerous; ground vestiture in male more nearly scalelike, extending to near middle of disc in both sexes; declivital teeth usually slightly smaller.

Male.- Length $2.0-2.6 \mathrm{~mm}, 1.8$ times as long as wide; color dark brown.

Distinguished from the northern race by characters mentioned above.

Distribution.- Durango to Puebla.
MEXICO: Durango: 20 km N Rodeo, 22-VI-53, 1400 m, Taxodium, S. L. Wood. San Luis Potosí: Tamazunchale, 21-VI-53, 800 m . Taxodium, S. L. Wood. Puebla: Matamoros, 14-VI-67, Taxodium, S. L. Wood.

Host.- Taxodium mucronatum.
Bıology. - Essentially as in t. taxodii.
Notes. - The above treatment was based on the type series of 76 specimens and on 5 other specimens. It was treated as a distinct species until a series from Durango was found to exhibit characters intermediate between those usually seen in series from the United States and from Mexico.

## 4. Phloeosinus deleoni Blackman

Phloeosinus deleoni Blackman, 1942. Proc. U.S. Nat. Mus. 92:454 (Holotype, male; Jacala, Hidalgo, Mexico; U.S. Nat. Mus., 55411)
Diagnosis.- This unique species is allied to the following three species as indicated by the armature of declivital interstriae 2 and the sculpture of the male frons; however, it is not closely related to any of them. The sculpture is much finer and the elytral tubercles are reduced in size and number, particularly in the male, and the declivity begins at the middle of the elytra.

Male.- Length $2.4-3.2 \mathrm{~mm}, 1.9$ times as long as wide; dark brown, elytra usually of lighter color.

Frons broadly, transversely impressed on middle third, convex above, gradually ascending to epistomal margin below; a weak, median carina extending from upper level of eyes to epistomal margin; surface shining, closely, rather coarsely punctured, a few punctures very feebly granulate; vestiture fine, hairlike, rather abundant but noticeable only near epistoma.

Pronotum 0.86 times as long as wide; outline and sculpture essentially as in taxodii.

Elytra 1.24 times as long as wide, 1.56 times as long as pronotum; sides almost straight and parallel on basal half, then slightly, arcuately convergent and rather broadly rounded behind; basal margins each armed by 12 crenulations; striae narrowly, moderately impressed, punctures rather fine,
deep; interstriae twice as wide as striae, shining, punctures usually with their anterior margins higher, about a fourth of them finely crenulate on 1 to 3 and on bases of other interstriae. Declivity convex, gradual, beginning at middle of elytra; interstriae 1 and particularly 3 weakly elevated, 1 armed by three or four pointed teeth, 3 by seven to nine teeth, middle ones pointed, 5 to 9 each with three to five shorter, blunt teeth; 2 as wide as 1 or 3 , armed by one small tubercle near apex in about half of males (tubercle on left elytron most commonly missing). Vestiture short, fine on disc, becoming stout toward declivity, almost scalelike on lower half, each scale three to six times as long as wide (some more slender setae also intermixed with scales).

Female.-Similar to male except frons more nearly convex; discal crenulations on interstriae larger and more abundant; declivital teeth slightly smaller, interstriae 1,2 , and 3 each with eight or nine pointed teeth of about equal size.

Distribution.- Durango and Hidalgo to Oaxaca.
MEXICO: Durango: 17 km W El Salto, 11-VII-64, Juniperus, E. E. Lindquist. Hidalgo: Jacala, 18-1-38, No. 662, Juniperus flaecida, D. DeLeon; 30 km N Zimapan, 11-VII-67, No. 192, Juniperus, S. L. Wood; State of Hidalgo (near Jacala), Vl-53, Juniperus, S. L. Wood. JaIisco: Guadalajara, $22-\mathrm{IV}-77$. Hopk. 60595, M. M. Furniss. Michoacán: Km 118 Toluca-Morelia. Oaxaca: 120 km S Oaxaca, 11-V-71, 2000 m , Cupressus, D. E. Bright.

Host.- Juniperus flaccida, J. sp., Cupressus sp.

Biology.- This species breeds in the bole and larger branches. The gallery patterns were essentially as described above for the genus.

Notes. - The above descriptions were based on the holotype, allotype, and 3 paratypes and on 94 other specimens.

## 5. Phloeosinus dentatus (Say)

Fig. 95
Hylurgus dentatus Say, 1826. J. Acad. Sci. Philadelphia 5:258 (Syntypes?; presumably Milton, Massachusetts; type evidently lost)
Dendroctonus (?) graniger Eichhoff, 1868, Berliner Ent. Zeitschr. 12:147 (Lectotype, male; Texas, labeled "Am. Bor."; U.S. Nat. Mus., present designation); Eichhoff, 1895, Proc. U.S. Nat. Mus. 18:608. Synonymy

Dendroctonus (?) haagi Eichhoff, 1868, Berliner Ent. Zeitschr. 12:148 (Lectotype, female; Amerique Boreale, U.S. Nat. Mus., present designation): Blackinan 1942, Proc. U.S. Nat. Mus. 92:452. Synonymy
Phlocosinus enixus Blackman, 192I, Mississippi Agric, Expt. Sta. Tech. Bull. 10:5 (Syntypes: Nachez, Mississippi; U.S. Nat. Mus.); Blackman, 1942, Proc. U.S. Nat. Mus. 92:452. Synonymy
Diagnosis.- This species is very closely related to taxodii Blackman, from which it is distinguished with some difficulty by the absence (usually) of teeth on interstriae 4 at the declivital base, by the smaller, more numerous discal interstrial crenulations, by the wider, flat, declivital interstriae 2 of the male, and by the finer, more slender declivital setae in both sexes.

Male.- Length $1.8-2.8 \mathrm{~mm}, 2.0$ times as long as wide; color dark brown, pronotum commonly darker than elytra.

Head and pronotum as described above for taxodii.

Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; outline and crenulations on basal margins as in taxodii; striae narrowly impressed, punctures small, impressed, somewhat obscure; interstriae three to four times as wide as striae, surface shining, almost smooth except armed by rather abundant setiferous, subcrenulate tubercles, smaller and evidently more numerous than in taxodii. Declivity as in taxodii except interstriae 2 flatter and slightly wider, two teeth nearest middle (usually second and third from apex) normally slightly larger, and interstriae 4 unarmed. Vestiture hairlike; ground vestiture near apex stout in some specimens.

Female.-As in male except frons more convex; elytra more slender, 1.3 times as long as wide; discal tubercles on interstriae slightly higher; declivital tubercles smaller, more slender, usually slightly more numerous, interstriae 2 usually also armed; declivital vestiture mostly hairlike above, a few slender scales present on lower half, each scale usually four or more times as long as wide.

Distribution.- Nebraska, Ontario, and New Hampshire to Texas and Georgia.
CANADA: Ontario: E Ontario. USA: Alabama: Mobile. Arkansas: "Ark.," Lyme, Rowayton. District of Columbia: Washington. Georgia: Thomasville. Illinois: Lyons. Iowa: Mt. Carmel, Shenandoah. Kansas: Douglas Co., Fowler, Lawrence, Osborne Co., Salina. Kentucky: Lexington. Maryland: Bladensburg, Glen Echo, Piney

Point, Plummers Island. Massachusetts: Lawrence, Walpole in Norfolk Co. Minnesota: Monticello. Mississippi: Agricultural College, Columbus, Gulfport, Natchez, Ripley, Wallerville. Nebraska: St. Paul. New Hampshire: Webster. New Jersey: Anglesea, Bamber, New Milford New York: Huntington on Long Island, Ithaca, New York, Peekskill, Syracuse, West Point. North Carolina: Durham, Elizabeth, Tryon. Ohio: Cleveland, Gypsum. Pennsylvania: Hummelstown, York Co. South Carolina Greenville, Yorkville. South Dakota: Ft. Pierce, Wes sington Springs. Tennessee: "Tenn." Texas: Austin, Bostrop, Dallas, Houston, La Grange. Virginia: Ft. Monroe, Falls Church, Frederickshurg, Mt. Vernon, Onville, Pennington Gap. Richmond, Rosslyn, Virginia Beach. West Virginia: Bayard, Kanawha Station, Wood Co.

Hosts.- Chamaecyparis thyoides, Juniperus virginiana, Thuja occidentalis.

Biology. - Both limbs and bole of the host are attacked. The gallery system is as described above for the genus.

Notes.- The above descriptions were based on a male and a female from Long Island, New York (Melville and Wayandanch, respectively), that agree with LeConte's representatives of this species. The type evidently is lost. In addition, 552 other specimens were examined. Two male syntypes of graniger are in the U.S. National Museum; the first is here designated as the lectotype of graniger Eichhoff. One female syntype of haagi is also in the U.S. National Museum; it is here designated as the lectotype of haagi Eichhoff. All other syntypes of these two Eichhoff species presumably were destroyed with the Hamburg Museum.

## 6. Phloeosinus palearis Wood

Phloeosinus palearis Wood, I969, Brigham Young Univ. Sci. Bull.. Biol. Ser. $10(2): 2$ (Holotype, male; Chiapa de Corzo, Chiapas, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from serratus (LeConte) by the smaller size, by the numerous minute points and/or fine lines in the interspaces between punctures on the pronotal dise, by the less numerous, smaller submarginal crenulations at the elytral bases, and by the less strongly compressed teeth on the male elytral declivity, the anterior profile of each tooth usually evenly arcuate (abruptly angled in serratus).

Male.- Length 1.9-2.5 mm, 1.95 times as long as wide; color very dark brown.

Frons feebly convex, almost flat, lower fourth gradually ascending to epistomal margin; lower half marked by a fine, low, median
carina; surface smooth, with rather fine, deep, close punctures, some subgranulate in area mesad from upper half of eye; vestiture fine, moderately long, rather abundant. Vestiture on antennal club short, more abundant than in allied species.

Pronotum 0.82 times as long as wide; widest near base, sides strongly, convergently arcuate to moderate constriction just before broadly rounded anterior margin; surface smooth, with some minute points and lines in interspaces between moderately large deep punctures; width of interspaces one-fourth to equal in width to diameter of a puncture. Vestiture fine, rather short, moderately abundant.

Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; basal margins armed by 12 crenulations on interstriae 2-9; striae narrowly impressed, small punctures somewhat obscurely indicated; interstriae about three times as wide as striae, feebly convex, surface smooth but irregular, punctures moderately coarse, close, confused, their anterior margins usually elevated, some rather coarsely crenulate at base. Declivity convex, rather steep; striae less strongly impressed; interstriae 1 and 3 moderately, $5,7,8$, and 9 less strongly elevated, these and 6 armed by rather coarse teeth, those on 3 and particularly on 1 larger, 2 bearing two teeth near apex, 2 and 4 flat, finely punctured; interstriae 1 bearing eight teeth, each only slightly compressed and usually with anterior profile evenly arcuate, 3 bearing 13 teeth with none of them compressed. Vestiture scanty, but stout, some setae almost scalelike.

Female.- Similar to male except frons more strongly convex and more extensively granulate; pronotal lines and points much more abundant; a few elytral crenulations extend almost to declivity; declivital teeth smaller with interstriae 2 and 4 armed by at least a few small teeth; declivital vestiture largely of scales, each only slightly longer than wide.

Distribution.- Chiapas.
MEXICO: Chiapas: 17 km E Chiapa de Corzo, 17-vl64.2300 m , No. 710 , Juniperus, S. L. Wood; 40 km SE Teopisca, 18-V-69, Juniperus. D. E. Bright.

Host.- Juniperus sp.
Biology. - The type series was taken from a broken branch less than 4 cm in diameter.

The parental galleries were as described for the genus.
Notes.- The above description was based on the type series of 16 specimens, and on 4 other specimens.

## 7. Phloeosinus serratus (LeConte) Fig. 95

Hylesinus serratus LeConte, 1868, Trans. Amer. Ent. Soc. 2:170 (Holotype, male; Middle States; Mus. Comp. Zool.)
Phlocosinus utahensis Swaine, 1915, Canadian Ent. 47:363 (Lectotype, female; Stockton, Utah; Canadian Nat. Coll., designated by Bright, 1967, Canadian Ent. 99:677); Wood, 1971, Great Basin Nat. 31:150. Synonymy
Phlocosinus rugosus Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):9 (Lectotype, female; Scaffold Meadow, Sequoia N. F., California, Canadian Nat. Coll., 9259, designated by Bright, 1967, Canadian Ent. 99:677); Wood, 1974, Great Basin Nat. 34:286. Synonymy
Phloeosinus juniperi Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Bull. 14(1):10 (Lectotype, female; Scaffold Meadow, Tulare Co., California; Canadian Nat. Coll., designated by Bright, 1967, Canadian Ent. 99:677); Wood 1971, Great Basin Nat. 31:150. Synonymy
Phloeosinus aeiculatus Bruck, 1931, Pan-Pacific Ent. 7:127 (Holotype, male; Chiricahua Mountains, Cochise Co., Arizona; California Acad. Sci.); Wood, 1971, Great Basin Nat. 31:150. Synonymy
Phlocosinus neotropicus Schedl, 1939, Proc. Roy. Ent. Soc. London 8(1):12 (Holotype, female; Jamaica; British Mus. Nat. Hist.): Wood, 1978, Great Basin Nat. 38:387. Synonymy
Diagnosis.- This species is allied to palearis Wood, but is easily distinguished by characters included in the above key. It varies geographically as noted below.

Male.- Length $2.0-3.7 \mathrm{~mm}, 2.0$ times as long as wide; body very dark brown, elytra often reddish brown.

Frons convex above, flattened toward center, transversely impressed just above level of antennal insertion, ascending toward epistomal margin; surface shining, with rather abundant, isolated, rounded granules, their size smaller below; vestiture hairlike, fine, rather abundant.

Pronotum 0.81 times as long as wide; essentially as described for taxodii.

Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, rather broadly rounded behind; basal margins each armed by 10-11 crenulations; striae
narrowly impressed, punctures obscurely indicated; interstriae more than twice as wide as striae, shining, punctures rather coarse, confused, their anterior margins weakly to strongly elevated, a few forming small, narrow crenulations (number and height of crenulations greater in specimens from extreme southern part of distribution). Declivity convex, rather steep; interstriae 1 and 3 moderately elevated and coarsely serrate, teeth larger and laterally compressed near middle on 1,1 bearing 7 to 11 teeth, 3 bearing 11 to 16 teeth (higher numbers more common in southeastern part of range), 5 and 7 armed by about five to six teeth, 6,8 , and 9 usually bearing a few small tubercles, 2 and 4 unarmed and punctured, 2 impressed. Vestiture consisting of hair on disc; ground cover on declivity subscalelike, with median rows of short, interstrial hair.

Female.- Similar to male except frons convex, a small, subfoveate impression at center; discal interstrial crenulations larger, wider, more numerous; declivital interstriae 1 and 3 less strongly elevated, teeth much smaller, all interstriae armed but 2 with fewer smaller teeth; declivital scales more abundant, stouter, mostly about twice as long as wide.
Distribution. - Washington and Idaho to Hidalgo and Texas, Jamaica.
USA: Arizona: Carr Canyon in Huachuca Mts., Chiricahua Mts., Dragoon Mts. in Cochise Co., Ft. Apache, Grand Canyon, Greer, Lakeside, Paradise, Prescott N. F., Santa Rita Mts., Sycamore Springs, Williams. California: Alturas, Angora Lake, Buck Creek near Warner in Modoc Co., Fallen Leaf Lake, Grass Lake in Siskiyou Co., Hackamore, Hat Creek, Likely in Modoc Co., Madeline, Scaffold Meadow in Tulare Co., Sequoia N. F., Willow Ranch in Modoc Co., Yosemite N. P. Idaho: Centerville. New Mexico: Capitan Mts., Manzano, Santa Catalina Mts., Santa Fe, Stevens. Oregon: Beatty, Hood River, Klamath Falls, Ochoca N. F., Prineville, Redmond. Texas: Dallas, Davis Mts., Jeff Davis Co. Utah: Beaver, Oak Creek Canyon in Millard Co., Stockton. MEXICO: Chihuahua: Creel, La Magdalena. Durango: 16 and 48 km in $W$ Durango, El Salto, La Zarca. Hidalgo: Chico N. P. Tlaxcala: Capulapan. JAMAICA: Chinchona.

Hosts.-Juniperus deppeana, J. monosperma, J. occidentalis, J. osterosperma, J. scopulorum.

Biology. - The bole and larger limbs are attacked by this species. The gallery system is about as described for the genus.

Notes. - The above descriptions were prepared largely from a male and a female from La Zarca, Durango. The type of serratus was examined and, although it has the large number of teeth more commonly characteristic of the southeastern part of the range, the size and other features suggest it came from California or Oregon. The second specimen in the type series is not of this species. In addition to these two specimens the types of utahensis, juniperi, rugosus, and aciculatus, and 431 other representatives of this species were examined. The rugosus of Blackman (1942) is actually punctatus LeConte.

Blackman (1942) divided this species into four allopatric units. While certain specimens from each area do fit his morphological definitions of species rather well, he does not indicate the variability within series or the overlap in these variations between series. Although most of the northern California and Oregon specimens are rather clearly different from the La Zarca, Durango, series, they are not nearly as distinct from the El Salto, Durango, series. There appear to be slight clinal differences from northwest to southeast increasing the number of declivital teeth on male interstriae 1 and 3 and in the size and number of discal interstrial crenulations (not really measurable). With the limited material at hand, in view of the broad availability of potential hosts over the entire distribution, it appears that only one species should be recognized. When sufficient material is available for study, it may be necessary to reduce $p a$ learis Wood to subspecific rank; however, at the present time such action is not justified.

## 8. Phloeosinus cupressi Hopkins <br> Figs. 94, 96

Phloeosinus cupressi Hopkins, 1903, U.S. Bur. For. Bull. 38:35 (Holotype, male; Golden Gate Park, San Francisco, California; U.S. Nat. Mus., 55406)
Phloeosinus nitidus Swaine, 1924, Canadian Ent. 56:145 (Holotype, male; Santiam Nat. For., Oregon; Canadian Nat. Coll., 730); Wood, 1971, Great Basin Nat. 31:148. Synonymy
Phlocosinus blackwelderi Blackman, 1943, Proc. U.S. Nat. Mus. 94:397 (Holotype, male; Circito, Canal Zone, Panama; U.S. Nat. Mus., 56576); Wood, 1971, Great Basin Nat. 31:148. Synonymy
Diagnosis. - This species is rather closely related to baumanni Hopkins and variolatus Bruck, but it differs from both by the smaller
size, by the more narrowly, more strongly impressed discal striae, by the somewhat more coarsely sculptured discal interstriae, and by the reduced male frontal carina.

Male.- Length 2.5-3.6 mm, 1.9 times as long as wide; color dark brown to black with elytra lighter, usually dark reddish brown.

Frons concave on median half from upper level of eyes almost to epistomal margin; surface smooth and shining, with a few moderately large, isolated granules on margins of concavity on slightly more than upper half, with moderately abundant, rather large punctures at sides and above except in area of granules; a moderately large, median tubercle just above epistomal margin; vestiture hairlike, fine, rather short, moderately abundant.

Pronotum 0.85 times as long as wide; as in taxodii except interspaces between punctures marked by moderately abundant, fine points.

Elytra 1.3 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind, with declivital tubercles interrupting outline; basal margins each armed by 12 crenulations; striae narrowly, moderately impressed to base, punctures obscurely impressed; interstriae at least twice as wide as striae, punctures mostly obscurely impressed, those on 1 to 3 and sometimes 4 crenulate on their anterior margins, varying from low to rather coarse, crenulations on those from northern parts of range tending to be slightly larger. Declivity steep, convex; interstriae 2 narrowed and obsolete by upper fourth, 2 armed by 2 to 4 coarse teeth at upper margin, 3 slightly elevated and armed by a row of 8 to 12 coarse, rather blunt, closely set teeth, 5,7 , and 9 usually with about 3 to 5 smaller teeth, 1 below armed area smooth, with sparse, setiferous punctures. Vestiture hairlike, rather short, mostly in rows, not abundant; fine on disc, stout on declivity.

Female.- Similar to male except frons convex, with a median fovea near center, a fine, median carina from fovea to epistoma, surface closely, coarsely granulate; interstrial crenulations higher and evidently slightly more abundant; declivital interstriae 1 and 3 equally serrate to apex, all teeth smaller, 2 continued to apex, only slightly narrower than 1 or 3; declivital vestiture consisting of
abundant scales, each scale less than twice as long as wide.

Distribution.- Alaska to California. Also introduced into Panama, New Zealand, and Australia.

ALASKA: Juneau and Petersburg. CANADA: British Columbia: Mt. Benson in Vancouver Island, Vancouver. USA: California: Aptos, Berkeley, Callistoga, Carmel, Cooks Springs in Colusa Co., Costa Mesa, Cypress Ridge near Fairfax in Marin Co., Del Monte, Easton, Ft. Bragg, Los Catos, Mojave, Montara, Monterey, Mt. St. Helena, Napa Co., Oakland, Pacific Grove, Palo Alto, Paraiso Springs, Pasadena, Redlands, Salinas, San Francisco, San Mateo. Oregon: Klamath Falls. Washington: Fairfax, Mt. Rainier, Ogseagle Pass. OTHER COUNTRIES: Australia: Northarodge, New South Wales, 4-V47. Cupressus torulosa, P. H. Taylor. New Zealand: St. Heliers, Auckland, 29-V111-43, D. Spillar. Panama: Ciricito, Canal Zone, 4-IV-30, R. E. Blackwelder.

Hosts.- Chamaecyparis nootkatensis, Cupressus macrocarpa, C. sargentii, Sequoia sempervirens, Thuja plicata.

Biology. - The bole and limbs are selected for breeding; maturation feeding tunnels may also be constructed in tiny living twigs by young adults. When populations are high this species is said to attack and kill healthy trees (Blackman 1942:398). The gallery system appears to be as described for the genus.

Notes.- The above descriptions were based on the holotypes of cupressi, nitidus, and blackwelderi and on 521 other specimens.

Blackman (1942) divided this taxon into two allopatric species defined by differences in host, by supposedly smoother lateral interstriae, and by sinuate striae in the northern race. I find the discal interstriae of the northern race tend to be more coarsely, closely crenulate in specimens from Washington but finer in those from Alaska; the other characters vary about equally within series from both areas. None of the supposed differences, except host, appear sufficiently constant to be recognized in more than half the available material; therefore, until biological or other supporting evidence becomes available for separation, 1 must recognize only one species.

## 9. Phloeosinus baumanni Hopkins

Phloeosinus baumanni Hopkins, 1905, preprint of Proc Ent. Soc. Washington 7:79 (Holotype, male; Tacubaya, Distrito Federal, Mexico; U.S. Nat. Mus., 7517a)
Diagnosis.- This species is closely related to variolatus Bruck, but it is distinguished
with difficulty by characters summarized in the above key.

Male. - Length $3.0-4.1 \mathrm{~mm}, 1.9$ times as long as wide; color dark brown to black, elytra usually dark reddish brown.
Frons rather weakly, subconcavely impressed in central area; lower two-thirds bearing a fine, median carina; surface rather coarsely punctured, with a few coarse, isolated granules at sides above; vestiture fine, hairlike, more conspicuous along epistoma.

Pronotum 0.90 times as long as wide, otherwise as in cupressi.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; outline and basal margins as in cupressi; striae slightly impressed toward declivity only, punctures very coarse and deep, decreasing in size toward base; interstriae usually narrower than striae on posterior half, equal to or slightly wider than striae on anterior half, surface smooth and shining, undulating but not crenulate, punctures rather fine, their anterior margins usually slightly elevated. Declivity steep, convex; armature as in cupressi except interstriae 2 only slightly narrowed and continuing to apex. Vestiture as in cupressi except some scales present on interstriae 1 and 3.

Female.-Similar to male except frons convex, foveate at center, a median carina extending from fovea to epistoma; interstriae 2 and 3 with a few fine crenulations on dise; declivital interstriae 1 and 3 equally armed to apex, teeth slightly smaller, 4,6 , and 8 usually with fine teeth; declivital vestiture largely scalelike, each scale about twice as long as wide.

Distribution.-SE Arizona to El Salvador.
USA: Arizona: Rucker Canyon, Chiricahua Mts., 21 . VII-68, Cupressus arizonicus, D. E. Bright. MEXICO: Distrito Federal: Chapingo, 11-IX-49, C. benthami, J. P. Perry; Mexico City, 16-V-49, C. benthami, J. P. Perry; Tacubaya, Hopkins U.S. 1146 . Hidalgo: 32 km E Tulancingo, $10-\mathrm{VII}-67,2300 \mathrm{~m}$, C. benthami, S. L. Wood. Puebla: Iztaccihuatl-Popocatepet1 N. P., $9 \mathrm{~V}-72,3000 \mathrm{~m}$, Cupressus, D. E. Bright. Unknown state: San Juan, 25-I36, Cupressus, D. DeLeon. El SALVADOR: San Andres, 1979, C. lusitanica.

Hosts.- Cupressus arizonicus and $C$. benthami.

Brology.- This species bred in the bole larger than 25 in diameter in the two trees
observed. Both evidently were primary attacks on healthy trees. The tunnels were essentially as described for the genus.

Notes. - The above descriptions were based on the holotype and on I37 other specimens.

This species is very closely related to variolatus; some female specimens are extremely difficult to distinguish.

## 10. Phloeosinus variolatus Bruck <br> Figs. 94, 96

Phlocosinus cariolatus Bruck, 1931, Pan-Pacific Ent. 7:126 (Mount Saint Helena, Napa Co., California; California Acad. Sci.)
Diagnosis. - This species is so very closely related to baumanni Hopkins that occasional females are distinguished with great difficulty. The characters summarized in the above key will serve to distinguish these species.

Male. - Length 2.6-4.6 mm, 2.0 times as long as wide; color very dark brown to black. elytra usually lighter.

Frons and pronotum as in baumanni except pronotal punctures slightly larger and closer. Pronotum 0.83 times as long as wide.

Elytra 1.2 times as long as wide, 1.5 times as long as pronotum; outline and basal crenulations as in baumanni; striae feebly impressed, punctures very coarse, deep, decreasing in size slightly toward base; interstriae distinctly narrower than striae on posterior half of dise, about equal in width on basal third, surface smooth, punctures fine, not at all crenulate, undulations feeble. Declivity essentially as in baumanni except interstriae 2 narrower, almost obsolete below. Vestiture as in baumanni except scales apparently more numerous and more widely distributed.

Female.-Similar to male except frons convex, more coarsely granulate, foveate at center with median carina extending from fovea to epistoma; interstriae 2 to 4 undulating, with an occasional weak crenulation; declivity as in female baumanni, interstriae 2 not constricted.

## Distribution.- Central California.

USA: California: Cedar Ridge in Alameda Co., 22-III51, Cupressus sargentii; Cooks Springs, C. sargentii; Livermore, 16428, C. sargentii, F. H. Herbert, Middletown, 2 -IV-50. C. sargentii; Mt. St. Helena, $20-\mathrm{X}-23, \mathrm{C}$.
sargentii.

Host.- Cupressus sargentii.
Brology.- Except for the host relationship nothing has been recorded. The lower end of the gallery includes a unique J -shaped hook (Bright 1973:135).

Notes.- The above description was prepared from 81 specimens that included 37 paratypes.

## 11. Phloeosinus sequoiae Hopkins <br> Fig. 95

Phloeosinus sequoiae Hopkins, 1903, U.S. Bur. For. Bull. 38:33 (Holotype, female; Sonoma Co., California; U.S. Nat. Mus., 55408)

Phlocosinus squamosus Blackman, 1942 (nec. Schedl 1942), Proc. U.S. Nat. Mus. 92:448 (Holotype, male; Naselle, Washington; U.S. Nat. Mus., 55409) Wood, 1957, Canadian Ent. 89:400. Synonymy
Phlocosinus blackmani Schedl, 1950, Occ. Pap. Bishop Mus. 20:36 (Replacement for squamosus Blackman); Wood, 1957, Canadian Ent. 89:400. Synonymy
Diagnosis.- This species is rather closely related to cristatus (LeConte), from which it is easily distinguished by characters summarized in the above key.

Male.- Length $3.0-4.3 \mathrm{~mm}, 2.0$ times as long as wide; color very dark brown to black, elytra usually lighter, reddish brown.
Frons transversely, subconcavely impressed in central area; median carina indicated only by a feebly raised line in deepest part of impressed area; surface shining, punctures coarse, close laterally, sparse elsewhere; vestiture hairlike, fine, inconspicuous.

Pronotum 0.89 times as long as wide; sides on basal third almost straight and parallel, then arcuately rounded to moderate constriction just behind broadly rounded anterior margin; surface smooth, shining, punctures close, deep, usually separated by distances equal to about half diameter of a puncture, some interspaces on posterior half marked by minute points; part of median line near center impunctate; vestiture hairlike, fine, short, inconspicuous.

Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; outline and basal margins as in cupressi; striae narrowly impressed, punctures obscure, weakly impressed; interstriae three times as wide as striae, shining, punctures fine, confused, usually with anterior margins at least slightly elevated, commonly with transverse lines (much deeper
and more numerous in specimens from northern part of distribution). Declivity steep, convex; striae not impressed, punctures moderately deep, distinct; interstriae 1 and 2 rather narrow, entirely unarmed, 3 elevated and armed by 8 to 12 very coarse, blunt, often laterally compressed (below) teeth (some small teeth often intermixed), 4 unarmed, 5 to 9 usually bearing three to five smaller teeth. Vestiture minute, delicate, usually abraded; sparse, hairlike on disc, declivity with minute, declicate, scales, each about twice as long as wide; specimens from northern part of range more commonly retain vestiture.

Female.- Similar to male except frontal impression greatly reduced, carina higher, reaching epistoma; interstrial punctures minutely (southern) to moderately (northern) crenulate on 2 and 3, less commonly crenulate on 1 and 4; declivital teeth slightly smaller; interstriae 1 at least partly armed by a row of fine tubercles.

Distribution.- Alaska to California.
ALASKA: Kell Bay, Kuiu 1sland. CANADA: British Columbia: Bear Hill, Blue River, Brower, Genoa Bay near Duncan, Pender Harbor, Sidney, Stanley N. P.. Tofino, Vancouver, Victoria. USA: California: Alameda Co., Berkeley, Big Sur, Carmel, Del Monte, Duncan Mills, Eureka, Fieldbrook, Gasquet, Guerneyville, Lagunitas in Marin Co., Los Gatos, Marin Co., Mill Valley, Muir Woods, Oakland, Palo Alto, Piercy, San Mateo, Santa Clara, Santa Cruz Beach, Sonoma Co., Sylvania, Taylorville, Woodside. Oregon: Brookings, Coquelle, Douglas Co., Elk Lake in Santiam N. F., Marshfield, Oak Ridge. Washington: Blaine, Hoquiam, London, Naselle, Seattle.
Hosts.- Chamaecyparis lawsoniana, Ch. nootkatensis, Cupressus macrocarpa, Libocedrus decurrens, Sequoia sempervirens, Thuia plicata.

Notes.- The above descriptions were based on the holotypes of sequoiae and squamosus and on 467 other specimens.

Blackman (1942) divided this taxon into two species on the basis of more abundant and larger female declivital scales, and more abundant female punctures on the declivity. Specimens from redwood in northern California have the declivital scales just as abundant and as large as do specimens from northern localities from other hosts. I see no difference in the number of punctures from the two areas, although those on specimens from the northern areas are distinctly larger. It

21

male, mandibles omitted: 28, furnissi, maxe, male; 23, taxodii, female; 24, dentatus, male; 25, serratus, male; 26, scopulorum nomexicamus, male. 27 , sequoiac,
appears that slight clinal differences do exist in the coarseness of the declivital punctures and vestiture and in the sculpture of the discal interstriae in both sexes; however, based on the material at hand, these changes apparently are not related to the host nor is the transition sufficiently abrupt to permit recognition of geographical races.

## 12. Phlocosinus cristatus (LeConte) Figs. $22 \mathrm{C}, 95,96$

Hylesinus cristatus LeConte, 1868, Trans. American Ent. Soc. 2:169. 170 (California; Carnegie Mus.) Phlocosimus chiricahua Blackman, I942, Proc. U.S. Nat. Mus. 92:444 (Holotype, male; Chiricahua Nat Mon., Cochise Co., Arizona; U.S. Nat. Mus., 55400); Wood, 1971, Great Basin Nat. 31:147. Synonymy
Diagnosis.- This species is very closely related to sequoiae Hopkins, from which it is distinguished by characters summarized in the above key.

Male.- Length 2.8-4.0 mm, 2.0 times as long as wide; color very dark brown, elytra usually lighter.

Frontal cavity slightly deeper and narrower than sequoiae, carina reaching epistoma; lateral and dorsal areas more coarsely granulate.

Pronotum 0.88 times as long as wide; as in sequoiae.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; outline, basal margins, and striae as in sequoiae; interstriae two to three times as wide as striae, punctures transversely, densely subcrenulate (northern) to rather closely rippled to strongly undulate (southern). Declivity as in sequoiae except upper margin of interstriae 1 usually armed by two or three small granules, 1 and 2 usually more closely, deeply punctured, scalelike vestiture longer, much more abundant, distributed over entire declivity.

Female.- Similar to female sequoiae except frons with rather abundant, isolated granules; interstrial crenulations on dise higher; teeth on declivital interstriae 1 larger and more regularly placed; interstrial punctures on declivity larger and more abundant; scalelike vestiture on declivity larger, more abundant, and more widely distributed, reaching middle of disc in some specimens.

Distribution.- California to Arizona and Durango.

USA: Arizona: Chiricahua Mts., Douglas, Gila Valley, Globe, Nogales, Oak Creek Canyon, Phoenix, Safford, Santa Catlaina Mts.. Sedonia, Thatcher, Tuscon. California: Carlotta, Contra Costa, Fresno, Glendale, Kings Co., Lockwood, Los Angeles, Martinez, Newhall, North Hollywood, North Sacramento, Oakland, Oroville, Palo Alto, Paradise Springs. Placerville, Reedley, Rio Linda, Sacramento, San Diego, San Jose, Santa Ana Canyon, Santa Rosa, Sonoma, Vine Hill in Contra Costa Co. MEXICO: Durango: Los Altos. Sonora: Cucuta.

Hosts.- Cupressus arizonica, C. forbsei, C. macrocarpa, Juniperus sp., Thuia sp.

Brology. - This species attacks the lower bole and evidently the larger limbs of the host tree, where galleries similar to those described for the genus are cut. Primary attacks that killed healthy cypress trees have been attributed to this species. The young adults normally construct maturation feeding tunnels in the pith of small, healthy twigs of living trees before seeking a new host.

Notes. - The above descriptions are based on the holotype of chiricalua, on the series of cristatus studied by Hopkins and Blackman, and on 198 other specimens.

Blackman (1942) divided this taxon into two species based on differences in the sculpture of the discal interstriae, on the impression of the sutural striae on the declivity, and on the vestiture. The material at hand was the character of the discal interstriae, the reverse of that reported by Blackman; the second and third characters I am unable to detect. The differences in sculpture of the interstriae are so slight and variable I do not feel separate species or even geographical races can be recognized from the material presently available for study. Until more data are available that will support their separation, I prefer to recognize only one species.

It is noted with interest that material of sequoiae from the northern part of its distribution (Oregon to British Columbia) resembles cristatus from Arizona much more closely than do specimens of these species from the zone of overlap in their distributions.

## 13. Phloeosinus scopulorum scopulorum Swaine

Phloeosinus scopulorum Swaine, 1924, Canadian Ent. 56:148 (Holotype, male; Williams Lake, British Columbia; Canadian Nat. Coll.)
Diagnosis.- Superficially this species resembles serratus (LeConte), with which it is
easily confused, but it is distinguished by the more deeply impressed male frons, by the more finely sculptured discal interstriae, by the complete absence of tubercles on declivital interstriae 2, and by the smaller declivital teeth.

Male.- Length $2.4-4.0 \mathrm{~mm}, 2.0$ times as long as wide; color very dark brown to black, elytra reddish brown.

Frons narrowly, shallowly concave on lower two-thirds; median carina represented only by an epistomal tubercle; shining, punctures coarse, rather close laterally, rather sparse in concavity and above, rarely with two or three minute tubercles above; vestiture hairlike, fine, short, inconspicuous.

Pronotum 0.87 times as long as wide; widest near base, sides arcuately convergent to moderate constriction just before broadly rounded anterior margin; surface smooth with rather sparse, minute points, punctures coarse, separated in central area by distances equal to diameter of a puncture; vestiture short, hairlike, inconspicuous.

Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind, posterior outline interrupted by declivital teeth; basal margins each armed by 9 or 10 crenulations; striae weakly impressed, punctures moderately large, obscurely impressed; interstriae twice as wide as striae, 2 and 3 with small, isolated, short crenulations, others feebly, more sparsely crenulate. Declivity steep, convex; interstriae 2 impressed, unarmed, finely punctured, 1 and 3 moderately elevated, 1 armed by six, 3 by seven or eight moderately large, recurved, stout teeth, those near middle on 1 strongly compressed laterally, 5,7 , and 9 each bearing two or three smaller teeth. Vestiture consisting of fine and stout hairlike setae intermixed, stout setae predominant on declivity.

Female.- Similar to male except frons convex, marked on lower half by a fine, median carina, surface more closely punctured, bearing rather numerous, fine granules; crenulations on discal interstriae higher; teeth on declivital interstriae smaller, conical, pointed, almost twice as numerous; declivital vestiture scalelike, much more abundant.

Distribution.- British Columbia and Alberta to Washington.
CANADA: Alberta: Lethbridge, $15-\mathrm{V}-30$, J. H. Pepper. British Columbia: Canyon House, 14-VII-22, Juniperus scopulorum. R. Hopping; Creston, 9-V-58, H. Howden; Boswell, $9-\mathrm{V}-58$. H. Howden; Lumby in Creighton Valley, 30-VIII-32, Thuia plicata, R. Hopping; Pavilion Lake, 8-VIII-72, J. scopulorum, D. E. Bright; Salmon Arm, $10-\mathrm{V}-32$, H. B. Leech; Williams Lake, 21 -VIII-21, J. scopulorum, R. Hopping; Wyndel, 15-V-58, H. Howden. USA: Washington: Vantage Bridge, 20-II35, J. scopulorum, J. A. Beal.

Host.- Juniperus scopulorum.
Biology.- Except for the host association and gallery (Bright 1976:216) nothing has been published.

Notes. - The above description was prepared from the holotype and 138 other specimens.
14. Phloeosinus $\begin{array}{ll}\text { scopulorum neomexicanus } \\ \text { Blackman }\end{array}$

Fig. 95
Phloeosinus neomexicanus Blackman, 1942, Proc. U.S. Nat. Mus. 92:460 (Holotype, male; Vermejo, New Mexico; U.S. Nat. Mus., 55412)
Phloeosinus texanus Blackman, 1942. Proc. U.S. Nat. 92:462 (Holotype, male; Montell, Uvalde Co., Texas; U.S. Nat. Mus., 55-113); Wood, 1971, Great Basin Nat. 31:149. Synonymy
Diagnosis. - This subspecies is probably recognizable only because of the lack of material from Idaho; it is distinguished from $s$. scopulorum Swaine by the more finely, more closely punctured frons and pronotum, by the very slightly, more coarsely sculptured discal interstriae, and by the longer male carina extending from epistoma to fundus of impression.

Male.- Length 2.2-3.7 mm, 1.93 times as long as wide; color very dark brown to black, elytra reddish brown.
Except as noted in the diagnosis above, I am unable to distinguish these races.

Female.- See s. scopulorum above.
Distribution.-S Idaho to Texas.
USA: Arizona: Chiricahua Mts., Lakeside, Santa Catalina Mts., Santa Rita Mts. Colorado: El Paso Co., Ft. Garland, Mesa Verde N. P., Ute Pass. Idaho: Franklin. Montana: Columbia Falls. Nevada: Charleston. New Mexico: Bandelier, Capitan, Vermejo. Texas: Austin, Dallas, Gillespie, Grundyville, Montell, San Antonio, Sonora. Utah: Beaver, Kamas, Logan, Logan Dry Canyon,
Oak Creek Canyon, Panguitch Oak Creek Canyon, Panguitch, Zion N. P.

Hosts.-Cupressus arizonica, Juniperus deppeana, J. monosperma, and J. osteosperma.

Brology.- This is perhaps the most common Phloeosinus in Utah. It attacks cut or injured limbs and bole of the host trees. The gallery system is as described for the genus. The maturation twig-feeding habit has not been observed.

Notes. - The above treatment was based on the holotype and on 188 other specimens.

The validity of this subspecies is questioned. When more material from Idaho and neighboring areas is available, the slight differences that characterize it are almost certain to intergrade with those of $s$. scopulorum.

## 15. Phlocosinus punctatus LeConte Figs. 94, 96

Phlocosinus punctatus LeConte, 1876, Proc. American Philos. Soc. 15:382 (Lectotype, female; Oregon; Mus. Comp. Zool., 978, present designation)
Phlocosimus rubicundulus Swaine, 1924, Canadian Ent. 56:144 (Holotype, female; Hossack Meadow, Tulare Co., California; Canadian Nat. Coll., 729); Wood 1971, Great Basin Nat. 31:149. Synonymy Phloeosinus buckhorni Blackman, 1942, Proc. U.S. Nat. Mus. 92:432 (Holotype, male; Portland, Oregon; U.S. Nat. Mus., 55403 ); Wood, 1966, Great Basin Nat. 26:27. Synonymy
Phlocosinus kaniksu Blackman, 1942, Proc. U.S. Nat. Mus. 92:434 (Holotype, male; Metaline Falls, Washington; U.S. Nat. Mus., 55404); Wood, 1966, Great Basin Nat. 26:27. Synonymy
Phloeosinus rusti Blackman, 1942, Proc. U.S. Nat. Mus. 92:435 (Holotype, male; Metaline Falls, Washington; U.S. Nat. Mus., 55405 ); Wood, 1966, Great Basin Nat. 26:27. Synonymy
Phloeosinus chamberlini Blackman, 1942, Proc. U.S. Nat. Mus. 92:470 (Holotype, male; Alturas, California; U.S. Nat. Mus., 55415); Wood, 1971, Great Basin Nat. 31:149. Synonymy
Diagnosis.- This species is distinguished from $s$. scopulorum Swaine by the much wider striae, by the more finely sculptured discal interstriae, by the bright, shining elytral surfaces, and by the much finer, usually abraded elytral vestiture.

Male.- Length 1.9-3.4 mm, 1.9 times as long as wide; color very dark brown to black, elytra reddish brown.

Frons rather deeply concave on median half from upper level of eyes to epistoma; epistoma armed by a median tubercle, no other remnant of carina visible; surface shining, rather coarsely, closely punctured, with rather abundant, isolated granules to epistoma; vestiture hairlike, fine, inconspicuous.

Pronotum 0.88 times as long as wide; as in s. scopulorum.

Elytra 1.3 times as long as wide, 1.6 times as long as pronotum; outline and basal margins as in s. scopulorum; striae impressed, punctures large, confluent, obscurely impressed; interstriae about as wide as striae, shining, punctures moderately large, almost uniseriate, most with anterior margin slightly elevated but not at all granulate. Declivity steep, convex; striae much narrower than on disc; interstriae 2 as wide as 1 or 3 , unarmed, shining, a few minute, obsolescent punctures usually present, 1 and 3 moderately elevated and armed by about six coarse teeth on 1 , by about seven on 3, each tooth recurved, conical, rarely slightly compressed laterally on 1 ; interstriae 5,7 , and 9 each with one to three smaller teeth; entire surface brightly shining, interstrial punctures reduced in size and number over entire surface. Vestiture usually abraded; when present it consists of sparse, short, fine, hairlike setae on disc, often becoming rather stout on declivity.

Female.- Similar to male except frons convex, a median fovea at center, median carina extending from fovea to epistomal margin, granules somewhat larger; anterior margins of interstrial punctures suberenulate; declivital teeth slightly smaller and more numerous (about eight on 1, 10 on 3); vestiture on declivity, when present, includes scales at least on interstriae 1 and 3 .

Distribution.-S Alaska and N Idaho to California and E Nevada.

Alaska: Hollis, Petersburg. Canada: British Columbia: Blue River, Bowser, Chase, Likely, Lumby in Creighton Valley, Pender Harbor, Princeton, Stanley N. P., Steelhead, Trinity Valley, Vancouver, Vernon. USA: California: Alturas, Camp Seely in San Bernardino Co., Carrville, Cascada, Chester, Daulton Meadow, Facht in Lassen Co., Fallen Leaf Lake, Faunskin, Forest Hill in Placer Co., Hat Creek, Hazel Green in Mariposa Co., Hossock Meadow in Tulare Co., Huckleberry Meadow in Fresno Co., Lassen N. P., Mariposa Co., McCloud, Meadow Valley in Plumas Co., Miami R. S. in Madera Co., Mill Creek in Tuolumne Co., Mt. Palomar, Norval Flats in Lassen Co., Pine Crest, Placer Co., Placerville, Pyramid R. S., Sequoia N. P., Shasta Springs, Sierra N. F. in Fresno Co., Siskiyou Co., Sugar Pine, Weed, Yosemite Valley. Idaho: Kamiah, Moscow. Nevada: Reno. Oregon: Brandon, Coos Bay, Corvallis, Florence, Klamath Lake, Lolo Pass in Clackamas Co., Marshfield, Prineville, Redmond, Santiam N. F., Taft, Tolo. Washington: Easton, Metaline Falls, Mt. Rainier, Northbend in King Co., Northport, Wind River.

Hosts.- Chamaecyparis nootkatensis, Juniperus occidentalis, Libocedrus decurrens, Sequoia gigantea, S. sempervirons, Thuja occidentalis, T. plicata, Tsuga heterophylla.

Biology.- This is the most common Phloeosinus on the Pacific Coast. It attacks from the bole to the small limbs of its host, usually in cut or injured material, although primary attacks have been attributed to it. The tunnels are essentially as described for the genus.
Notes. - The above description was based on three syntypes of punctatus, on the holotypes of rubicundulus, buckhorni, kaniksu, rusti, and chamberlini, and on more than 800 other specimens. Blackman's (1942) rugosus is this species.

This species is somewhat variable, particu= larly with respect to the details in sculpture of the male frons and the declivital vestiture. The latter character apparently is related more to beetle activity and moisture factors than to distribution or genetics. As a result, six synonyms have been described by Swaine and Blackman. The types and several paratypes of each of the synonyms were studied and compared to long series from adjacent localities. Because nothing more than minor variations that should be expected in a long series are represented, only one species is recognized here. LeConte's original series of punctatus was composite (Blackman 1942). The first of three female syntypes from Oregon is here designated as the lectotype of punctatus.

## 16. Phloeosinus vandykci Swaine

Phlocosinus vandykei Swaine, 1915, Canadian Ent. 47:366 (Lectotype, female; Millwood, Fresno Co., California; Canadian Nat. Coll., designated by Bright, 1967, Canadian Ent. 99:677)
Phlocosinus russus Swaine, 1924, Canadian Ent. 56:148 (Holotype, female; San Bernardino Mountains, California; Canadian Nat. Coll.); Blackman, 1942, Proc. U.S. Nat. Mus. 92:425. Synonymy
Diagnosis.- Although allied to punctatus LeConte and fulgens Swaine, this species is not closely related. It is easily distinguished by the bright, shining surfaces, by the fine sculpturing, and by other characters summarized in the above key.

Male.-Length $1.8-2.2 \mathrm{~mm}, 2.0$ times as long as wide; color dark brown to black, elytra reddish brown.

Frons rather broadly concave from upper level of eyes to epistoma, a moderately large, median tubercle on epistoma but no other evidence of a carina; surface shining, punctures rather coarse, moderately close, most of them very finely granulate; vestiture hairlike, fine, inconspicuous.

Pronotum 0.83 times as long as wide: otherwise as in punctatus.

Elytra 1.4 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; basal margins each armed by $10-11$ crenulations; striae narrowly impressed, punctures moderately large, obscurely impressed; interstriae about twice as wide as striae, punctures moderately large, uniseriate except somewhat confused on basal two-thirds of 2 and 3, anterior margins of most punctures toward base elevated. Declivity steep, convex; striae not impressed, punctures appearing coarse (partly due to coloration); interstriae smooth, with minute points, 1 and 3 very feebly elevated, 1, 3, 5, 7 , and 9 each with about two to six minute tubercles. Vestiture very sparse, when present consisting of a few minute, hairlike bristles.

Female. - Similar to male except frons convex, a carina feebly indicated above tubercle; discal interstriae 1 to 3 finely subcrenulate; declivital tubercles tending to be
slightly slightly more numerous.

Distribution.-S Oregon to California.
USA: California: Blodgett Forest near Georgetown in El Dorado Co., Camp Seely, Carrville, Castle Craig, Chiquito Basin, Dardanelles in Tuolumne Co, El Dorado Co.. Fallen Leaf Lake, Fish Camp in Mariposa Co., Forest Hill, Fresno, General Grant N. P., Grass Valley, Hazel Green, Huckleberry Meadow in Fresno Co., Lake Arrowhead, Lost Lake, Mariposa Co., Miami R. S. in Mariposa Co., Millwood, Mt. Shasta, North Fork, Patterson Mtn. in Fresno Co., Placer Co., Placerville, Sand Flat, Sierra N. F. in Fresno Co., Strawberry in Tuolumne Co., Yosemite N. P. Oregon: Klamath Falls, Pinehurst.

Host.-Libocedrus decurrens.
Brology.- This species breeds in branches of the host; the gallery system evidently is
similar to that described for similar to that described for the genus.
Notes. - The above description was based on the lectotype of vandykei, on the holotype of russus, and on 362 other specimens.

## 17. Phloeosinus fulgens Swaine

Figs. 94, 96

Phloeosinus fulgens Swaine, 1924, Canadian Ent. 56:146 (Holotype, male; Northfork, California; Canadian Nat. Coll.)
Phloeosinus splendens Blackman, 1942, Proc. U.S. Nat. Mus. 92:428 (Holotype, male; Pinehurst, Oregon, U.S. Nat. Mus., 55402); Wood, 1971, Great Basin Nat. 31:148. Synonymy
Diagnosis.- This species is allied to vandykei Swaine, but it is easily distinguished by the larger size, by the coarsely, very closely punctured pronotum, and by the more strongly elevated, alternate declivital interstriae.

Male.- Length $2.0-2.7 \mathrm{~mm}, 2.1$ times as long as wide; color very dark brown, elytra usually a lighter brown.

Frons rather narrowly concave below upper level of eyes; surface shining, coarsely, closely punctured, a few small granules on dorsolateral margin of concavity; carina represented by a median, submarginal subtuberculate callosity; vestiture consisting of fine, rather abundant, moderately long, inconspicuous hair.

Pronotum 0.88 times as long as wide; as in scopulorum except punctures much coarser and closer, interspaces usually less than a fourth as wide as diameter of a puncture; glabrous, except at margins.

Elytra 1.3 times as long as wide, 1.6 times as long as pronotum; outline as in vandykei; basal margins each armed by 12-13 crenulations; striae narrowly impressed, punctures obscurely impressed; interstriae two to three times as wide as striae, coarsely, very closely, somewhat irregularly punctured, interspaces between punctures often narrowly rounded but not at all crenulate. Declivity steep, convex; interstriae 1 and 3 slightly elevated, 1 armed by four to six small teeth, 3 by six to nine, $5,7,8$, and 9 by two or three subtuberculate granules, 2 as wide as 1 or 3 , smooth, shining, with a few fine, obscure punctures. Vestiture consisting of minute, confused, interstrial hair on declivity; abraded in most specimens.

Female.-Similar to male except frons convex to feebly impressed, carina fine, long, extending from epistomal margin two-thirds distance to upper level of eyes; many pronotal punctures tend to be subconfluent;
tubercles on elytral declivity tend to ve smaller, interstriae 1 and 3 less strongly elevated.

Distribution.-S Oregon to California.
USA: California: El Dorado Co., Giant Forest, Grass Valley, Hackamore, Madera Co., Mill Creek in Tuolumne Co., Northfork, Oakhurst in Madera Co., Paradise Creek in Sequoia N. P., Placerville, Sequoia N. P., Wawona, Willow Ranch in Modoc Co., Yosemite. Oregon: Ashland, Wonder

## Host.-Libocedrus decurens.

Biology.- Chamberlin (1958:91) indicated dying branches in the tops of the living host were selected for attack. The longitudinal egg galleries were up to 4 cm in length and almost entirely in the bark. Larval mines began perpendicular to the parental gallery, but soon turned parallel to the grain of the wood. They engraved the wood rather deeply.

Notes.- The above descriptions were based on the holotypes of fulgens and splendens and on 141 other specimens.

## 18. Phloeosinus furnissi Blackman <br> Fig. 95

Phloeosinus furnissi Blackman, 1942, Proc. U.S. Nat. Mus. 92:169 (Holotype, male; Flagstaff, Arizona; U.S. Nat. Mus., 55414)

Diagnosis.- The above key indicated the superficial affinities of this species; it is much more likely to be confused with scopulorum neomexicanus Blackman. From s. neomexicanus it may be distinguished by the finer elytral vestiture in both sexes, by the conical noncompressed teeth on the male elytral declivity, and by the smoother discal interstriae which have finer granules.

Male.- Length $2.3-3.3 \mathrm{~mm}, 2.0$ times as long as wide; color very dark brown, elytra partly or entirely brown to reddish brown.

Frons transversely impressed on middle half, becoming shallowly concave toward center, surface smooth, shining, rather sparsely, deeply punctured, granulate on dorsolateral margin of concavity; epistomal area ascending toward margin, armed on median line by a fine, somewhat indefinite tubercle; vestiture fine, hairlike, inconspicuous.
Pronotum 0.82 times as long as wide; as in s. neomexicanus except punctures tending to be slightly larger and more widely spaced, interspacial impressed points more conspicuous; vestiture fine, hairlike, of moderate length and abundance.

Fig. 96. Gallery systems: 10, Alniphagus aspericollis; 11, Phlocosinus fulgens; 12, Phlocosinus punctatus; 13, Phloeosinus variolatus; 14, Phloeosinus cupressi; 15, Phloeosinus cristatus; 16, Chaetophloeus heterodoxus; 17, Cacto-
pinus desertus; 18, pinus desertus; 18, Cactopinus rhois. (After Bright and Stark 1973:135.)

Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind, declivital profile interrupted by projecting teeth; basal margins each armed by 10 crenulations; striae narrowly impressed, punctures rather obscurely indicated; interstriae three times as wide as striae, smooth and shining, tuberculate, short crenulations small, rounded, isolated, their width averaging less than one-fourth width of interstriae. Declivity convex, steep; interstriae 1 and 3 moderately elevated, 1 armed by 5 to 9 subconical teeth, 3 by 9 to 11 similar but more nearly conical teeth, 5, 7 and 9 each with 3 to 5 smaller teeth. Vestiture moderately abundant on disc and declivity, mostly hairlike, a few setae on disc laterally compressed, many of those on declivity stout, very narrowly scalelike.
Female.- Similar to male except frons convex, a carina usually not indicated; crenulations on discal interstriae higher and slightly wider; declivital vestiture more abundant, particularly scales, each scale very slender, at least six to eight times as long as wide, scales much more slender, at least six to eight times as long as wide, scales much more slender and much more abundant than in $s$. neomexicanus.

Distribution.-SW Wyoming to Arizona and New Mexico.

USA: Arizona: Bear Canyon in Santa Catalina Mts., Flagstaff, Jerome. Colorado: Míesa Verde N. P. New Mexico: Nogal. Utah: Beaver, Boulder, Manila, St. George. Wyoming: Ft. Bridger.

Hosts.- Juniperus deppeana, J. monosperma, J. osteosperma.

Habits. - This species attacks the larger limbs and branches of the host tree, where gallery systems similar to those described for the genus are constructed.

Notes. - The above descriptions were based on the holotype and on 108 other specimens.

## 19. Phloeosinus canadensis Swaine

Phlocosimus eanadensis Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):8 (Lectotype, female; St. Ame de Bellevue, Quebec, Canada: Canadian Nat. Coll., designated by Bright. 1967, Canadian Ent. 99:676)
Diagnosis.- This species is rather closely allied to furnissi Blackman, from which it is
distinguished by characters summarized in the above key.

Male.- Length $2.0-2.9 \mathrm{~mm}, 1.9$ times as long as wide; color rather dark brown, elytra a lighter brown.

Frons very shallowly concave between upper level of eyes and epistomal margin; surface smooth, shining, rather sparsely, coarsely, deeply punctured, devoid of granules; median carina finely, acutely elevated on lower half; vestiture fine, rather abundant.

Pronotum 0.86 times as long as wide; essentially as in furnissi except sides less strongly arcuate, with punctures slightly smaller, closer, and interspacial points largely obsolete or contributing toward obscure reticulation; vestiture fine, rather abundant.

Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; outline as in furnissi; basal margins each armed by 11 crenulations; striae and interstriae as in furnissi except punctures on posterior slopes of crenulations more conspicuous, crenulations evidently very slightly higher. Declivity as in furnissi except teeth on interstriae 1 not at all laterally compressed. Vestiture rather abundant; some setae on disc laterally compressed, some on declivity rather stout.

Female.-Similar to male except frons convex with most punctures in lateral areas finely granulate; crenulations on discal interstriae higher, wider and evidently more numerous; declivital teeth finer; declivital vestiture mostly stout but not actually scalelike.

Distribution. - Ontario and New Brunswick to Minnesota and New York.

CANADA: New Brunswick: Fredicton, McGraw Brook, Pisquit Brook, Plaster Rock. Ontario: Bancroft, Carp, Constance Bay, Frater, Lake of the Woods, MacDiarmid, Toronto. Quebec: Chelsea, Ft. Coulonge, Hull, Laniel, St. Anne de Bellevue. USA: Maine: Beaver Pond, Brunswick, Meddybemps, Monson, Orono. Michigan: Grand Island, Mackinac Island, Marquette. Minnesota: Itasca Park. New Hampshire: Milford. New York: Arton, Clear Lake, Flood Wood, Rensselaer, Schroon, Syracuse. Ohio: Columbus.

## Host.- Thuja occidentalis.

Brology. - The tunnels were constructed in bole, limbs, and branches of the host and evidently were similar to those described for the genus.

Notes. - Swaine designated a female type by a label in his original series of four specimens, but neglected to mention the designation in the original publication of the name.

As indicated above, Bright designated this specimen as lectotype for the species. The above descriptions were based on four lectohomotypes from Frater. In all, 884 specimens were examined.

## 20. Phloeosinus hoppingi Swaine

Phlooosinus hoppingi Swaine, 1915. Canadian Ent. 47:364 (Lectotype, female; Camp 6, California: Canadian Nat. Coll, designated by Bright, 1967,
Canadian Ent. 99.676 ) Canadian Ent. 99:676)
Phlocosinus woodi Bright, 1966, Pan-Pacific Ent. 42:296 (Holotype, male; Cypress Camp, near Hat Creek. Shasta Co., California; Wood Coll.); Wood, 1971, Great Basin Nat. 31:149. Synonymy
Diagnosis. - This species, at least superficially, resembles hoferi Blackman much more closely than it does any species placed near it in the above key. However, the relationship to hoferi is not close. It differs from hoferi by the long, well-developed frontal carina, by the much more coarsely tuberculate discal interstriae, and by the different declivital vestiture.

Male.- Length 1.7-2.2 mm, 1.97 times as long as wide; color very dark brown to black, elytra, at least partly, lighter brown.

Frons concave from upper level of eyes to epistoma, deeper on upper half of impression; surface smooth, shining, rather finely, closely punctured; an acutely elevated median carina on lower two-thirds; vestiture fine, hairlike, rather abundant.

Pronotum 0.80 times as long as wide; sides very weakly arcuate and converging slightly on basal half then abruptly rounded to constriction just behind broadly rounded anterior margin; surface shining, coarsely, deeply punctured, fine impressed points moderately abundant; vestiture fine, hairlike, moderately abundant.

Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; outline about as in furnissi; basal margins each armed by 10 crenulations; striae impressed, punctures obscurely indicated; interstriae one and one-half to two times as wide as striae, convex, punctures coarse, confused, their anterior margins slightly elevated, some forming low, rounded nodules in uniseriate rows. Declivity steep, convex; interstriae 1 and 3 rather strongly elevated and armed by coarse, stout teeth, those on 1 slightly larger, 1 bearing 10 to 12 , 3 bearing 11 to $13,5,7$, and 9 each bearing 4
or 5 smaller teeth, 2 narrowed apically, narrower than 1 or 3 , punctured. Vestiture consisting of rather abundant, fine, and laterally compressed hairlike setae intermixed on disc, becoming predominately scalelike on declivity; each scale on interstriae 2 about three times as long as wide, more slender elsewhere.

Female. - Similar to male except frons convex and more nearly granulate; interstrial granules on disc slightly larger; declivital teeth slightly smaller (much coarser than in most females of this genus); stouter declivital scales more widely distributed.

Distribution. - British Columbia to California.

CANADA: British Columbia: Canyon House. USA: California: Alta Sierra in Kern Co., Bass Lake, Barkhouse in Siskiyou Co., Burney, Fallen Leaf Lake, Fawnskin, Fresno Co., General Grant N. P., Ciant Forest, Hat Creek, Lake Eiler in Lassen N. F., Last Chance Creek near Milford, McCloud, Miami R. S., Millwood, Modoc Co., Monterey, Mt. St. Helena, Northfork, Pinecrest, Sequoia N. P., Tahoe City, Viola, Wawona, Yosemite.

Hosts. - Cupressus macnabiana, C. macrocarpa, C. sargentii, Juniperus occidentalis, J. scopulorum, Libocedrus decurrens.

Biology.- Twigs or branches less than 4 cm in diameter are usually selected for attack. The gallery pattern evidently is similar to that described for the genus.

Notes. - The above descriptions were based on the lectotype of hoppingi, on the type series of woodi, and on 275 other specimens.

## 21. Phloeosinus setosus Bruck

Phloeosinus setosus Bruck, 1933, Canadian Ent. 65:54 (Holotype, male, Mount Saint Helena, Napa Co., California: Ohio State Univ. Coll.)
Diagnosis. - This species is very closely related to arizonicus Blackman, but it is distinguished by characters summarized in the above key.

Male.- Length $1.7-2.4 \mathrm{~mm}, 1.8$ times as long as wide; color very dark brown, elytra lighter brown.

Frons shallowly, subconcavely impressed just below upper level of eyes; an acutely elevated carina extending from deepest point in impression to epistomal margin; surface shining, punctured above upper level of eyes, with moderately abundant, isolated, rather coarse granules below to epistoma; vestiture
consisting of fine, inconspicuous, hairlike setae of moderate length.

Pronotum 0.80 times as long as wide; widest at base, sides arcuately converging to prominent constriction just before broadly rounded anterior margin; surface shining, punctures moderately large, separated in some areas by distances as great as diameter of a puncture, interspaces marked by rather abundant points (one male has some of punctures very finely asperate, probably an abnormality); vestiture of fine, short, moderately abundant hair.

Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind, declivital teeth interrupting profile; basal margins each armed by 10 crenulations; striae narrowly impressed, punctures obscurely indicated at margins; interstriae slightly wider than striae, shining, uniseriately armed by a row of narrow, rather high crenulations, a setiferous puncture on posterior slope of each. Declivity convex, steep; striae less strongly impressed and evidently narrower than on disc; interstriae 1 and 3 slightly elevated and armed by a row of small teeth, those on 3 slightly larger, 5 to 9 each armed by one to four small teeth, 2 smooth, marked by fine points, as wide as 1 or 3 . Vestiture consisting of fine strial hair and, on disc, uniseriate rows of laterally compressed, semitransparent scales, scales on declivity more abundant, particularly on 1 and 3,2 glabrous on declivity; each scale on disc onehalf to two-thirds as long as distance between rows, about six times as long as wide; each scale on declivity shorter, stouter, rather abundant on 1 .

Female.- Similar to male except frons convex, devoid of granules, punctured to epistoma; discal crenulations larger, closer, staggered; declivital striae wider, interstriae 2 slightly narrower than 1 or 3 ; vestiture slightly longer.

Distribution.- Napa and Colusa Counties, California.

USA: California: Cook's Springs in Colusa Co., 26-X7I, Cupressus sargentii, H. B. Leech: Mt. St. Helena, 29-III-30, 2I, 26-III-31, I5-XI-3I, C. sargentii, C. R. Bruck, etc.

Host.- Cupressus sargentii.
Brology.- Reared from branches of the above host.

Notes.- The above descriptions were based on the holotype, allotype, and 33 paratypes, and on 302 other specimens.

## 22. Phlocosinus arizonicus Blackman

Fig. 94
Phloeosinus arizonicus Blackman, I942, Proc. U.S. Nat. Mus. 92:424 Holotype, male: Santa Catalina Mountains, Arizona; U.S. Nat. Mus., 5540I)
Diagnosis.- This species is very closely related to setosus Bruck, from which it may be distinguished by characters summarized in the above key.

Male.- Length $1.8-2.3 \mathrm{~mm}, 1.88$ times as long as wide; color very dark brown, elytra a lighter brown.

Frons and pronotum as in setosus.
Elytra as in setosus except discal striae less strongly, more narrowly impressed; declivital striae narrowly impressed, individual punctures very obscure.

Female.- Differs from male in same ways as in setosus, except declivital striae and interstriae as in male.

Distribution.- Arizona.
USA: Arizona: Chiricahua Mts., Hopk. U.S. 5555, Cupressus arizonica, J. L. Webb; Pine, II-X-40, Hopk. U.S. 33155A, C. arizonica, R. L. Furniss; Rucker Canyon in Chiricahua Mits., 21-VII-68, C. arizoniea, D. E. Bright: Santa Catatina Mits., I8-IV-0S, Hopk. U.S. 7193, and 5-VIII-68, C. arizonica, D. E. Bright; Sedonia, 2-VIII-62, C. arizonica, S. L. Wood.

Host. - Cupressus arizonica.
Biology. - Specimens were taken from a 25 cm bole of the host. The tunnels were essentially as described for the genus.

Notes. - The above treatment was based on the holotype and on 112 other specimens.
This species differs from setosus only in the depth and width of the striae and strial punctures, both of which vary, but do not overlap in the series at hand. It will be most surprising if additional material from California localities does not close the apparent gap in characters between these populations even to the extent of eliminating geographical races.

## 23. Phloeosinus antennatus Swaine

Phloeosinus antennatus Swaine, 1924, Canadian Ent. 56: I 46 (Holotype, male; Strawberry, California; Canadian Nat. Coll.)
Phlocosinus pseudotsugae Chamberlin, 1955, Pan-Pacific Ent. 3I:II7 (Holotype, male?; Tiller, Oregon; California Acad. Sci.); Wood, 1957, Canadian Ent. 89:400. Synonymy

Diagnosis.- This species is allied to tacubayae Hopkins and, perhaps, to hoppingi Swaine, but it may be distinguished by characters summarized in the above key.

Male.- Length $1.6-2.0 \mathrm{~mm}, 1.9$ times as long as wide; color very dark brown, elytra lighter brown.

Frons transversely impressed one-third of distance below upper level of eyes then gradually ascending to epistoma, impressed area with a long, median carina of uniformly low height; surface shining, punctate with moderately abundant, rounded, isolated granules above impression; vestiture of moderately abundant, fine, rather short hair.
Pronotum 0.80 times as long as wide, widest at base, sides on basal half feebly arcuate, very slightly converging, then abruptly rounded to constriction just behind broadly rounded anterior margin; punctures rather coarse, close, separated by distances averaging about half diameter of a puncture, interspaces smooth, shining, with a few minute points; vestiture of moderately abundant, fine, short hair.

Elytra 1.3 times as long as wide, 1.8 times as long as pronotum; outline as in setosus; basal margins each armed by 10 crenulations; striae impressed, punctures obscurely indicated; interstriae as wide as striae, each bearing an irregular row of rounded granules supplemented by fine punctures, some punctures subgranulate on their anterior margins. Declivity steep, convex, striae shallowly impressed; interstriae 1 and 3 moderately elevated and armed by 9 small teeth on 1,11 small teeth on 3 , with $5,7,8$, and 9 each bearing about 3 similar teeth, 2 narrower than 1 or 3 and finely punctured. Vestiture of both fine and stout, hairlike setae of equal length on disc; becoming rather densely scalelike on declivity, including interstriae 2 , each scale short, not more than twice as long as wide; setae on declivity arising from lower margins of teeth longer and more nearly hairlike.

Female.- Similar to male except frons convex, granules reduced; declivital teeth little, if any, smaller, scales more abundant and slightly longer.

## Distribution.- Oregon to California.

USA: California: Blodgett Forest near Georgetown in El Dorado Co., Burney, Grass Lake, in Siskiyou Co.,

Hackamore, Hat Creek. Los Angeles, Mt. Shasta, Pot Springs in Shasta Co., Siskiyou Co., Strawberry, Viola in Shasta Co., Yosemite N. P. Oregon: Corvallis, Klamath Falls, Phoenix, Pinehurst, Wapinita.

Hosts.- Libocedrus decurrens, less commonly from Cupressus sp., Pinus contorta, and Pseudotsuga taxifolia.

Biology.- This is a common species in small branches of the principal host, where it constructs tunnels similar to those described for the genus. Series were also reared from an ornamental Cupressus and from Douglas fir. One pair was taken from ground level at the base of a lodgepole pine 25 cm in diameter, where an egg gallery had been constructed, but eggs were not present; this obviously was an accidental occurrence of the species. It would appear that Chamberlin's collection of this species in Douglas fir was also a local phenomenon.

Notes. - The above description was based on the holotype and four paratypes of antennatus, on four paratypes of pseudotsugae, and on 256 other specimens.

## 24. Phloeosinus tacubayae Hopkins

Phloeosinus tacubayae Hopkins, 1905 (preprint), Proc. Ent. Soc. Washington 7:78 (Holotype, female; Tacubaya, Distrito Federal, Mexico; U.S. Nat. Mus., 7516).
Diagnosis.- This species is allied to antennatus, but it is easily distinguished by the distribution and by characters summarized in the above key.

Male.- Length $1.7-2.3 \mathrm{~mm}, 1.95$ times as long as wide; color very dark brown to black.

Frons shallowly, rather narrowly impressed on lower two-thirds, a sharply elevated, median carina extending from epistomal margin three-fourths distance to upper level of eyes; surface shining, punctures rather small, close, deep, those on upper and dorsolateral margins of impression finely granulate; vestiture fine, moderately abundant, short.
Pronotum 0.81 times as long as wide; widest about a third of length from base, sides arcuately rounded and converging to well-developed constriction just before broadly rounded anterior margin; surface shining, punctures small, deep, close, interspaces averaging less than half as great as diameter of a puncture; vestiture hairlike, stout, short, rather abundant.

Elytra 1.25 times as long as wide, 1.7 times as long as pronotum; outline as in setosus; basal margins each armed by 11 crenulations; striae narrowly impressed, punctures very obscurely indicated; interstriae twice as wide as striae, armed by confused, transversely oval, rounded granules, each granule with a setiferous puncture on posterior margin. Declivity steep, convex; striae less strongly impressed; interstriae 1 and 3 moderately elevated, 1 bearing about seven, 3 bearing nine fine teeth, 5,7 , and 9 each with about three similar teeth, 2 unarmed, narrower than 1 or 3, punctured to apex. Vestiture on dise consisting of rather sparse hairlike and slightly less abundant scalelike setae of equal length; declivital setae more abundant, entirely scalelike, each scale about twice as long as wide (more slender on 1) except median row on each interstriae about six times as long as wide, 2 clothed by scales to apex.

Female.- Similar to male except frons planoconvex; interstrial tubercles on disc higher; declivital scales longer, each about three to four times as long as wide.

Distribution.- Hidalgo to Guatemala.
MEXICO: Distrito Federal: Mexico City, 16-IX-49. Cupressus benthamii, J. P. Perry; Tacubaya, Hopk, U.S. 1144. Baumann. Hidalgo: 35 km E Tulacingo, 10-VII-67, 2300 m, No. 17, C. benthamii, S. L. Wood. Mexico: Chapultepec. VII-24, C. benthamii. GUATEMALA: Volcán de Agua, 19-V-64, 1000 m , No. 597, C. lusitanica, S. L. Wood.

Hosts.- Cupressus benthamii, C. lusitanica.

Biology.- This species was taken from the bole of a host 35 cm in diameter, and again in cut limbs about $5-10 \mathrm{~cm}$ in diameter. The tunnels appeared similar to the description given above for the genus.

Notes.- The above descriptions were prepared from my Tulacingo series. In all, 87 species were examined.

## 25. Phloeosinus swainei Bruck

Phlocosinus minutus Swaine, 1917 (nec. Blandford, 189.4), Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):9 (Lectotype, female; Fairfax, Cypress Ridge, Marin Co., California; Canadian Nat. Coll., 9252 designated by Bright, 1967, Canadian Ent. 99:677)
Phloeosinus swainei Bruck, 1933. Canadian Ent. 65:56 (Replacement name)
Diagnosis.- This species is distinguished from frontalis Bruck by the smaller punctures
on declivital striae 1 and 2 and by the hairlike declivital vestiture in both sexes; scalelike setae are entirely absent.

Male.- Length $1.5-2.1 \mathrm{~mm}, 1.8$ times as long as wide; color very dark brown to black, elytra slightly lighter.

Frons deeply, broadly concave from epistoma to just above upper level of eyes; carina reduced to an epistomal tubercle; frons shining, sparsely punctured, with small, rounded, isolated granules on upper half of lateral margins of concavity; vestiture fine, hairlike, inconspicuous.

Pronotum 0.80 times as long as wide; widest at base, sides arcuately converging to rather well-developed constriction just behind broadly rounded anterior margin; surface shining, obscurely reticulate, punctures rather coarse, deep, close, separated by distances averaging about one-half diameter of a puncture; vestiture of fine, short, moderately abundant hair.

Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind; basal margins each armed by 10 crenulations; striae impressed, small punctures individually impressed; interstriae about twice as wide as striae, each bearing a uniseriate row of narrow, moderately high tubercles and more numerous, fine, confused punctures. Declivity convex, steep; striae feebly impressed, punctures rather coarse, deep; interstriae 1 and 3 weakly elevated, 1 armed by four to five teeth, 3 by five to six teeth, all teeth on upper two-thirds, lower ones longer than distance equal to basal width, sharply pointed; interstriae 5,7 , and 8 each with about two small, toothlike granules, 2 unarmed, narrower than 1 or 3 ; all interstriae with fine, confused punctures. Vestiture consisting of coarse, flattened setae and fine hair of equal length on dise and declivity; flattened, subscalelike setae each tapered on apical half to a point, all at least six times as long as wide.

Female.-Similar to male except frons planoconvex, lower two-thirds marked by an elevated carina, granules more abundant, distributed over entire surface below upper level of eyes; discal interstrial tubercles slightly larger; declivital teeth slightly smaller and
more abundant, extending on 1 and 3 almost to apex; vestiture more abundant.

Distribution.- California.
USA: California: Alturas Co., 29-V-31, Juniperus occidentalis, Wohletz; Carson Ridge, in Marin Co.; Cypress Ridge at Fairfax in Marin Co., 5-IV-14. Cupressus sargenti, E. C. Van Dyke; Faunskin in San Bernardino Mts., 9-V-31, J. occidentalis; Modoc Co.. 8-V-31, R. L. Furniss; Mt. St. Helena, 29-II-31, A. T. McClay; Mt. Tamalpias, 26-V-29, C. sargentii, F. P. Keen; Occidental (Sonoma Co..), C. sargentii.

Host.-Cupressus sargentii and Juniperus occidentalis.

Biology. - Ecxept for the host association, nothing has been recorded pertaining to the habits of this species.
Notes. - The above descriptions are based on one male and three female paratypes and a female topotype from Fairfax, on two females from Mt. St. Helena, and on 56 other specimens. One female "paratype" from Los Angeles, Califormia, XII-14, Cupressus macrocarpa in the Canadian National collection, is not of this species.

## 26. Phloeosinus spinosus Blackman Fig. 94

Phloeosinus spinosus Blackman, 1942, Proc. U.S. Nat. Mus. 92:417 (Holotype, male; Chiricahua Mountains, "New Mexico"; U.S. Nat. Mus., 5540 )
Diagnosis.- This species is very closely related to swainei Bruck and frontalis Bruck. Typical examples are easily distinguished by characters summarized in the above key and in the following treatment.

Male.- Length 1.6-2.0 mm, 1.9 times as long as wide; color very dark brown to black, elytra slightly lighter.

Frons and pronotum as in swainei except pronotal reticulation rarely visible, usually replaced by minute points.

Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; outline, basal crenulations, and disc as in swainei; declivital sculpture and arrangement of teeth as in swainei except slender, elongate teeth on interstriae 1 about two to three times larger, those on 3 almost twice as large. Declivital vestiture consisting of abundant, short scales, each scale about twice as long as wide.

Female.- As in female swainei except frontal granules largely obsolete; declivital teeth very small; declivital scales abundant, similar to male.

Distribution. - Arizona and New Mexico to Chihuahua.
USA: Arizona: Cave Creek Canyon in Chiricahua Mts., 4 -VIII-60, Cupressus arizonica. S. L. Wood; Chiricahua N. M1., C. arizonica; Pine, II-X-40, Hopk. U.S. 33135A, C. arizonica; Santa Catalina Mts., 5-ViII-68, C. arizonica, D. E. Bright; 3 miles E Sedonia, I3-VIII-68, C. arizonica, D. E. Bright. New Mexico: Ruidoso, $8-\mathrm{X}-40$, Juniperus deppeana. R. L. Furniss. MExICO: Chihuahua: 37 km S Creel, I8-VII-60, C. arizonica, S. $L$.
Wood.
Hosts.-Cupressus arizonica, Juniperus deppeana.

Biology. - Broken or cut limbs about 10 cm in diameter were attacked by this species. The tunnels were essentially as described above for the genus.

Notes. - The above descriptions were based on the holotype and on 105 other specimens.

The Creel specimens have the male declivital teeth scarcely half as large as the Arizona material; in fact, the difference between them and the male of frontalis is slight. It appears that considerably more material from California, Arizona, and northwestern Mexico must be examined before the taxonomic status of spinosus, frontalis, and swainei can be correctly interpreted.

## 27. Phlocosinus frontalis Bruck Fig. 94

Phloeosinus frontalis Bruck, 1933, Canadian Ent. 65:55 (Holotype, male; Rialto, California; U.S. Nat. Mus., 53820 )
Phlooosinus granulatus Bruck, 1936, Southern California Acad. Sci. Bull. 35:33 (Holotype, male: Santa Ana Canyon, Orange Co., California: Ohio State Univ. Coll.): Bright, 1966, Pan Pacific Ent. 42:305. Synonymy
Diagnosis. - This species is very closely related to swainei Bruck and spinosus Blackman, but it may be distinguished, with difficulty, by characters summarized in the above key and in the following treatment.

Male.- Length $1.5-2.0 \mathrm{~mm}$, about 1.8 times as long as wide; color dark brown to black, elytra slightly lighter.

Frons as in swainei except median carina very low, extending from epistoma to deepest point in concavity. Pronotum as in swainei except reticulation obscurely visible only on anterior third.
Elytra as in swainei except declivital teeth larger, teeth almost equal to most poorly developed males of spinosus; declivital scales as
in spinosus but mostly more slender, about three to four times as long as wide.

Female.- As in female of spinosus except declivital scales tending to be more elongate, similar to those of male.

Distribution.-S California.
USA: California: Guatay in San Diego Co., I3-IX-65, Cupressus guadeloupensis, D. E. Bright: Los Angeles, XII-14, C. macrocarpa; Mt. Palomar, 26-VIII-68, Cupressus, D. E. Bright; Rialto, 2-V-30, Arizonia cypress, H. E. Burke; San Dimas, I-XII-33, C. arizonicus; Santa Ana Canyon in Orange Co., IO-XIL-30, C. forbseii. C. R. Bruck.

Host.- Cupressus forbesii, C. guadeloupensis, and C. macrocarpa.

Biology.- This species was taken from twigs and branches.

Notes.- The above descriptions were based on the holotypes of frontalis and granulatus, and on 201 other specimens.

Except for the long male carina this species is almost exactly intermediate between swaine and spinosus. Because each of these three replace one another geographically in hosts taxonomically very closely related, it is recognized that differences may reflect geographical variations in one variable species. Considerably more material from additional localities must be examined before the correct taxonomic status of these populations can be determined.

## 28. Phloeosinus keeni Blackman

Phlocosinus keeni Blackman, 1942, Proc. U.S. Nat. Mus. 92:414 (Holotype, male; Mount Rainier National Park, Washington; U.S. Nat. Mus., 55398)
Diagnosis.- This species is rather closely allied to hoferi Blackman, from which it is easily distinguished by characters summarized in the above key. Because of its distribution it might be confused with punctatus LeConte or allied species; however, the scalelike declivital vestiture and the smaller, more numerous declivital teeth distinguish keeni.

Male.- Length 2.1-2.8 mm, 2.1 times as long as wide; color very dark brown, part or all of elytra usually lighter brown.

Frons rather narrowly convex from epistoma to just above upper level of eyes, a low median carina extending from epistoma about one-half distance to deepest point of concavity; surface shining, rather closely punctured except at center of concavity,
dorsolateral margins of concavity bearing a few granules; vestiture hairlike, rather abundant, moderately long.

Pronotum 0.86 times as long as wide; sides almost straight and parallel on basal half, then arcuately converging to prominent constriction just before broadly rounded anterior margin; surface smooth, shining, punctures coarse, deep, close, interspaces marked by minute points, their widths averaging slightly less than half diameter of a puncture; vestiture consisting of fine, short, rather abundant hair.

Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds rather broadly rounded behind, profile interrupted by elevated interstriae; basal margins each armed by 11 crenulations; striae narrowly impressed, punctures obscurely indicated; interstriae twice as wide as striae, punctures moderately large, numerous, confused, each with its anterior margins slightly elevated but not at all granulate. Declivity steep, convex; striae less strongly, more narrowly impressed than on disc; interstriae 1 and 3 rather strongly elevated, 1 bearing 11,3 bearing 13 moderately coarse, low teeth, $5,7,8$, and 9 each bearing 3 to 5 slightly smaller teeth, 2 narrower than 1 or 3 and punctured throughout. Vestiture consisting of fine and coarse interstrial hair on anterior half of disc, becoming scalelike toward declivity, scales abundant on declivity, each scale about three to five times as long as wide.

Female.- Similar to male except frons convex, carina longer, granules largely obsolete; discal interstriae armed by numerous, confused, small crenulations; declivital interstriae 1 and 3 less strongly elevated, teeth smaller, scales somewhat more abundant.

Distribution.- British Columbia and Washington to N Idaho.

CANADA: British Columbia: Pavillon Lake, 8-VII-72, Juniperus scopulorum, D. E. Bright. USA: Idaho: Harvard, Latah Co., 14-VIII-56, E. C. Clark. Washington: Fairfax, I4-V-34, Hopk. U.S. 18859-B, J. A. Beal, W. J. Buckhorn; Mt. Rainier N. P., 29-X-30, Hopk. U.S. I8924C, F. P. Keen, W. J. Buckhorn; all from the following named host.

Host.- Chamaecyparis nootkatensis and one series from Juniperus scopulorum.

Brology. - Reared from small branches of the host tree. Nothing more has been recorded.

Notes. - The above descriptions were based on the holotype and on 103 other specimens.

## 29. Phloeosinus hoferi Blackman Fig. 94

Phlocosinus hoferi Blackman, 1942, Proc. U.S. Nat. Mus. 92:412 (Holotype, male; Ute Pass, Colorado: U.S. Nat. Mus., 55397)
Diagnosis.- This species is allied to keeni Blackman, but it is easily distinguished by characters summarized in the above key.

Male.- Length $1.7-2.4 \mathrm{~mm}, 2.06$ times as long as wide; color dark brown to black, elytra a lighter brown.

Frons rather narrowly, rather deeply concave from epistoma to upper level of eyes, median carina reduced to an epistomal tubercle; surface shining, rather finely, closely punctured, a few small granules on dorsolateral margins of concavity; vestiture consisting of fine, moderately abundant, short hair.

Pronotum 0.86 times as long as wide; outline, sculpture, and pubescence as in keeni.

Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; outline as in keeni; basal margins each armed by 9 to 11 crenulations; striae rather shallowly impressed, punctures rather distinctly impressed; interstriae about twice as wide as striae, rather coarsely, closely punctured throughout, punctures confused, mostly with their anterior margins slightly elevated, a very few feebly granulate. Declivity steep, convex; striae slightly narrower than on disc; interstriae 1 and 3 moderately elevated, 1 and 3 each armed by nine coarse teeth, those near middle distinctly larger, 5 , 7 , and 9 each with about two smaller teeth, 2 narrower than 1 or 3 and rather coarsely punctured. Vestiture consisting of a mixture of fine and compressed setae of equal length on dise, becoming more nearly scalelike on declivity; each scale on declivity about two to three times as long as wide, some more slender setae also present.

Female.- Similar to male except frons convex, a very fine median carina on lower half; declivital elevation and teeth greatly reduced in height, scalelike setae stouter and much more abundant.

Distribution.-S British Columbia and North Dakota to Arizona and W Texas.

CANADA: British Columbia: Canyon House, Hat Creek, Kelowna, Marble Canyon, Williams Lake. USA: Arizona: Cave Creek Canyon in Chiricahua Mts., Lakeside, Oak Creek Canyon, Prescott N. F., Sedonia, Williams. California: Adin Summit in Modoc Co. Colorado: Blanca, Buena Vista, Boulder, Colorado N. F., Dolores, El Paso Co., Estes N. P., Ft. Collins, Ft. Garland, Garden of Gods, Golden, Poudre Canyon in Larimer Co., Ute Pass. Nevada: Baker, Caliente, Pioche. New Mexico: Capitan Mts., Capulin, Las Vegas, Meek, Ruidoso, Vermejo. North Dakota: Roosevelt N. P. in McKenzie Co. South Dakota: Black Hills. Texas: Davis Mits. Utah: Beaver, Brighton, Bryce Canyon N. P., Hatch, Kamas, Logan, Logan Canyon, Manila, Oak Creek Canyon in Millard Co., Panguitch. Wyoming: Cody, Ft. Bridger, Lusk. Yellowstone N. P.
Hosts.- Juniperus deppeana, J. osteosperna, and J. scopulorim.

Biology. - Small branches and twigs usually are selected for attack by this species. The tunnels appear similar to those described above for the genus.

Notes. - The above descriptions were based on the holotype and on 396 other specimens.
Characters correlated with geographic origin in this common species were not apparent.

## Genus ChrAMESL'S LeConte

Chramesus LeConte, 1865, Trans. Amer. Ent. Soc. 2:168 (Type-species: Chramesus hicoriae LeConte, monobasic).
Rhopalopleurus Chapuis. 1869, Synopsis des Scolytides, p. 46 (Type-species: Rhopalopleurus tuberculatus Chapuis, subsequent designation by Hopkins, 1914 Proc. U.S. Nat. Mus. 48:128); LeConte, 1876. Proc. Amer. Philos. Soc. 15:37. Synonymy Thaumasinulus Reitter, 1913. Weiner Ent. Zeit. 32(Beiheft):39 (Type-species: Dendrosinus bonnairei Reitter $=$ Chramesus rotundatus Chapuis; Eggers, 1940, Ent. Blätt. 36:61. Synonymy
Prochramesus Wood. 1956, Canadian Ent. 85:254 (Typespecies: Prochramesus annectans Wood, original designation): Schedl, 1963. Ent. Abh. Ber. Mus. Tierk. Dresden 28:258. Synonymy
Diagnosis.- This genus is distinguished from Pseudochramesus Blackman by the sexually dimorphic frons, by the 5 -segmented antennal funicle, by the large, flattened, very strongly asymmetrical antennal club, which is aseptate and entirely devoid of indications of sutures, and by other characters mentioned in the above key to genera.
Description.- Length $1.2-2.7 \mathrm{~mm}$, 1.4-2.3 times as long as wide. Male frons usually impressed or excavated, epistomal or lateral margins often armed, female flat to
convex, rarely armed, surface sculpture and vestiture simple. Eye entire; elongate. Antennal funicle 5 -segmented; club strongly flattened, large, strongly asymmetrical, devoid of all indications of segmentation. Pronotum smooth to coarsely reticulate with moderately fine to coarse punctures; anterior half commonly asperate, particularly in lateral areas. Scutellum small, round, visible in all except one species. Crenulations on elytral bases variable, usually well developed; striae clearly indicated, punctures variable; interstriae usually feebly convex. Vestiture variable, consisting of scales and/or hair.

Distribution.-S California and E Canada, to Argentina. Approximately 57 species are known; 36 of these occur in North and Central America.

Brology.- Except for the bigamous incomptus, the species are monogamous and mostly phloeophagous. The male constructs the entrance tunnel and turning niche; one
(rarely two) egg tunnel, longitudinal, oblique, or transverse, is constructed by the female in the cambium region or, less commonly, entirely in the wood. The larval tunnels radiate out from the niches along the egg gallery and most commonly turn gradually to parallel the grain of the wood; initially they are largely in the phloem (except xylophagous species), but later may engrave the wood or enter it entirely. They usually breed in small branches and almost never in material larger than 10 cm in diameter.

Notes.- Several very distinctive species groups occur within the genus; however, any division of the group into genera or subgenera appears unnecessary at this time.
Schedl (1940:337) reported rotundatus Chapuis from Mexico. Although several Mexican species superficially resemble rotundatus, I have yet to see an authentic specimen of Chapuis' species from Mexico. Schedl's specimens were not examined.

## Key to the Species of Chramesus

1. Slender, body 2.3 times as long as wide; male frons broad, transversely, concavely impressed below upper level of eyes, lateral margins not at all elevated or armed; male epistomal margin unarmed; scape not ornamented by a tuft of hair; scutellum not visible; setae on pronotum and elytra rather long, slender; declivital interstriae 2 strongly narrowed toward apex; Michoacán; Clematus; $1.9-2.1 \mathrm{~mm}$

- Male epistoma armed or else lateral margins of frons elevated and usually also armed (obscure in editus); scutellum snall but distinct; usually stouter; in other hosts
2(1). Male epistoma armed by a conspicuous, median tubercle, spine or carina; lateral margins of male frons subacute but not elevated or armed; antennal scape of male (and sometimes female) ornamented by a tuft of hair; vestiture of pronotum short, stout, almost scalelike, abundant; antennal club comparatively small, 1.6-2.1 times as long as wide; body rather slender, 1.7-2.0 times as long as wide
Male epistoma unarmed (except two tubercles in corniger), lateral margins elevated (except editus, cecropiae) and usually armed; male antennal scape not ornamented by hair (except ingens, wisteriae, chapuisii); at least part of pronotal vestiture hairlike; body stout, 1.5-1.7 times as long as wide (except slender in annectans, gracilis)
3a(2). Male epistoma subacutely elevated on median fourth, not forming a median tubercle or spine; interstriae about as wide as striae, interstrial tubercles on declivity moderately coarse; pronotal asperities more numerous, more widely dispersed; male scape without a tuft of long setae; Costa Rica to Venezuela; Bignoniaceae vine; $1.2-1.3 \mathrm{~mm}$
- Male epistoma armed by a conspicuous median tubercle or spine; interstriae about twice as wide as striae (except dentatus), interstrial tubercles much smaller, pronotal asperities sparse, confined to anterolateral areas; male scape (sometimes female also) ornamented by a conspicuous tuft of long setae
$3 \mathrm{~b}(3 \mathrm{a})$. Discal striae as wide as or slightly wider than interstriae; erect interstrial bristles in uniseriate rows, each almost as long as distance between rows, spaced within a row by much less than length of bristle; female epistoma unarmed, scape ornamented by very few hairlike setae; S Arizona to $S$ California; Quercus; $1.5-1.7 \mathrm{~mm}$
- Discal striae distinctly narrower than interstriae; erect interstrial scales within uniseriate rows about half as long as distance between rows, spaced within a row by one to several times length of erect scale; female epistoma armed or not, female scape ornamented or not
4(3). All pronotal and elytral setae light in color; female frons convex, epistoma unarmed; female scape not ornamented by a tuft of hair; striae coarser and deeper, almost as wide as interstriae; each scale in ground vestiture on pronotum and elytra as long as wide; Nayarit and Colima; 1.2-1.7 mm

3. unicornis Wood

- Pronotum and elytra with dark and light setae intermixed; female frons flattened or concave, epistoma armed by a median tubercle similar to but smaller than in male; female scape bearing a tuft of hair; striae narrower, punctures usually elongate, not as deep; ground vestiture of setae mostly much longer
than wide (except secus) ...........................................................
5(4). Larger; pronotal scales only slightly longer than wide, not longer or more slender in posteromedian area, those on anterior margin only slightly longer; erect elytral scales stout, mostly two or three times as long as wide, none more than four times as long as wide; declivital interstriae unarmed; Nayarit to Oaxaca; 1.7 mm
- Smaller; pronotal scales elongate, distinctly longer in posteromedian area, considerably longer on anterior margin; erect elytral scales almost all more than four times as long as wide
6(5). Declivital interstriae unarmed; female frons moderately concave on central half; dark scales predominate on pronotum and elytra; Hidalgo; Acacia; $1.3-1.5 \mathrm{~mm}$ granules; female frons weakly impressed, planoconcave; pale scales predominate on pronotum and elytra; Texas to Nuevo León and Tamaulipas; Mimosa etc.; $1.2-1.4 \mathrm{~mm}$
$7(2)$. Body slender, 2.3 or more times as long as wide; antennal club apically pointed, vestiture coarser, less abundant; male frons laterally armed by a pair of quadrate dentations distinctly displaced mesally from lateral margins (except unarmed in editus); in monocotyledonous hosts
- Body stout, less than 1.7 times as long as wide; antennal club with apex rounded, vestiture usually much finer, dense; lateral margins armed by one or more pairs of pointed dentations (except unarmed in cecropiae and corniger); in dicotyledonous hosts
8(7). Male frons with lateral margins obscurely elevated, unarmed; male scape ornamented by a tuft of long hair; interstriae as wide as striae; elytral ground vestiture short, confused, less than half as long as erect, blunt, flattened bristles; Durango, Oaxaca; $1.7-2.0 \mathrm{~mm}$
- Male frons with lateral margins more acutely elevated and armed by a pair of large subquadrate tubercles; interstriae twice as wide as striae; elytral vestiture three-ranked, shorter setae on margins, longer erect bristles form a median row
9(8). Pronotal punctures moderately coarse, rather shallow, each usually accompanied by a small granule; striae feebly impressed, punctures moderately coarse; interstrial setae in ground cover less abundant, indistinctly plumose; erect declivital interstrial bristles at least two-thirds as long as distance between rows; Oaxaca; Nolena; 1.9-2.4 mm

8. annectans (Wood)

- Pronotal punctures small to minute, often entirely replaced by accompanying granules; striae not at all impressed, punctures much less strongly impressed; interstrial setae in ground cover more abundant and much more strongly plumose; declivital bristles usually not more than half as long as distance between rows; Costa Rica to Panama; Bambusa; 2.2-2.7 mm

9. gracilis Wood

10(7). Male frons longitudinally sulcate (weakly concave in demissus), sulcus ending well below upper level of eyes, lateral margins unarmed; interstrial bristles slender, ground vestiture entirely absent (except sparse scales on posterior half in demissus)
Male frons concavely impressed, lateral margins armed by one or two pairs of tubercles (margins acute but unarmed in aquilus and signatipennis); interstrial ground vestiture abundant, usually extending to elytral base
11(10). Interstriae twice as wide as striae, crenulations and fine bristles confused on disc; pronotum glabrous except at margins, anterior margin in male armed by several low asperities; Costa Rica; 2.2-2.8 mm
10. ingens Wood

- Interstriae little if any wider than striae, tubercles and bristles uniseriate; pronotal disc setose
12(11). Larger; posterior half of elytra with sparse ground cover of small scales; interstriae rather broadly crenulate, particularly toward base; male frons impressed at and just above level of antennal insertion, surface reticulate; Guatemala; $2.0-2.3 \mathrm{~mm}$
Smaller; elytral ground vestiture absent; interstrial tubercles narrow to base
13(12). Male frontal sulcus reaching epistomal margin on median third, with a pair of submarginal epistomal tubercles, upper area of frons finely rugose-reticulate; bristles on discal interstriae 2 confused; Veracruz; 1.3-1.4 mm
- Male frons slightly elevated just above level of antennal insertion, elevated area transversely strigose; Celcropia leaf petioles; Costa Rica; $1.2-1.3 \mathrm{~mm}$

14(10). Male frontal excavation ending well below upper level of eyes, lateral margins armed at level of antennal insertions by two pairs of teeth of about equal size; posterior half of pronotal disc rather coarsely punctured, devoid of tubercles; pronotal vestiture of slender scales, each about six times as long as wide

- $\quad \begin{aligned} & \text { Male frontal excavation extending at least to upper level of eyes (except hi- } \\ & \text { coriae), lateral margins armed by not more than one pair of teeth; sculpture }\end{aligned}$ coriae), lateral margin
and vestiture variable
15(14). Larger; elytral ground vestiture longer, more slender, each scale two or more times as long as wide, erect bristles short, stouter; pronotal punctures usually coarse; Puebla; 2.0-2.2 mm
- Smaller; elytral ground vestiture very short, stout, each scale about as long as wide, erect bristles much more slender and longer, except in southern half of distribution; pronotal punctures usually smaller; Canavalia villosa; Nayarit to Panama; $1.4-2.0 \mathrm{~mm}$

16(15). Lateral margins of male frons acutely elevated but entirely unarmed; ground vestiture on basal half of elytral disc indistinguishable from erect bristles, confused, shorter posteriorly and erect bristles in rows; pronotum strongly reticulate; Chiapas; $1.5-1.8 \mathrm{~mm}$

- Lateral margins of male frons armed by a pair of denticles or strong serrations (except signatipennis); ground vestiture on elytra distinguishable from erect bristles to base

17(16). (?)Male epistomal margin acutely elevated, lateral margins of frons unarmed; pronotum strongly reticulate; interstrial ground vestiture short, slender, erect scales in rows, short, each about twice as long as wide, one-third as long as distance between rows, less than half as long as distance between scales within a row; Costa Rica; 1.4 mm

- Male epistoma not acutely elevated, lateral margins of frons armed by a pair of tubercles or strong serrations; vestiture not as above
18(17). Lateral margins of male frons very strongly, acutely elevated, ending abruptly dorsally at a level one-third distance from antennal insertion to upper level of eyes; striae weakly impressed, punctures minute, interstriae at least four times as wide as punctures; pronotal disc minutely punctured, devoid of tubercles; elytral ground vestiture of short scales each very slightly longer than wide, erect scales about half as long as distance between rows, each about four to five times as long as wide; Florida and Arizona to Honduras; Celtis, Condalia; $1.7-2.4 \mathrm{~mm}$

18. subopacus Schaeffer

- Lateral margins of male frons weakly to moderately elevated, armed at level of antennal insertion by a pointed tubercle; elytral and pronotal sculpture and vestiture variable

19(18). Elytral ground vestiture less abundant, oriented on each interstriae into one row on each side of erect bristles (obscure in some asperatus); each setae in elytral ground vestiture slender, three or more times as long as wide (except some asperatus); marginal crenulations on elytral bases near scutellum very coarse, isolated; proepimeral area transversely strigose (weak in hicoriae, asperatus)

20(19). Male frontal excavation scarcely attaining upper level of eyes; erect interstrial bristles each at least equal in length to distance between rows of bristles; proepimeral area feebly if at all strigose; E Texas and Wisconsin to Quebec and Georgia; Carya; 1.5-1.9 mm (see also 19b. atkinsoni Wood) as long as wide, erect bristles slender, their diameters usually not greater than setae in ground cover striae entirely without tubercles; pronotal crenulations coarser, more widely distributed; Arizona to Chihuahua; Rhamnus, Morus; 1.2-1.8 mm

23(21). Proepimeral area feebly strigose over a very limited area; erect interstrial bristles uniformly coarse, few if any laterally compressed; female frons strongly reticulate, punctures largely obsolete; Arizona, New Mexico; Robinia; 1.4-1.9 mm
22. asperatus Schaeffer

- Proepimeral area rather coarsely, transversely strigose over a rather large area; erect interstrial bristles strongly, laterally compressed on disc, more commonly slender, almost hairlike and often shorter on declivity; female frons very feebly reticulate, with rather abundant, shallow, somewhat obscure punctures over entire surface; Puebla; $1.4-1.8 \mathrm{~mm}$

23. strigatus Wood

24(19). Strial punctures very coarse, deep, their diameters about equal to width of an interstriae; interstriae crenulate, tubercles very coarse, each bearing on its posterior slope a coarse bristle, each bristle about equal in length to distance between rows of bristles; male declivital interstriae 2 devoid of tubercles and bristles; male antennal scape bearing a conspicuous tuft of long hair; Guatemala; $1.5-2.1 \mathrm{~mm}$
24. punctatus Wood

- Diameters of strial punctures considerably less than half as great as width of an interstriae; erect interstrial bristles much shorter than distance separating rows of bristles
25(24). Erect interstrial bristles slender, almost hairlike; striae rather strongly impressed, interstrial tubercles coarse, about equally developed in both sexes, pronotal vestiture hairlike; male frons shallowly concave, concavity not attaining upper level of eyes; Panama; Inga; 2.4-2.7 mm

25. vastus Wood

- Erect interstrial bristles scalelike; with a different combination of other characters
26(25). Pronotal scales slender or bristlelike, each at least six times as long as wide (those near base sometimes stout); male interstriae unarmed by tubercles (except xylophagus and wisteriae)

Pronotal scales rather broad, each less than four times as long as wide; male

- $\quad \begin{aligned} & \text { Pronotal scales rather } \\ & \text { interstriae armed or not }\end{aligned}$ ..... 34

27(26). Erect interstrial bristles short, about twice as long as ground setae, spaced within a row by three to four or more times length of a bristle; male strial punctures obsolete or at most feebly indicated toward base; Nayarit; Inga; $1.2-1.5 \mathrm{~mm}$within a row by less than two and one-half times length of a bristle28

28(27). Male scape bearing a tuft of long, yellow hair; antennal club smaller, rather stout, not more than 2.2 times as long as wide

- $\quad$ Scape not ornamented by hair in either sex (a few hairs in male microporosus); antennal club larger and more slender, at least 2.4 times as long as wide30
$29(28)$. Tuft of hair on male scape smaller, male frons less strongly impressed, particularly on upper half; male interstriae armed by granules about as large as those of female; Mississippi; Wisteria; $1.6-1.8 \mathrm{~mm}$

27. wisteriae Wood Tuft of hair on male scape larger, male frons more strongly impressed, particularly on upper half; male interstriae entirely devoid of rows of granules; Kansas and Pennsylvania to San Luis Potosí and Florida; Celtis; 1.5-2.0 mm
28. chapuisi LeConte

- Size smaller; usually fewer than 6 pairs of submarginal....................................................................................................... bases ..............................................
31(30). Male scape setose, strial punctures 33 der, interstrial bristles each six to obsolete or nearly so, vestiture rather slender, interstrial bristles each six to eight or more times as long as wide; female strial punctures very small, interstrial granules smaller; Chiapas; $1.8-2.4 \mathrm{~mm} .$. Male scape without long setae, strial punctures normal, int.....................................................porosus Wood about four times as long as wide long setae near its upper margin, lateral denticles small, pointed, located at lower level of antemnal insertion; strial punctures slightly larger, vestiture unicolorous; Veracruz; 2.2-2.5 mm .................................................. 29. periosus Wood
- Male frons more strongly impressed on upper third, setae obscure, very short, lateral denticles rather large, subquadrate, located at or slightly above upper level of antennal insertion; strial punctures smaller, vestiture of mixed lightand dark-colored setae; Veracruz; $1.8-2.3 \mathrm{~mm}$

30. variabilis Wood

33(30). Male discal interstriae each with a row of fine granules; pronotal setae slender, essentially of one kind; scales on elytral disc much smaller, each about onefifth as wide as an interstriae or less; Nayarit, Sinaloa; Inga; 1.6-1.9 mm 32. xylophagus Wood slender; scales on elytral disc rather large, at least one-fourth as wide as interstriae; Veracruz to Yucatán; $1.3-1.6 \mathrm{~mm}$
34(26). Dark- and light-colored scales on pronotum and elytra forming a conspicuous color pattern; erect interstrial scales longer and more slender, at least twothirds as long as distance between rows, each scale at least four times as long as wide; Honduras; Cestrum scandens; $1.4-1.7 \mathrm{~mm}$.............................34. bicolor Wood Pronotal and elytral scales uniformly pale in color; erect interstrial scales short,
stout, not longer than half distance between

35(34). Erect interstrial scales little if any longer than ground scales; pronotal scales small, each very slightly longer than wide in discal area; Honduras; 1.2-1.3 mm 35. minulus Wood

- Erect interstrial scales about twice as long as ground scal....................................................... minulus slender, more than three times as long as wide
36(35). Body stouter, 1.6 times as long as wide; declivital interstriae 1-3 of equal height and sculpture; male frons less strongly concave, denticles on lateral margins; Costa Rica to Venezuela; Acacia; 1.5-1.8 mm ........... 36. acacicolens Wood
- Body more slender, 1.9 times as long as wide; declivital interstriae 1 and 3 very slightly higher than 2 and with larger granules, 2 usually narrower; male frons much more deeply concave, with denticles displaced mesad slightly from lateral margins; Chiapas; Acacia; 1.4-1.7 mm

37. disparilis Wood

## 1. Chramesus incomptus Wood

Chramesus ineomptus Wood, 1967, Great Basin Nat. 27:90 (Holotype, male; Morelia, Michoacán, Mexico: Wood Coll.)
Diagnosis.- A slender species with unique sculpture of the pronotum, fine vestiture, and sculpture of the male frons not found elsewhere in the genus. It might be confused with editus (Bright).

Male.- Length $1.9-2.1 \mathrm{~mm}, 2.3$ times as long as wide; body color brown.

Frons strongly, transversely impressed just below middle, upper area flattened to vertex, lower area strongly raised to epistoma; lateral areas rounded, unarmed; epistomal lobe conspicuous, with a pair of small tubercles at its base; surface reticulate, with small, deep punctures at sides and above; vestiture fine, short, somewhat more abundant at sides and above, rather inconspicuous. Antennal club rather small, apically pointed, 1.6 times as long as wide.

Pronotum 0.9 times as long as wide; widest about one-third pronotum length from base, sides moderately arcuate, distinctly constricted just behind anterior margin; surface minutely granulate and with small, moderately close, shining, rounded granules on anterior or lateral margins of fine, obscure punctures; vestiture consisting of rather long, moderately abundant stout hair.

Elytra 1.35 times as long as wide, 1.7 times as long as pronotum; sides almost straight on basal two-thirds, very slightly wider posteriorly, broadly rounded behind; scutellum depressed, not present in usual sense; basal margins each armed by 13 small crenulations; striae rather weakly impressed, punctures rather large, deep; interstriae slightly wider than striae, weakly convex, surface irregular, punctures rather numerous, confused, most granulate or subgranulate on anterior side; interstriae 2 subcrenulate to well behind base. Declivity rather steep, broadly convex; only striae 1 weakly impressed, punctures somewhat reduced in size; interstriae almost smooth, 3 and upper third of 1 and 2 with sparse, uniseriate, rounded granules. Vestiture moderately long, consisting of coarse, delicate, hairlike setae, toward declivity median interstrial rows becoming distinctly longer than similar, shorter, ground vestiture.

Female.- Similar to male except frons irregularly convex with an indefinite, subfoveate, median impression, surface reti-culate-granulate; epistomal tubercles present; elytral declivity more narrowly convex, interstrial tubercles on 2 and especially 1 extending to middle or below.

Distribution.- Michoacán.
MEXICO: Michoacán: 33 km W Morelia, 16-V1-65, 2200 m , Clematis, S. L. Wood.

Brology.- The biramous, diagonal parent tunnels were made in dying stems larger than 1 cm in diameter. This species is unique within the genus in that two females were usually associated with each male.

Notes.- The above treatment was based on the type series of 17 specimens.

## 2a. Chramesus denticulatus Wood

Chramesus dentieulatus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):6 (20 km SW El Vigía, Merida, Venezuela; Wood Coll.)
Diagnosis.- This unique species is distinguished from other known species by the small size, by the unarmed male frons, by the finely asperate anterolateral areas of the pronotum, and by the finely dentate declivital interstriae.

Male.-Length 1.2-1.3 mm, 1.9 times as long as wide; color yellowish brown.

Frons rather deeply concave on a subcircular area from epistoma to upper level of eyes, lateral margins subacute, unarmed; epistomal margin carinately elevated, more strongly on median third; surface reticulate, punctures minute, obscure; vestiture uniformly short, of coarse, uniformly distributed setae.

Pronotum 0.77 times as long as wide; widest near base, sides convergently arcuate to broadly rounded anterior margin; surface reticulate, almost uniformly covered by isolated, rather widely spaced, small subasperate tubercles. Vestiture short, of almost equal numbers of very fine hair and rather broad scales.

Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, broadly rounded behind, posterior outline interrupted by declivital teeth; striae moderately impressed, punctures rather coarse, shallow; interstriae subreticulate, weakly
convex, as wide as striae, punctures replaced by rows of granules, very fine at base, becoming coarse toward declivity. Declivity rather steep, broadly convex; striae narrower and deeper than on disc; interstriae more narrowly convex, each armed by a row of close, rather small pointed teeth, except almost obsolete on lower half of 2 . Vestiture of ground cover formed by two indefinite rows of short, stout setae on margins of each interstriae, and a central row of short, erect scales; each scale about twice as long as wide, spaced within and between rows by slightly more than twice length of a scale; scales about twice as long as ground setae.

Female.-Similar to male except frons weakly concave, epistoma weakly elevated, frontal vestiture of short scales; pronotal asperities larger in anterolateral areas; interstrial teeth on declivity slightly smaller, regularly present on 2.

Distribution.- Costa Rica to Venezuela.
costa rica: La Selva near Puerto Viejo. Heredia, 18-II-80, $50 \mathrm{~m}, \mathrm{H}$. and A. Howden (Canadian Nat. Coll.). venezuela: 20 km SW El Vigía, Merida, 21-Xl-69, Bignoniaceae vine (liana), S. L. Wood.
Notes. - The above treatment was based on the type series of five specimens and on two other specimens.

## 2b. Chramesus dentatus Schaeffer

Fig. 97
Chramesus dentatus Schaeffer, 1908, J. New York Ent. Soc. 16:221 (Lectotype, female; Huachuca Mts., Arizona; U.S. Nat. Mus., 42487 , subsequent designation by Blackman, 1938, J. Washington Acad. Sci. 28:544)
Chramesus barbatus Eggers, 1931, Ent. Blätt. 26:169 (Holotype, male; Valle de Mexico; Berlin Zool. Mus.); Wood, 1972, Great Basin Nat. 32:192. Synonymy
Diagnosis.- In this and the four following species the male epistoma is armed by a large, median tubercle. This species differs from the other four by the coarser discal striae, by the much longer interstrial bristles, and by the tufted male scape.
Male.- Length $1.5-1.7 \mathrm{~mm}, 1.9$ times as long as wide; color dark brown.
Frons broadly, rather deeply concave from epistomal margin to vertex, lateral margins subacute, unarmed; epistomal margin armed by a conspicuous, median, pointed tubercle; surface rugose-reticulate, minute punctures
obscure; vestiture moderately short, sparse, rather uniformly distributed. Scape elongate, bearing a tuft of yellow hair; club 1.9 times as long as wide.

Pronotum 0.81 times as long as wide; widest at base, sides arcuately converging to rather broadly rounded anterior margin; surface finely granulate-punctate, subasperate in anterolateral areas; vestiture of very stout, short, subscalelike bristles of two sizes.

Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; scutellum small, depressed; basal margins each armed by 13 crenulations, several submarginal crenulations on interstriae 2 to 4 ; striae weakly impressed, punctures coarse, deep interstriae as wide as striae, feebly convex, almost smooth, punctures small, close, confused, a median row very feebly granulate. Declivity steep, convex; striae and interstriae slightly narrower, otherwise as on disc. Vestiture of ground cover of small, suberect scales, each slightly longer than wide; and interstrial rows of erect bristles, each about four times as long as ground scales and almost equal in length to distance between rows, separated within a row by slightly shorter distances.

Female.-Similar to male except frons very shallowly concave, epistomal tubercle smaller; pronotal and elytral granules slightly larger.

Distribution.-S Arizona and $S$ California.

USA: Arizona: Huachuca Mts., No. 186. California: Warner's, San Diego Co., VII-19, E. C. Van Dyke.

Host.-Quercus sp.
Biology.- Collected from oak twigs girdled by Oncideres quercus Skinner.
Notes. - The above treatment was based on the lectotype and on 13 other specimens.

## 3. Chramesus unicornis Wood

Chramesus unicornis Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2): 4 (Holotype, male; Laguna Santa María, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from varius Wood by the less extensive male frontal impression, by the smaller tuft of setae on the scape, by the subquadrate pronotum, by the more strongly impressed striae

Fig. 97. Chramesus spp., antennae: 1 , subopacus, male; 2, asperatus, female; 3, hickoriae, female; 4, subopacus, female; 5. mimosae, male, 6, same, female; 7, dentatus, female, 8, same, male; 9, chapuisii, male. (After Blackman 1938:540.)
and strial punctures, and by the uniformly pale vestiture.

Male.- Length $1.3-1.6 \mathrm{~mm}, 2.0$ times as long as wide; color medium to light brown.

Frons deeply excavated from eye to eye from upper level of eyes to epistoma; lateral margins acute from just above level of antennal insertion to epistomal margin; surface rather coarsely reticulate above, becoming obscurely reticulate and shining below, armed by a large, pointed, median tubercle immediately above epistomal margin; vestiture sparse, inconspicuous. Antennal scape bearing a small tuft of fewer than a dozen long, yellow setae; club small for this genus, 1.9 times as long as wide.

Pronotum 0.83 times as long as wide; widest at base, sides feebly arcuate and converging slightly on more than basal twothirds, then rather abruptly constricted just before broadly rounded anterior margin; surface rather coarsely reticulate, punctures very close, rather shallow, irregular in outline, anterolateral asperities obscure. Vestiture consisting of short, rather abundant, stout, almost scalelike setae.
Elytra 1.2 times as long as wide, 1.5 times as long as pronotum; sides straight and subparallel on basal two-thirds to declivital base, then rather broadly rounded behind; basal margins armed by 14 crenulations; striae slightly impressed, large punctures deeply impressed; interstriae as wide as striae, convex, each bearing a row of fine, pointed tubercles. Declivity moderately steep, convex, essentially as on disc except area at junction of interstriae 3 and 9 slightly elevated. Vestiture consisting of moderately abundant, small broad scales, and rows of erect interstrial scales, each scale about three times as long as ground cover, each half as long as distance between rows and almost equal in length to distance between erect scales within a row, each about four times as long as wide; not longer on declivity.
Female.- Similar to male except frons convex, coarsely reticulate to epistoma, median tubercle absent and pronotal asperities slightly larger.
Distribution.- Colima and Nayarit.
MEXICO: Colima: 25 km W Armeria, $30-\mathrm{VI}-65,20 \mathrm{~m}$, No. I43. Nayarit: Laguna Santa María, 6-VII-65, 1000 m, No. 201, S. L. Wood.

Biology.- The larval and adult mines were in the cambium of a large woody vine (liana), in which the larger stems were square in cross section.

Notes.- The above treatment was based on the type series of 82 specimens.

## 4. Chramesus secus Wood

Chramesus secus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):4 (Holotype, male; Laguna Santa María, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is very closely related to varius Wood, but differs by the larger size, by the uniformly pale color of the vestiture, by the more finely sculptured pronotum, and by the shorter, more scalelike vestiture.

Male.- Length $1.7 \mathrm{~mm}, 1.7$ times as long as wide; color brown with white vestiture on pronotum and interstriae 1 , tan elsewhere.

Exactly as in varius except as noted above and also setae on all margins of pronotum shorter and stouter; median extension of basal margin of pronotum less pronounced; elytral vestiture appearing more abundant and each seta conspicuously wider.

Distribution. - Nayarit and Oaxaca.
Mexico: Nayarit: Laguna Santa María, 6-VII-65, 1000 m, No. 201, S. L. Wood. Oaxaca: 6 km N Totolapan, 20-VI-67, 1100 m , No. 66, Acacia sp.. S. L. Wood.
Biology. - The holotype was taken with a long series of unicornis Wood from a large woody vine (liana) having the larger stems square in cross section.
Notes. - The above treatment was based on the unique holotype. The Oaxaca series apparently represents this species, but the host was thought to be Acacia.

## 5. Chramesus varius Wood

Chramesus varius Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):4 (Holotype, male; Ixmiquilpan, Hidalgo, Mexico; Wood Coll.)
Diagnosis.- A species rather closely related to mimosae Blackman, but distinguished by the absence of interstrial granules, by the predominance of dark scales, and by the moderately concave female frons.

Male.- Length 1.3-1.5 mm, 1.7 times as long as wide; color brown with light scales on basal fourth and lateral margins of pronotum and on interstriae 1 and lateral areas of elytral disc, dark scales predominant elsewhere.

Frons deeply, broadly concave from eye to eye from well above eyes to epistoma; excavated area reticulate-granulate; lateral margin acute only at level of antennal bases, unarmed; epistomal margin bearing a large, pointed median tubercle; vestiture consisting of moderately abundant, stout setae. Scape bearing small tuft of long, yellow, subplumose setae; club rather small for this genus, its apex not pointed, 2.1 times as long as wide.
Pronotum 0.82 times as long as wide; widest on basal third, sides strongly, convergently arcuate toward broadly rounded anterior margin; anterolateral areas with a few fine asperities; surface coarsely reticulate, punctures rather fine, shallow, moderately close, many of them subvulcanate on posterior area; basal margin bisinuate; vestiture stout, short, essentially scalelike.

Elytra 1.14 times as long as wide, 1.6 times as long as pronotum; bases each armed by 11 marginal crenulations on interstriae 2 to 9 ; scutellum depressed, not visible in usual sense; striae weakly impressed, stronger toward declivity, punctures small, impressed; interstriae twice as wide as striae, convex, surface evidently superficially reticulate, punctures very fine, usually obscured by setae. Declivity convex, steep; striae slightly deeper, interstriae slightly narrower than on disc. Vestiture consisting of moderately abundant, stout, almost scalelike, erect setae, and rows of erect scales each about twice as long as ground vestiture and about four or five times as long as wide.

Female.- Similar to male except frons more narrowly, shallowly concave, with median tubercle very slightly smaller; pronotal crenulations larger and more numerous.

Distribution.- Hidalgo.
MEXICO: Hidalgo: 25 km N 1xmiquilpan, 10-VII-67, $1900 \mathrm{~m}, \mathrm{No}$. I88. Acacia S. L. Wood.

Biology. - The newly formed parental galleries were in a broken branch about 4 cm in diameter.

Notes.- The above treatment was based on the type series of 14 specimens.

6. Chramesus mimosae Blackman<br>Fig. 97

Chramesus mimosae Blackman, 1938, J. Washington Acad. Sci. $28: 544$ (Holotype, female; Brownsville, Texas; U.S. Nat. Mus., 57803)
Diagnosis.- This species is distinguished from the closely related varius Wood by the presence of interstrial rows of small, rounded granules, by the predominance of pale scales on pronotum and elytra, and by the much less strongly concave female frons.

Male.- Length 1.3-1.6 mm, 1.7 times as long as wide; color dark brown with pale scales predominating, dark scales usually on anteromedian area of pronotum and on declivity, extending anteriorly on interstriae 2 to 4 to base (variable).

Frons as in varius except slightly less strongly concave; antenna as in varius.

Pronotum as in varius except surface smoother, punctures finer, deeper, discal granules finer; vestiture shorter, stouter, pale in color.

Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; basal crenulations and outline as in varius; striae feebly impressed, punctures oval, moderately coarse, deep; interstriae less than twice as wide as striae, surface smooth, fine punctures confused, median row finely granulate. Declivity convex, rather steep; striae moderately impressed, almost as wide as interstriae. Vestiture essentially as in varius except erect bristles very slightly longer and more slender, each about five to six times as long as wide.

Female.- Similar to male except frons shallowly concave (much less strongly concave than female varius), epistomal tubercle slightly smaller.

Distribution.-S Texas to Tamaulipas and Nuevo León.
USA: Texas: Brownsville, 21-V-04, Mimosa lindheimeri, H. S. Barber; Southmost, 27 -1II-51, Mimosa, S. L. Wood. MEXICO: Tamaulipas: Las Norias near San Fernando, 14-VI-53, Mimosa, S. L. Wood. Nuevo León: Monterrey, XI-25, E. A. Schwarz.

Host. - Mimosa sp., Cassia lindheimeriana, Leucaena pulverulenta.

Biology. - Specimens were collected from broken branches less than 4 cm in diameter.

The gallery systems were in the cambium region.

Notes. - The above treatment was based on the holotype and on 623 other specimens.

## 7. Chramesus editus (Bright)

Prochramesus editus Bright, 1972, Canadian Ent. 104:1495 (Holotype, female; 20.5 km N Oaxaca, Oaxaca, Mexico; Canadian Nat. Coll., 12610)
Diagnosis.- This species is distinguished from incomptus Wood by the much more weakly rugose-reticulate pronotal surface, by the much shorter, stout pronotal setae, by the shorter, stouter, strongly plumose elytral setae in the ground cover, and by the absence of submarginal crenulations on the elytral bases.
Male.- Length $1.7-2.0 \mathrm{~mm}, 2.3$ times as long as wide; color very dark brown, elytra slightly lighter.

Frons very similar to incomptus except moderately concave from level of antennal insertion to slightly above upper level of eyes; lateral margins subacutely, feebly elevated from epistomal margin to level of antennal insertion; median half of lower third reticulate, glabrous. Antennal scape ornamented by about two dozen long setae; club rather small for this genus.

Pronotum 0.84 times as long as wide; surface rather rugose-reticulate, setiferous punctures very small, rather close, each with a small, rounded granule. Vestiture of short, stout setae, each about six times as long as wide.

Elytra 1.5 times as long as wide, 1.9 times as long as pronotum; outline as in incomptus; striae feebly impressed, punctures coarse, deep; interstriae as wide as striae, subshining, almost smooth, each with a row of rounded granules from base (without submarginal crenulations at base), punctures fine, obscure, confused. Declivity steep, convex; sculpture similar to disc except strial punctures slightly smaller. Vestiture of short, stout, plumose setae covering less than half of surface, and uniseriate rows of erect bristles, each bristle two to three times as long as ground cover, about eight times as long as wide, spaced between rows and within a row of about one and one-half times length of a bristle.

Female. - Similar to male except frons convex, reticulate, with a median fovea; antennal scape with setae normal.

Distribution.- Durango to Oaxaca.
MEXICO: Durango: $14 \mathrm{~km}(9$ miles) E El Palmito, Durango, $2500 \mathrm{~m}, 15-\mathrm{VI}-71$, shrub, D. E. Bright. Oaxaca: 20.5 km N Oaxaca 31-V-71, 2500 m . leguminous shrub, D. E. Bright.

Notes.- The above treatment was based on the holotype and on several paratypes.

## 8. Chramesus annectans (Wood) <br> Fig. 98

Prochramesus annectans Wood, 1956, Canadian Ent. 88:254 Holotype, female: Nochixtlan, Oaxaca: Snow Ent. Coll., Univ. Kansas)
Diagnosis.- This species is distinguished from the very closely related gracilis Wood by the characters summarized in the above key.

Male.- Length 1.9-2.4 mm, 2.3 times as long as wide; color black.

Frons rather deeply concave from epistoma to upper level of eyes; lateral margins rounded, armed just mesad of margin just above level of antennal insertion by a pair of subquadrate, rather large, blunt tubercles; surface reticulate, with sparse, minute, obscure punctures; vestiture fine, short, sparse. Antennal club apically pointed, 2.1 times as long as wide.

Pronotum 0.85 times as long as wide; widest at base, basal two-thirds weakly arcuate, feeble, converging anteriorly, then moderately constricted just behind rather broadly rounded anterior margin; surface subreticulate, rather coarsely, deeply, closely punctured on disc, punctures partly or largely replaced by rounded granules in lateral areas; vestiture short, rather abundant, consisting of fine and moderately stout bristles intermixed.

Elytra 1.5 times as long as wide, 2.0 times as long as pronotum; sides almost straight and parallel on very slightly less than basal threefourths, broadly rounded behind; scutellum small, round; basal margins each armed by 16 small crenulations; striae rather weakly innpressed, punctures moderately large, deep; interstriae as wide as striae, weakly convex, almost smooth, with uniseriate rows of subcrenulate, setiferous granules, each granule about half as wide as an interstriae. Declivity
convex, steep; strial punctures and interstrial granules smaller than on disc. Vestiture consisting of short, rather stout, rather abundant ground cover, and interstrial rows of erect, longer, slender bristles; each bristle about two-thirds as long as distance between rows.

Female.-Similar to male except frons flattened or feebly convex, tubercles smaller; pronotal granules extend to disc, punctures somewhat reduced.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 11 km SE Nochixtlán, 5-Vil-53, Nolena, S. L. Wood; 25 km SE Nochixtlán, 17-V1-67, No. 52, Nolena, S. L. Wood; 16 km S Oaxaca, 6-V1l-53. Nolena, S. L. Wood.

Host.- Nolena spp.
Brology.- This monogamous species attacks the dying fruiting stalks of its host. The transverse parental tunnels are in the woody tissue near the periphery. The larval mines follow the grain of the fibers.

Notes. - The above treatment was based on 24 paratypes and 36 topotypes.

## 9. Chramesus gracilis Wood

Chramesus gracilis Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 2$ (Holotype, male; San José, San José, Costa Rica: Wood Coll.)
Diagnosis.- This species is distinguished from the very closely related annectans (Wood) by the larger average size, by the much more finely, shallowly punctured pronotum, by the smaller, shallow, strial punctures, and by other characters indicated in the above key.

Male.- Length 2.2-2.7 mm, 2.25 times as long as wide; color dark brown to black, with white vestiture.

Frons rather deeply, concavely impressed from upper level of eyes to epistoma, lateral margins rounded, bearing mesad of margin just above level of antennal insertion a pair of large, squared processes as in annectans; surface coarsely reticulate, with a few fine, obscure punctures; vestiture fine, long, rather sparse. Antennal club acutely pointed, 2.6 times as long as wide.

Pronotum 0.9 times as long as wide; widest at base, sides weakly arcuate and converging slightly on basal two-thirds then rather strongly constricted before broadly rounded anterior margin; surface strongly reticulate, with fine, rather widely separated punctures, punctures subasperate in lateral areas;
vestiture consisting of stout semirecumbent bristles.

Elytra 1.5 times as long as wide, 1.9 times as long as pronotum; basal margins each armed by 15 small crenulations; sides straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures small, round, shallow, distinct; interstriae about three times as wide as striae, almost flat, smooth and shining with rather abundant, minute, setiferous, confused punctures and median rows of fine setiferous granules. Declivity steep, convex; striae weakly impressed; interstriae feebly convex. Vestiture consisting of rather abundant, short, subplumose scales and interstrial rows of somewhat longer erect bristles, each bristle about two-thirds as long as distance between rows.

Female.-Similar to male except frons very shallowly impressed, tubercles somewhat smaller; pronotal tubercles distinctly larger.

## Distribution.- Costa Rica to Panama.

COSTA RICA: University of Costa Rica Campus, San José, 12-IX-63, 1300 m , Japanese bamboo, S. L. Wood. Panama: Cerro Punta, Chiriqui, 19-23-V-77, H. and A. Howden.

Ноsт.- Bambusa vulgaris.
Biology.- This monogamous species was taken from dying stumps 10 cm or more in diameter. The diagonal, biramous, egg galleries were immediately below the surface of the wood. Larval mines were parallel to the grain of the wood.

Notes.- The above treatment was based on the type series of 85 specimens.

## 10. Chramesus ingens Wood

Chramesus ingens Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):3 (Holotype, male; Tapantí, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- This species is unique in having the antennal bases closer together and displaced more dorsad than usual; in having the elytral vestiture fine and of uniform length; and in having the male frons not exacavated, but the lateral margins elevated with their summits at a point well above the level of antennal insertion and not armed by pointed tubercles.

Male. - Length 2.2-2.8 mm, 1.6 times as long as wide; color dark brown to black.

Frons shallowly impressed from upper level of eyes to epistoma, with an indistinct elevation between antennal bases; lateral margins elevated on middle third, with a rounded summit just above antennal base; surface reticulate, with very fine punctures at sides and above; antennal bases closer together than eyes; distance from epistomal margin (omitting lobe) to antennal bases 1.6 times greatest width of an eye; frons subglabrous. Antennal scape with small tuft of hair; club 2.7 times as long as wide.
Pronotum 0.8 times as long as wide; base strongly bisinuate, basal angles broadly rounded, sides strongly arcuate, widest just behind middle, moderately constricted just behind broadly rounded anterior margin; entire surface reticulate, with small, sparse, finely subasperate punctures, much finer or absent in posteromedian area. Glabrous.

Elytra 1.03 times as long as wide, 1.5 times as long as pronotum; scutellum about twice as wide as long; basal margins each armed by about a dozen basally contiguous crenulations; sides straight and parallel on basal half, broadly rounded behind; striae narrowly impressed, punctures small, distinctly impressed; interstriae about three times as wide as striae, slightly convex, almost smooth with rather numerous, confused, small, rounded, setiferous granules. Declivity convex, moderately steep; about as on disc. Vestiture consisting of fine, erect, confused, hairlike setae, all of equal length, each shorter than a distance equal to width of an interstriae (about two-thirds as long).

Female.- Similar to male except lateral margin of frons very feebly elevated; pronotal punctures almost entirely devoid of small asperities.

Distribution.- Costa Rica.
COSTA RICA: Tapanti, Cartago, 24-X-63, $1300 \mathrm{~m}, \mathrm{~S}$. L. Wood; Puerto Viejo, Heredia, 12-III-64, 70 m , No. 486. S. L. Wood; Guapiles, Limón, 22-VIII-66, 100 m , No. I05, S. L. Wood.

Host.-Seriania mexicana? (probable error in identification).

Biology.- This monogamous species attacked a freshly cut vine 2 cm in diameter, and completed its development in less than 20 days. The egg galleries tended to be diagonal and in the cambium, but in the smaller parts of the stem they cut almost to the central axis. The host was identified by a plant
taxonomist as Serjania mexicana, but the texture of the soft, nonwoody tissues that turned black with age suggests an error in identification.

Notes. - The above treatment was based on the type series of 272 specimens and on 12 other specimens.

## 11. Chramesus corniger Wood

Chramesus corniger Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):8 (Holotype, male: Lago Catemaco, Veracruz, Mexico; Canadian Nat.
Coll.)
Diagnosis.- This species is unique in the genus. The male frons is very weakly impressed, the lateral margins are not elevated at all, and the lower frons in the male bears a pair of large denticles near but not on the epistomal margin. The elytral ground vestiture is absent.

Male.- Length 1.3-1.4 mm, 1.7 times as long as wide; color very dark brown, almost black, vestiture pale.

Frons very shallowly concave from epistoma almost to upper level of eyes, lateral margins rounded, not elevated; a pair of rather large tubercles just above epistomal margin, their bases separated by about onethird width of frons; surface subshining, finely rugulose, a few small, indistinct granules on upper half; vestiture of sparse, fine, inconspicuous hair. Antennal club moderately
large. large.

Pronotum 0.80 times as long as wide; widest near base, sides arcuately converging to rather weak constriction just before rather narrowly rounded anterior margin; entire surface strongly reticulate; punctures small, widely spaced, those on anterior half granulate to very finely asperate. Vestiture of short, stout bristles of moderate abundance.

Elytra 1.1 times as long as wide; sides almost straight and parallel on slightly more than basal half, broadly rounded behind; basal margins of elytra each armed by about 15 crenulations, one submarginal crenulation on interstriae 2 ; striae feebly impressed, punctures moderately coarse, close; interstriae slightly wider than striae, uniseriately, finely granulate except slightly confused on 2 , punctures not evident. Declivity rather steep, convex; sculpture about as on disc. Vestiture of interstrial rows of stout bristles, each 8-10
times as long as wide, slightly shorter than distance between rows, slightly confused on discal interstriae 2.

Female.-Similar to male except frons weakly convex, unarmed; pronotal granules smaller in median area, two or three of those on anterolateral angles crenulate.

Distribution.- Veracruz.
MEXICO: Veracruz: Lago Catemaco. 16-20-VI-69, D. E. Bright.

Notes.- The above treatment was based on the type series of eight specimens.

## 12. Chramesus cecropiae Wood

Chramesus cecropiae Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):5 (Holotype, male; Rincón de Osa, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- This is a unique species having the male frons not exacavated, more nearly protuberant at a level just above antennal insertion, and with the elytral ground vestiture absent; a row of stout bristles marks each interstriae.

Male.- Length 1.2-1.3 mm, 1.7 times as long as wide; color rather dark brown, elytra somewhat lighter.

Frons longitudinally flattened on two planes, transversely, weakly convex on upper third, then ascending rather abruptly to an indefinite, strongly arcuate line between antennal bases, its median point well above (dorsad) its lateral extremities; lower twothirds almost flat, lateral margins below very slightly elevated; surface above coarsely reticulate, lower area transversely strigose; vestiture consisting of a few hairlike setae on lateral areas on lower half. Antennal club moderately large for this genus, 2.3 times as long as wide.

Pronotum 0.82 times as long as wide; widest on basal third, sides arcuately converging to a slight constriction just before rather broadly rounded anterior margin; surface shining, subreticulate, with scattered, rather abundant tubercles of variable size on anterior three-fourths, some of those on anterolateral areas finely asperate; a few large, obscure punctures evident toward base. Vestiture rather sparse, consisting of a few stout setae over entire surface.

Elytra 1.1 times as long as wide, 1.4 times as long as pronotum; elytral bases armed by
about 12 crenulations; striae feebly if at all impressed, punctures large, moderately deep, distinct; interstriae very slightly wider than striae, very slightly irregular, brightly shining, each bearing a row of small, pointed, setiferous tubercles. Declivity rather steep, convex, sculptured essentially as on disc. Vestiture consisting of rows of interstrial bristles, each bristle somewhat flattened toward its apex and equal in length to distance between bristles within a row and three-fourths distance between rows; very minute strial hair also evident.

Female.- Similar to male except frons more evenly convex, coarsely reticulate throughout, with a median fovea on upper half; pronotal asperities larger, tubercles largely absent but replaced by shallow, rather obscure punctures.

Distribution.- Costa Rica.
costa RICA: 4 km SW Rincón de Osa, Puntarenas, 21, 28-1I-67, Cecropia petioles, D. D. Sliwa.

Notes.- The above treatment was based on the type series of four specimens.

## 13. Chramesus demissus Wood

Chramesus demissus Wood, 1967, Great Basin Nat. 27:93 (Holotype, male; Volcán Pacaya, Esquintla, Guatemala; Wood Coll.)
Diagnosis. - This species is distinguished from ingens Wood by the smaller size, by the less deeply impressed, wider striae, and by the broad, very shallowly impressed male frons with the lateral margins less strongly elevated on the upper third.

Male.- Length $2.0-2.3 \mathrm{~mm}, 1.7$ times as long as wide; color dark brown.

Frons broadly, irregularly flattened, lateral margins weakly elevated, a pair of very small, very obscure granules below level of antennal insertion; surface rather coarsely reticulate, punctures minute; vestiture short, inconspicuous.

Pronotum 0.8 times as long as wide; widest behind middle, sides strongly arcuate, moderately constricted behind narrowly rounded anterior margin; surface strongly reticulate, dull, with rather numerous small, isolated asperities uniformly distributed, except median basal area with fine, shallow punctures; vestiture consisting of sparse, slender scales.

Elytra 1.1 times as long as wide, 1.6 times as long as pronotum; scutellum as
wide as long; basal margins each armed by 15 crenulations; sides straight and parallel on slightly more than basal half, broadly rounded behind; striae moderately impressed, punctures rather large, deep; interstriae wider than striae, essentially smooth, punelures very fine, each with a uniseriate row of coarse crenulate tubercles, each about half as wide as interstriae, interstriae 2 with double row of tubercles at base. Declivity steep, convex; declivital granules smaller than on disc. Vestiture consisting of small! scales on posterior part of disc and on declivity, each scale longer than wide; and median rows of erect, interstrial bristles, each bristle slightly shorter than distance between rows of bristles.

Female.- Similar to male except lateral margins of frons not elevated.

## Distribution.-Guatemala.

GUatemala: Volcán Pacaya. Esquintla, I-VI-64, 1300 m , tree seedling, S. L. Wood.

Biology.- Specimens were extracted from new tunnels in the cambium region of twigs less than 1 cm in diameter.

Notes. - The above treatment was based on the type series of 13 specimens.

## 14. Chramesus quadridens Wood Fig. 98

Chramesus quadridens Wood, 1956, Canadian Ent. 88:256 (Holotype, male; Atlixco, Puebla, Mexico: Snow Ant. Coll., Univ. Kansas)
Diagnosis.- This species is distinguished from pumilus (Chapuis), with some difficulty, by characters summarized in the above key. The primary reasons for maintaining it as a distinct species are the distinctly larger size and the habits.

Male.- Length $2.0-2.2 \mathrm{~mm}, 1.6$ times as long as wide; color almost black.

Essentially as in pumilus except lateral margins of male frons usually more strongly elevated, frontal impression usually attaining upper level of eyes; pronotal punctures tending to be larger, deeper, more numerous; elytral ground vestiture tending to be slightly longer, each scale two to four times as long as wide, erect bristles stouter, usually less than half as long as distance between rows.

Female.-Similar to male except frons weakly convex, unarmed.
Distribution.- Puebla.
MEXICO: Puebla: 11 km S Atlixco, 13-VII-53, No. 101, S. L. Wood.

Biology.- Adult specimens and larvae were taken from axial pith tunnels in stems about 5 mm in diameter. The host was a climbing vine, having three leaflets on each leaf; the general character of the stem was quite unlike Canavalia.

Notes.- The above treatment was based on four paratypes.

Mexican specimens of pumilus do not exceed 1.8 mm in length, and characters of body sculpture and vestiture are distinct. The larger specimens and those approaching anatomical similarity to quadridens are from the area south of Guatemala.

## 15. Chramesus pumilus (Chapuis)

Rhopalopleurus pumilus Chapuis, 1869, Synopsis des Scolytides, p. 47 (Holotype, male; Teapa, Tabasco. Mexico; Brussels Mus.)
Chramesus tumidulus Blandford, 1897, Biol. Centr. Amer.. Coleopt. 4(6):170 (Lectotype, female; Las Mercedes, Guatemala, male Bugaba, Panama; British Mus. Nat. Hist., subsequent designation by Wood, 1971, Great Basin Nat. 31:143. Synonymy
Chramesus panamensis Blackman, 1943 Proc. U.S. Nat. Mus. 94:391 (Holotype, female; Panama Canal Zone; U.S. Nat. Mus., 56569); Wood, 1971, Great Basin Nat. 31:143. Synonymy
Chramesus mexicanus Schedl, 1949, Rev. Brasil Biol 9:264 (Holotype, female; Comitán, Chiapas, Mexico: Schedl Coll.); Wood, 1971, Great Basin Nat. 31:143. Synonymy
Diagnosis. - This is a common, widely distributed, somewhat variable species. Except for the doubtfully distinct quadridens Wood, its closest known relatives occur in South America. The two pairs of denticles arming the lateral margins of the male frons distinguish it from most species; characters summarized in the above key distinguish it from quadridens.

Male. - Length $1.4-2.0 \mathrm{~mm}, 1.7$ times as long as wide; color dark brown to almost black, vestiture pale.

Frons rather deeply, broadly concave from epistoma to a point just below upper level of eyes; lateral margins acute on lower twothirds, armed by two pairs of tubercles at and just below level of antennal insertion; surface
finely rugose-reticulate, more nearly reticulate on lower fourth, a few minute, obscure punctures evident below, sparse, fine granules above; vestiture fine, sparse, inconspicuous. Antennal club large, 2.4 times as long as wide.

Pronotum 0.74 times as long as wide; widest one-third legnth from base, sides strongly arcuate, converging toward conspicuous constriction just before rather broadly rounded anterior margin; surface dull, reticulate, small asperities and small shallow punctures about equally abundant, distributed over entire surface, punctures predominate in posteromedian area, asperities in anterolateral areas; vestiture of moderatley short, very stout bristles, a few fine hairs intermixed.

Elytra 1.1 times as long as wide, 1.6 times as long as pronotum; basal margins each armed by 13 crenulations; sides straight and parallel on slightly more than basal half, broadly rounded behind; striae weakly impressed at base, moderately toward declivity, punctures rather coarse, deep; interstriae about one and one-half times as wide as striae, slightly convex, shining, with minute obscure punctures and each with a uniseriate row of coarse, rather close tubercles, each tubercle not more than half as wide as interstriae. Declivity convex, rather steep; striae and interstriae slightly narrower than on disc, tubercles narrower and more widely spaced. Vestiture of small, fringed ground scales, each little longer than wide (longer than this south of Honduras); and interstrial rows of erect bristles, each bristle two-thirds as long as distance between rows, separated within a row by length of a bristle.

Female.-Similar to male except frons feebly convex, lateral margins neither elevated nor armed; pronotal asperities and elytral tubercles usually slightly longer.

Distribution. - Nayarit to Panama.
MEXICO: Chiapas, Jalisco, Michoacán, Nayarit, Tabasco. CENTRAL AMERICA: Costa Rica, Guatemala, Honduras, Panama.

Host.- Canavalia villosa.
Brology. - This monogamous species attacks the stems of wild bean vines larger than 5 mm in diameter. The egg gallery tends to spiral diagonally in the cambium region of smaller stems; it is more nearly transverse in
larger stems. The larval mines are irregular and may consume any portion of the stem.

Notes.- The above treatment was based on the types of pumilus, tumidulus, mexicanus and panamensis and on 221 other specimens. Because Blandford's species was named from two syntypes, I here designate the female, from Las Mercedes, Guatemala, as the lectotype of tumidulus Blandford.

Specimens from Costa Rica and Panama tend to have scales in the elytral ground vestiture very slightly more slender than those from the northern part of the distribution; the erect bristles may also be slightly longer.

## 16. Chramesus aquilus Wood

Chramesus aquilus Wood, 1974, Brigham Young Univ. Sci. Bull, Biol. Ser. 19(1): 10 (Holotype, male; 13 km N Ocasingo, Chiapas, Mexico; Canadian Nat. Coll.)
Diagnosis.- Among Central American forms this species is most nearly allied to demissus Wood, but it is distinguished by the more deeply concave male frons with the lateral margins more strongly elevated, by the more distinctly punctured pronotal disc, by the more rounded interstrial tubercles, and by the different elytral vestiture.

Male.-Length $1.5-1.8 \mathrm{~mm}, 1.5$ times as long as wide; color black, vestiture pale.

Frons broadly, rather deeply concave from epistoma to slightly below upper level of eyes, lateral margins acutely, rather strongly elevated with highest point just below level of antennal insertion, devoid of denticles; surface strongly reticulate, smooth on epistoma, minute, obscure punctures on upper half of concavity; vestiture inconspicuous. Antennal club large.

Pronotum as in demissus except granules smaller, posterior fourth in median area with sparse, shallow, moderately large punctures. Vestiture slightly more slender than in demissus.

Elytra 1.02 times as long as wide; sides almost straight and parallel on slightly more than basal half, broadly rounded behind; basal margins each armed by 11 crenulations, one or more submarginal crenulations on interstriae $2-5$; striae strongly impressed, punctures moderately coarse, deep; interstriae about one and one-half times as wide as striae, moderately convex, smooth, with rows
of rather large, narrowly rounded tubercles, tubercles somewhat confused on 2 and 3. Declivity rather steep, convex; sculpture about as on disc. Vestiture of ground cover of rows of scales on both margins of each interstriae, each scale up to twice as long as wide; and erect bristles in interstrial rows except moderately confused on 2 and 3 on disc, each bristle two-thirds as long as distance between rows, spaced within a row by length of a bristle, each about eight times as long as wide, equal in width to scales in ground cover.
Female.-Similar to male except frons weakly convex, lateral margins rounded; pronotal granules absent, entire surface with shallow, sparse punctures of moderate size.

Distribution. - Chiapas.
MEXICO: Chiapas: 13 km N Ocosingo, 2-VI-69, D. E. Bright.

Notes.- The above treatment was based on the type series of 12 specimens.

## 17. Chramesus signatipennis Schedl

Chramesus signatipennis Schedl, 1962, Mitt. Münchn. Ent. Ges. 52:97 (Holotype, female; Hamburgfarm on Río Reventazon, Limón, Costa Rica; Schedl Coll.)
Diagnosis. - The unique female holotype is distinguished from denticulatus Wood by the slightly larger size, by the stouter body form, by the slightly larger, deeper strial punctures, by the smooth (not reticulate) surfaces of striae and interstriae on the elytral declivity, and by the near absence of granules on the female frons.

Female.- Length $1.4 \mathrm{~mm}, 1.9$ times as long as wide; color yellowish brown.

Frons as in denticulatus except granules virtually absent, reticulate. Antennal club small (partly concealed); apparently as in denticulatus.

Pronotum 0.76 times as long as wide; as in denticulatus; surface strongly reticulate, punctures moderately coarse, obscure; vestiture short, of about equal numbers of slender hairs and stout bristles as in denticulatus.

Elytra 1.3 times as long as wide, 1.8 times as long as pronotum; basically as in denticulatus except strial punctures slightly larger and deeper and surfaces smooth and shining (not reticulate) on disc and declivity; vestiture as in denticulatus and as described in
above key except slightly more abundant and stouter.

Male.- Unknown; characters cited in above key were based on male of denticulatus.

Distribution.- Costa Rica.
COSTA RICA: Hamburgfarm on Río Reventazon, Limón, 1-XI-34, at light, F. Nevermann.

Bıology. - The very closely allied denticulatus was taken from stems $1-2 \mathrm{~cm}$ in diameter of a Bignoniaceae vine. Superficially identical vines occur throughout the lowland forests of Costa Rica and could serve as the host of this species.

Notes. - The above treatment was based on the holotype.

## 18. Chramesus subopacus Schaeffer

 Figs. 97, 98Chramesus subopacus Schaeffer, 1908, J. New York Ent. Soc. 16:221 (Lectotype, female; Huachuca Mits., Arizona; U.S. Nat. Mus., 42934, subsequent designation by Blackman, 1938, J. Washington Acad. Sci. 28:541)
Chramesus canus Blackman, 1938, J. Washington Acad. Sci. 28:541 (Holotype, female; Tallulah, Louisiana; U.S. Nat. Mus., 43641); Wood, 1971, Great Bäsin Nat. 31:143. Synonymy
Diagnosis.- The male frons of this species is unique in having the lateral margins very strongly, evenly elevated to a level well above the level of antennal insertion; this elevation ends precipitously in a small tubercle directed dorsad. The large size and small, weakly impressed strial punctures also serve as distinguishing features.

Male.- Length $1.7-2.4 \mathrm{~mm}, 1.6$ times as long as wide; color dark brown to almost black.

Frons rather deeply, broadly concave from epistomal margin to well above eyes; lateral margins elevated, acutely, very strongly elevated on lower half to a point well above level of antennal insertion, strongly elevated portion ending abruptly at this pointed tubercle or angle; surface finely rugosereticulate above, becoming smooth toward epistoma. Antennal club very large, 2.4 times as long as wide.

Pronotum 0.75 times as long as wide; widest near base, sides strongly arcuate, converging anteriorly to slight constriction just before broadly rounded anterior margin; obscurely reticulate, punctures fine, rather
close, not always clearly defined, their anterior margins usually very feebly raised to form a fine granule, a few of those in anterolateral areas asperate, granules absent in posteromedian area; vestiture of short, very stout bristles, a few fine hairs intermixed.

Elytra 1.0 times as long as wide, 1.4 times as long as pronotum; basal margins each armed by 10 crenulations; sides almost straight and parallel on basal half, broadly rounded behind; striae weakly impressed, punctures very small, shallow; interstriae three or more times as wide as striae, feebly convex, punctures minute, confused, each with a median row of slightly larger nongranulate punctures. Declivity convex, steep; essentially as on disc. Vestiture of rather dense, short scales forming a ground cover; each slightly longer than wider; and rows of erect, interstrial bristles, each bristle half as long as distance between rows, separated within a row by distances equal to length of a bristle.

Female.- Similar to male except frons moderately convex, often foveate at center; each interstriae bearing a uniseriate row of granules on disc.

Distribution.-- Florida and Arizona to Honduras.
USA: Arizona: Huachuca Mts. Florida: Alachua Co., 15-1X-76, Celtis laevigata, T. H. Atkinson. Louisiana: Tallulah, 6-11-11, Hunter No. 1984, G. D. Smith. Texas: Brownsville, 26-III-51, Condalia obtusifolia, S. L. Wood; Kennedy, 30-III-51, C. obtusifolia, S. L. Wood; La Grange, 1907, Celtis, W. F. Fiske; San Antonio, 1907, Celtis, W. F. Fiske. MEXICO: Colima: 24 km W Armeria, $30-\mathrm{Vl}-65,40 \mathrm{~m}$, No. 142, Celtis iguanae, S. L. Wood. Oaxaca: 23 km W Tehuantepec, 8-VII-53, C. iguanae, S. L. Wood. Tamualipas: Encinal 15-V1-53, Condalia, S. L. Wood. HONDURAS: Zamorano, Morazán, 18-1V-64, 700 m , No. 506, C. iguanae, S. L. Wood.

Hosts.-Celtis iguanae, Celtis sp., Condalia obtusifolia, C. sp.

Biology.- This monogamous species constructs transverse galleries in cut or dying host material larger than 2 cm in diameter.
Notes. - The above treatment was based on the holotypes of subopacus and canus, on a male paratype of subopacus, on the male allotype of canus, and on 126 other specimens. The Louisiana specimens have the elytra very slightly more slender ( 1.06 times as long as wide), but otherwise they agree completely with specimens from other areas.

19a. Chramesus hicoriae LeConte Figs. 97, 99, 100

Chramesus hicoriae LeConte, 1868, Trans. Amer. Ent. Soc. 2:168 (Holotype, male; Pennsylvania; Mus. Comp. Zool.)
Rhopalopleurus lecontei Chapuis, 1869, Synopsis des Scolytides, p. 46 (Lectotype, male; Amerique Boreale; Brussels Mus., present designation); LeConte, 1876, Proc. Amer. Philos. Soc. 15:375. Synonymy
Diagnosis.- This species is distinguished from asperatus Schaeffer and setosus Wood by the much longer interstrial bristles, by the less extensive male frontal exacavation, by the host, and by the distribution.

Male.- Length $1.5-1.9 \mathrm{~mm}, 1.6$ times as long as wide; color dark brown to almost black.

Frons broadly, rather deeply concave from epistoma to upper level of eyes; lateral margins acutely elevated, armed by a pair of small teeth just below level of antennal insertion; surface strongly reticulate, punctures fine, close, obscure; vestiture fine, sparse, inconspicuous. Antennal club large, 2.4 times as long as wide.

Pronotum 0.74 times as long as wide; posterior margin bisinuate, median area moderately produced behind; sides widest near base, arcuately converging to a slight constriction just before rather broadly rounded anterior margin; surface reticulate, small, isolated asperities in median area, becoming larger laterally, asperities in posteromedian area usually replaced by a few fine punctures; vestiture of stout, rather short bristles intermixed with less abundant hair.

Elytra 1.0 times as long as wide, 1.5 times as long as pronotum; anterior margins each armed by 9 crenulations; sides almost straight and parallel on basal half, broadly rounded behind; striae weakly impressed, punctures very fine, moderately deep; interstriae feebly convex, almost smooth, punctures very fine, confused, a median row on each interstriae slightly larger and weakly granulate. Declivity steep, convex; as on disc except striae more distinctly impressed. Vestiture of short, slender scales, each about four or more times as long as wide, oriented in a row on both margins of each interstriae, normally a few supplemental scales between these rows; and
interstrial rows of erect blunt bristles, each bristle slightly longer than distance between rows, slightly closer than this within a row.

Female.- Similar to male except frons weakly, irregularly convex, lateral margins neither elevated nor armed; pronotal tubercles and interstrial granules larger.

Distribution.- Wisconsin, E Kansas, and E Texas to Quebec and Georgia.

CANADA: Ontario, Quebec. USA: Connecticut, Delaware, District of Columbia, Georgia, Illinois, lowa, Kansas, Maryland, Massachusetts, Mississippi, Missouri, New Jersey, New York, North Carolina, Ohio, Pennsylvania, South Carolina, Tennessee, Virginia, Vermont. West Virginia, Wisconsin.

Hosts. - Carya spp.
Biology.- Cut and broken hickory branches are selected for attack. The male constructs the entrance tunnel and turning niche, and the female then makes one simple, longitudinal egg gallery about $1-4 \mathrm{~cm}$ long that engraves the wood rather deeply. About 15 to 60 eggs (Blackman 1921:51) are deposited in niches along the margins in the cambium region. The larval mines engrave both bark and wood; they radiate out from the parental tunnel at right angles, then gradually curve to parallel the grain of wood. In small twigs with thin bark, larval mines cut progressively more deeply into the wood. Blackman recorded one generation each year in northern areas, but suggested that two generations might be completed in the southern part of the distribution.

Notes. - The above treatment was based on the types of hicoriae and lecontei and on 346 other specimens. From the three male syntypes in the Brussels Museum, the second specimen is here designated as the lectotype for lecontei Chapuis.

## 19b. Chramesus atkinsoni Wood

Chramesus atkinsoni Wood, 1981, Great Basin Nat. 41:123 (Holotype, male; Cerro Chipinque, Monterrey, Nuevo León, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from hickoriae LeConte by the different elytral vestiture as described below and by other minor characters.

Male.- Length $1.6-1.8 \mathrm{~mm}, 1.5$ times as long as wide; color very dark brown.

Frons similar to hickoriae except excavated area very slightly wider in proportion to its length (length/width $=1.36$ compared to 1.42).

Pronotum similar to hickoriae except more strongly convex (female does not differ in this character).

Fig. 99. Scolytidae spp.: 25, Chramesus hickoriae; 26, Chramesus chapuisii, 27, Carphoborus bifurcus; 28, Hylesimus aculeatns; 29, Hypothenemus dissimilis; 30, Hypothenemus rotundicollis. (After Blackman 1922: pl. V.)

Elytra similar to hickoriae except interstrial setae in ground cover (forming rows at each interstrial margin) more slender, erect bristles stouter and much shorter, bristles spaced between rows by three-fourths length of a bristle, by length of a bristle within a row (bristles slightly longer than either distance in hickoriae); each bristle about eight times as long as wide.

Female.- Similar to male except frons convex and unarmed by a pair of tubercles; pronotum more strongly convex and with asperities averaging larger.

Distribution. - Nuevo León.
MEXICO: Nuevo León: Cerro Chipinque, Monterrey, 31-V-80. 1350 m, No. S-021, Persea, T. H. Atkinson.

Notes. - The above treatment was based on the type series of four specimens.

## 20. Chramesus marginatus Wood

Chramesus marginatus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):11 (Holotype, male; "Mexico"; U.S. Nat. Mus.)
Diagnosis.- This species is distinguished from setosus Wood by the larger size, by the larger number of submarginal crenulations on the elytral bases, particularly on interstriae 2 , by the presence of interstrial rows of tubercles on the male elytra, and by the smaller, less numerous crenulations on the pronotum.

Male.- Length $2.5 \mathrm{~cm}, 1.65$ times as long as wide; color dark brown, vestiture pale.

Frons similar to setosus but not as deeply concave on upper half, punctures on upper half slightly larger. Pronotum outline as in setosus; surface reticulate, a few asperities in lateral areas, a few minute granules on median part of anterior third, punctures small, moderately close, very shallow on anterior half, somewhat deeper in posterior area. Vestiture of short, slender bristles of moderate abundance.

Elytral outline and basal armature as in setosus; striae distinctly impressed, punctures very small, moderately deep; interstriae at least four times as wide as striae, weakly convex, smooth, with a central row of fine granules and a row of minute punctures on each margin. Declivity rather steep, broadly convex; sculpture as on disc. Vestiture of sparse, short, erect, slender, bristlelike, ground cover arranged in approximate rows on margins of
interstriae, and rows of interstrial bristles arising from granules, each bristle twice as long as ground cover, two-thirds as long as distance between rows, as long as distance between setae within a row.

Female.-Similar to male except frons weakly convex, its lateral margins not elevated or armed; pronotal asperities larger; interstrial tubercles slightly larger.

Distribution.- "Mexico."
MEXICO: Intercepted at Brownsville, Texas, 26-I-49, 67:333. in dead wood coming from Mexico, 49-2948, D. J.
Smith.

Notes. - The above treatment was based on the type series of three specimens.

## 21. Chramesus setosus Wood

## Chramesus setosus Wood, 1960. Great Basin Nat. 20:61 (Holotype. male: Madera Canyon. Santa Cruz Co., Arizona; Wood Coll.)

Diagnosis.- This species is distinguished from asperatus Schaeffer, by the much more slender elytral setae, both ground cover and bristles, by the finer elytral punctures, and by the host.

Male.- Length $1.2-1.8 \mathrm{~mm}, 1.5$ times as long as wide; color almost black.

Except for the slightly coarser sculpture and much finer vestiture, this species is as in asperatus. The two species were taken side by side in their respective hosts at Oak Creek Canyon, where they clearly maintained their specific identities.

Distribution.- Arizona and Chihuahua.
USA: Arizona: Madera Canyon in Santa Cruz Co., 1-VIII-60, Rhamnus betulaefolia, S. L. Wood; Oak Creek Canyon in Coconino Co., 30-VII-60, 11-VI-69, R. betuluefolia, S. L. Wood; Bear Canyon in Santa Catalina Mits., I5-VIII-68, Rhumnus, D. E. Bright; Cave Creek in Chiricahua Mts., 20-VII-68, Rhamnus, D. E. Bright; Mingus MIts., 23-VIII-68. Rhamnus, D. E. Bright. MEXICO: Chihuahua: Colonia Juárez, 22-VII-60, Morus alba,
S. L. Wood.

Hosts.- Rhamnus betulaefolia, Morus alba.

Biology.- Essentially as in asperatus.
Notes. - The above treatment was based on the type series of 186 specimens and on 98 additional specimens.

## 22. Chramesus asperatus Schaeffer Fig. 97

Chramesus asperatus Schaeffer, 1908, J. New York Ent. Soc. 16:220 (Lectotype, female; Chiricahua Atts., Arizona: U.S. Nat. Mus., 42486, subsequent
designation by Blackman, 1938, J. Washington Acad. Sci. 28:5:39)
Chramesus gibber Blackman, 1938, J. Washington Acad. Sci. 28:541 (Holotype, female; Clouderoft, New Mexico; U.S. Nat. Mus. 43143); Wood, 1971. Great Basin Nat. 31:143. Synonymy
Diagnosis.- This species is distinguished from the very closely related setosus Wood by the much stouter elytral ground setae and bristles, by the slightly coarser elytral punctures, and by the host.

Male.- Length 1.4-1.9 mm, 1.5 times as long as wide; color almost black.

Frons as in hicoriae except excavated area extending well above upper level of eyes. Antennal club large, 2.6 times as long as wide.

Pronotum 0.73 times as long as wide; as in hicoriae except posteromedian punctured area somewhat more extensive, punctures slightly larger, deeper.

Elytra as in hicoriae except strial punctures slightly larger, deeper; interstriae three or more times as wide as striae; ground vestiture apparently more abundant, stouter, each scale two to four times as long as wide; erect bristles stouter, about as wide as ground scales, each equal in length to or slightly
shorter than distance between rows of bristles.

Female.-Similar to male except frons convex, lateral margins not elevated or armed; pronotal asperities and interstrial tubercles larger.

Distribution.-Arizona to New Mexico.
USA: Arizona: Chiricahua Mts., Flagstaff, Grand Canyon, Huachuca Mts., Kaibab N.F., Mt. Bigelow in Santa Catalina Mits., Parmalee Pinaleno Mits., Prescott, Sedonia, Williams. New Mexico: Cloudcroft, Coolidge, Sandia Mts., Vermejo.

## Host.- Robinia neomexicana.

Brology.- This monogamous species constructs transverse egg galleries in the cambium region of cut, broken, or unthrifty host material usually smaller than 5 cm in diameter. The larval mines wander in the phloem tissues until just before pupation, when they cut more deeply into the wood.

Notes. - The above treatment was based on the male lectoparatype of asperatus, on the female holotype and male allotype of gibber, and on 505 additional specimens. Most of the specimens from New Mexico have the vestiture very slightly stouter than those from Arizona, but the difference is neither

Fig. 100. Chramesus spp., galleries; 75, hickoriae; 76, chapuisii. (After Blackman 1922: pl. XV11.)
consistent nor significant; those from the Chiricahua Mountains tend to be intermediate with respect to this character.

## 23. Chramesus strigatus Wood

Chramesus striatus Wood, 1956 (nee Eggers, 1943), Canadian Ent. 88:256 (Holotype, male; Atlixco, Puebla, Mexico; Snow Ent. Coll., Univ. Kansas)
Chramesus strigatus Wood, 1960, Great Basin Nat. 20:62 (Replacement name)
$\mathrm{D}_{\text {Iagnosis.- This species is distinguished }}$ from asperatus Schaeffer by the rather closely, transversely strigose proepimeral area, by the much coarser strial punctures, and by the near absence of interstrial granules in both sexes.

Male.- Length $1.4-1.8 \mathrm{~mm}, 1.6$ times as long as wide; color dark brown to black.

Frons and pronotum essentially as in asperatus; antennal club 2.4 times as long as wide; propleural area strongly strigose, about eight transverse (vertical) ridges separated by grooves.

Elytra about 1.0 times as long as wide, 1.6 times as long as pronotum; basal margins each armed by eight coarse crenulations; outline as in asperatus; striae weakly impressed, stronger toward declivity, punctures moderately coarse, deep; interstriae not more than twice as wide as striae, punctures rather fine, confused, none granulate. Declivity convex, rather steep; essentially as on disc.
Female.- Similar to male except frons weakly convex with a slight transverse impression just above epistoma; median row of granules on each interstriae very feebly granulate (about as in male asperatus).

Distribution.-Puebla.
MEXICO: Puebla: 11 km S Atlixco, 13-VII-53, Acacia, S. L. Wood.

Biology.- The newly formed egg galleries of this monogamous species cut deeply into the wood of branches less than 3 cm in
diameter.

Notes. - The above treatment was based on six paratypes.

## 24. Chramesus punctatus Wood

Chramesus punctatus Wood, 1967, Great Basin Nat. 27:94 (Holotype, male; Volcán Pacaya, Esquintla, Guatemala; Wood Coll.)
Diagnosis.- This species is allied, but not closely related, to demissus Wood and vastus

Wood; it is distinguished by the very coarse strial punctures and interstrial granules, by the longer declivital bristles (except these are absent on interstriae 2), and by the deeper male frontal excavation.

Male.- Length $1.5-2.1 \mathrm{~mm}, 1.7$ times as long as wide; color dark brown.

Frons broadly, rather deeply excavated from upper level of eyes to epistoma; lateral margins rather strongly, acutely elevated, armed just below level of antennal insertion by a pair of small tubercles; epistomal premandibular lobe long and narrow; surface reticulate, finely, obscurely punctured; vestiture inconspicuous. Antennal scape ornamented by a small tuft of hair.

Pronotum 0.80 times as long as wide; widest on basal fourth, sides moderately arcuate, feebly constricted just behind narrowly rounded anterior margin; surface reticulate, dull, with numerous small, isolated, shining asperities, posteromedian area with a few small punctures; vestiture consisting of short, stout, semirecumbent bristles.

Elytra 1.1 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on more than basal half, broadly rounded behind; basal margins each armed by about 12 crenulations; striae moderately impressed, punctures very large, deep; interstriae about as wide as striae, convex, irregular, punctures minute, each interstriae with a row of very coarse, isolated tubercles. Declivity moderately steep, broadly convex; striae and interstriae somewhat narrower; interstriae 2 and 4 devoid of tubercles (some paratypes with one or more on each). Vestiture consisting of numerous small scales on declivity, and median interstrial rows of erect bristles from base to apex; each bristle as long as distance between rows of bristles and between adjacent bristles in a row; declivital interstriae 1 and 4 (usually) devoid of bristles (in a few specimens both bear one or more bristles).
Female.- Similar to male except frons weakly convex, lateral margins not elevated or armed, a slight transverse impression just above epistoma.

## Distribution.- Guatemala.

GUATEMALA: Guatemala City, 30-V-64, S. L. Wood; Volcán Pacaya, Esquintla, 1-VI-64, S. L. Wood. Both taken from the same host species.

Host.- Probably Canavalia sp.

Biology.- This species attacked recently cut vines larger than 1 cm in diameter. The egg galleries were transverse; larval mines apparently wandered at random.

Notes.- The type series of 121 specimens was used to prepare the above treatment.

## 25. Chramesus vastus Wood

Chramesus tastus Wood, 1967, Great Basin Nat. 27:92 (Holotype, male; Cerro Punta, Chiriquí, Panama; Wood Coll.)
Diagnosis.- This species is distinguished from all others in the genus by the large size, by the sculpture and hairlike vestiture of the pronotum, and by the scalelike ground vestiture of the elytra with median interstrial rows of longer, hairlike setae.

Male.- Length 2.4-2.7 mm, 1.7 times as long as wide; color dark brown.

Frons broadly, shallowly excavated from epistoma to a point well below upper level of eyes, lateral margins acutely, rather strongly elevated and armed just below level of antennal insertion by a pair of tubercles; epistomal margin slightly elevated; surface rugose-reticulate, with fine punctures on marginal areas; vestiture inconspicuous.

Pronotum 0.8 times as long as wide; widest just behind middle, sides strongly arcuate, moderately constricted just behind anterior margin, broadly rounded in front; surface reticulate, dull, with rather numerous small, isolated, shining asperities uniformly distributed from base to anterior margin except small and sparse in posteromedian area; vestiture consisting of short, sparse, coarse hair.

Elytra 1.1 times as long as wide, 1.6 times as long as pronotum; sides straight and parallel on basal half, broadly rounded behind; basal margins each armed by 10 crenulations; striae 1 and 2 deeply, others moderately impressed, punctures small, occasionally subconfluent on 1 and 2; interstriae about one and one-half times as wide as striae, weakly convex, punctures shallow, minute, confused, each interstriae with a median row of large tubercles except small on base of 1 and often a partial double row at base of 2 . Declivity rather steep, convex; striae and interstriae narrower than on disc; tubercles narrower and higher, except absent on lower half of interstriae 1 and 2. Vestiture consisting of very
small, abundant scales, each scale slightly longer than wide except hairlike along suture, and median rows of erect interstrial, hairlike bristles, each bristle slightly shorter than distance between rows.

Female.- Similar to male except frons convex; pronotum with punctures on disc impressed and feebly or not at all asperate toward base, lateral areas more strongly asperate; elytral striae more deeply impressed, interstrial tubercles continuing to apex on 1 and 2.

## Distribution.- Panama.

Panama: Cerro Punta, Chiriquí, 11-19-I-64, 2000 m , Nos. 315, 348, 371, 376, Inga sp., S. L. Wood.

Brology.- This monogamous species attacked cut or unthrifty limbs and branches up to about 10 cm in diameter. The subtransverse parental galleries penetrated directly into the sapwood; the larvae evidently spent their entire period of development in the sapwood.

Notes.- The above treatment was based on the type series of 19 specimens.

## 26. Chramesus vitiosus Wood

Chramesus ritiosus Wood, 1969, Great Basin Nat. 29:125 (Holotype, male; Rosamorada, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from the closely related crenatus Wood by the shorter, erect, interstrial bristles, by the complete absence of male strial punctures, and by the greater distribution of pronotal punctures.

Male.- Length $1.2-1.5 \mathrm{~mm}, 1.4$ times as long as wide; color very dark brown, vestiture pale.

Frons broadly, deeply concave from epistoma to well above eyes, lateral margins acutely, strongly elevated, attaining a subserrate summit at level of antennal insertion, lower tubercle usually predominating; surface shining, finely reticulate, punctures not clearly evident; vestiture fine, inconspicuous. Antennal club moderately large, 2.3 times as long as wide.

Pronotum 0.72 times as long as wide; widest on basal fourth, sides arcuately converging to slight constriction just before rather broadly rounded anterior margin; surface subreticulate, rather closely asperate, asperities largely replaced by fine punctures in
posteromedian area, a few punctures occur almost to anterior margin in median area; vestiture of moderately abundant, short, stout, pale bristles over entire surface.

Elytra 0.91 times as long as wide, 1.4 times as long as pronotum; basal margins each armed by about 12 partly contiguous, low crenulations; sides straight and parallel on less than basal half, broadly rounded behind; striae distinctly impressed, glabrous, punctures obsolete; interstriae as wide as striae, almost smooth, small punctures close, confused. Declivity convex, rather steep; a few strial punctures obscurely present. Vestiture consisting of a ground cover of closely set, short scales, each scale about twice as long as wide; and interstrial rows of erect scalelike bristles, each bristle not more than twice as long as ground scales, about half as long as distance between rows or between bristles within a row.

Female.- Similar to male except frons weakly convex, foveate at center, a weak, transverse impression just above epistoma; punctures on pronotum slightly coarser and more widely distributed; strial punctures small, distinctly impressed; occasional very small interstrial granules evident; scales in interstrial ground cover only slightly longer than wide.

## Distribution.- Nayarit.

MEXICO: Nayarit: Los Corchos, 10 -vil-65, 10 m , No. 211, Inga paterno. S. L. Wood; 48 km N Rosamorada, 15-VII-65, $100 \mathrm{~m}, ~$ No. $255,8 \mathrm{~km}$ S, 14-VII-65, 100 m , No. 248, Inga paterno, S. L. Wood.

Biology.- This monogamous species was taken from longitudinal egg galleries in dying branches up to 10 cm in diameter.

Notes.- The above treatment was prepared from the type series of 65 specimens.

## 27. Chramesus wisteriae Wood

Chramesus wisteriae Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):11 (Holotype, male; Bay St. Louis, Mississippi; U.S. Nat. Mus.)
Diagnosis. - This species is distinguished from chapuisi LeConte by the smaller tuft of hair on the male scape, by the less strongly impressed male frons, by the presence of interstrial tubercles on the male elytra, and by the slightly shorter elytral bristles in both
sexes.

Male.- Length $1.6-1.8 \mathrm{~mm}, 1.6$ times as long as wide; color very dark brown, vestiture pale.
Frons as in acacicolens except surface with sparse, minutely granulate, small, obscure punctures. Pronotum as in acacicolens except granules evidently smaller, less conspicuous, punctures much larger, deeper, closer, punctures discernible from base to anterior fourth; vestiture slightly more abundant.

Elytra 1.2 times as long as wide; as in acacicolens except striae weakly impressed, punctures larger, more distinctly impressed; interstriae slightly less than twice as wide as striae; erect interstrial bristles very slightly shorter and more slender than in acacicolens, each bristle six to eight times as long as wide, half as long as distance between rows.

Female. - Similar to male except frons weakly convex, lateral margins not elevated or armed, foveate at center; pronotal asperities in lateral areas larger; interstrial tubercles distinctly larger.

Distribution.- Mississippi.
USA: Mississippi: Bay St. Louis, 12-V-45, Wisteria, 459773, presumably taken by W. H. Anderson.

Notes.- The above treatment was based on the type series of five specimens.

## 28. Chramesus chapuisi LeConte

Figs. 97, 99, 100
Chramesus chapuisi LeConte, 1876, Proc. Amer. Philos. Soc. 15:375 (Holotype, female; Louisiana; Mus. Comp. Zool.)
Diagnosis.- This species is allied to periosus Wood, but it is distinguished by the smaller size, by the smaller, stouter antennal club, and by the tuft of hair on the male scape.

Male.- Length $1.5-2.0 \mathrm{~mm}, 1.7$ times as long as wide; color dark brown.

Frons broadly, deeply concave from epistoma to above upper level of eyes, lateral margins acutely elevated and armed by a pair of small teeth just below level of antennal insertion; surface reticulate, with fine, obscure punctures; vestiture rather fine, inconspicuous. Antennal scape bearing a large tuft of long yellow hair; club 2.2-2.4 times as long as wide.

Pronotum 0.76 times as long as wide; outline as in related species; surface reticulate (somewhat obscure) with isolated asperities
over entire surface except partly or entirely replaced by moderately fine punctures in posteromedian area (somewhat variable within a series), asperities rather coarse laterally; vestiture of mixed stout bristles and fine hair of moderate length.

Elytra 1.05 times as long as wide, 1.5 times as long as pronotum; anterior margins each armed by 11 crenulations; sides almost straight and subparallel on slightly more than basal half, rather broadly rounded behind; striae weakly impressed, punctures rather small, deep; interstriae about two and onehalf times as wide as striae, feebly convex, smooth with a few very minute points, punctures fine, confused, none granulate. Declivity convex, steep; striae, particularly 1 , somewhat more strongly impressed, otherwise essentially as on disc. Vestiture consisting of ground cover of rather abundant, confused scales, each scale about twice as long as wide except near suture; and erect, interstrial rows of rather slender bristles, each slightly shorter than distance between rows, spaced within a row by slightly shorter distances.

Female.- Similar to male except frons irregularly, weakly convex, foveate at center; tuft of hair on antennal scape greatly reduced or absent; pronotal asperities slightly coarser; each interstriae with a median row of pointed tubercles.

Distribution.-Kansas and Pennsylvania to San Luis Potosí and Florida.
USA: Florida, Kansas, Louisiana, Maryland, Mississippi, Pennsylvania, Texas. MEXICO: San Luis Potosí.

Hosts.-Celtis occidentalis, C. sp., and possibly Robinia.

Biology. - Small, cut, broken or unthrifty branches are selected for attack. The egg galleries are from $1-3 \mathrm{~cm}$ long, longitudinal, and engrave the wood rather deeply. Larval mines radiate out from the parental tunnel and usually gradually curve to parallel the grain of the wood.

Notes.- The above treatment was based on the holotype and on 465 other specimens. The holotype is a female, not a male, as has been reported.

## 29. Chramesus periosus Wood

Chramesus periosus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):5 (Holotype, male; Jáltipan, Veracruz, Mexico; Wood Coll.)

Diagnosis.- This species is distinguished from crenatus Wood by the larger size, by the larger number of fused crenulations on the elytral bases, and by other characters.

Male.- Length $2.0-2.5 \mathrm{~mm}, 1.4$ times as long as wide; color brown.

Frons broadly concave from epistomal margin to upper level of eyes; lateral margins acutely elevated from well below upper level of eyes to epistomal margin, bearing a pointed tubercle at level of antennal insertion; surface reticulate, obscurely, finely punctured; vestiture fine, inconspicuous. Antennal scape with several hairlike setae; club 2.4 times as long as wide.

Pronotum 0.73 times as long as wide; posterolateral angles one-third pronotum length from base, median area slightly produced posteriorly; sides widest at posterolateral angles, strongly, arcuately convergent to moderate constriction just before rather broadly rounded anterior margin; surface finely reticulate, with fine, moderately deep, rather close punctures, about half of those in central area finely asperate on their anterior margins, asperities larger and more numerous toward anterolateral angles; vestiture consisting of stout, rather short, recumbent bristles and similar, very fine hair.

Elytra 0.90 times as long as wide, 1.4 times as long as pronotum; anterior margins armed by low, basally fused crenulations that merge lateral to striae 4 into a continuous costa; striae moderately impressed, punctures small, moderately deep, rather widely spaced; interstriae about twice as wide as striae, weakly convex, a median row of rather fine nongranulate punctures and many confused minute punctures on each interstriae. Declivity rather steep, convex; sculpture essentially as on disc. Vestiture consisting of ground cover of small nonoverlapping interstrial scales, each slightly longer than wide, and median rows of erect interstrial bristles, each bristle twice as long as ground vestiture and four to five times as long as wide and spaced within a row by slightly more than length of a bristle.

Female.- Similar to male except frons not impressed, almost flat, lateral margins not elevated or armed; lateral asperities on
pronotum coarse, those in posteromedian area somewhat reduced; each interstriae bearing a uniseriate row of coarse, narrow tubercles, each almost as high as wide.

Distribution.- Veracruz.
MEXICO: Veracruz: 5 km W Jáltipan, 25-V1-67, 10 m, No. 99, S. L. Wood.

Host.- A tree awaiting identification.
Biology.- This monogamous species attacked recently cut branches 3 to 8 cm in diameter. The somewhat biramous, transverse parental tunnels extended into the sapwood about 5 mm below the surface. Chramesus crenatus and Scolytus propinguus shared the same host material.

Notes.- The above treatment was based on the type series of 58 specimens.

## 30. Chramesus cariabilis Wood

Chramesus cariabilis Wood. 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):9 (Holotype, male; Lago Catemaco, Veracruz, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from periosus Wood by the smaller size, by the smaller strial punctures, by the bicolored elytral setae, and by the very different male frons.

Male.- Length $1.8-2.3 \mathrm{~mm}, 1.6$ times as long as wide; color dark brown, vestiture forming a slightly variegated pattern in most specimens.

Frons broadly, deeply concave from epistoma to slightly above eyes, lateral margins acutely, rather strongly elevated, armed just above level of antennal insertion by a large triangular dentation; surface reticulate, epistoma and large premandibular lobe smooth, shining; vestiture of sparse, minute hair. Antennal club large.

Pronotum 0.74 times as long as wide; outline as in disparilis; surface finely reticulate, punctures small, shallow, close, spaced by distances equal to diameter of a puncture, devoid of granules. Vestiture of short hair and equal numbers of scales, each scale four to six times as long as wide; central and anterior setae darker.

Elytra 1.05 times as long as wide; sides almost straight and parallel on basal half, broadly rounded behind; 12 pairs of crenulations on basal margins, six submarginal crenulations scattered on bases of interstriae 2-4; striae distinctly impressed, punctures small, rather shallow; interstriae three times as wide as striae, smooth, bristle-bearing punctures small, almost uniseriate, those punctures bearing ground scales minute. Declivity rather steep, convex; sculpture as on disc. Vestiture of ground cover of small scales, each scale one to two times as long as wide; and rows of erect bristles, each bristle about twice as long as ground cover, half as long as distance between rows, as long as distance between bristles within a row, each bristle about six times as long as wide; in an obscure variegated pattern.

Female. - Similar to male except frons weakly convex, lateral margins rounded, unarmed, surface rugose-reticulate; anterolateral areas of pronotum sparsely asperate.

Distribution.- Veracruz.
MEXICO: Veracruz: Lago Catemaco, 16-20-V1-69, D. E. Bright.

Notes.- The above treatment was based on the type series of 26 specimens.

## 31. Chramesus microporosus Wood

Chramesus microporosus Wood, 1974. Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):10 (Holotype, male; El Sumidero, 24 km N Tuxtla Gutierrez. Chiapas, Mexico; Canadian Nat. Coll.)
Diagnosis. - This species is distinguished from periosus Wood by the deeper male frontal concavity that extends slightly above the upper level of the eyes, by the finer pronotal punctures and granules, by the fewer submarginal crenulations on the elytral bases, by the minute strial punctures, by the more slender, nonsubplumose scales of the elytral ground vestiture.

Male.- Length 1.8-2.4 mm, 1.6 times as long as wide; color very dark reddish brown.

Frons as in periosus except concavity extending slightly above eyes, much deeper on upper half. Pronotum as in periosus except punctures less than one-third as large as granules, much smaller and less numerous.
Elytra as in periosus except submarginal crenulations near base of elytra about half as
numerous, strial punctures very minute to entirely obsolete, striae smooth, shining, interstrial punctures also minute; scales in ground cover about four times as long as wide, not subplumose; bristles about three times as long as ground cover, scalelike, each about six to eight times as long as wide.

Female.-Similar to male except frons convex, foveate at center; lateral areas of pronotum asperate; strial punctures very small, but distinctly larger; interstriae each with a row of moderately large, pointed tubercles.

Distribution.- Chiapas.
MEXICO: Chiapas: El Sumidero, 24 km N Tuxtla Gutierrez, 7-VI-69, D. E. Bright.

Notes. - The above treatment was based on the type series of 17 specimens.

## 32. Chramesus xylophagus Wood

Chramesus xylophagus Wood, 1956, Canadian Ent. 88:255 (Holotype, male; Rosario, Sinaloa, Mexico; Snow Ent. Coll., Univ. Kansas)
Diagnosis.- This species is distinguished from crenatus Wood by the larger size, by the slender pronotal setae, by the presence of male interstrial granules, and by the xylophagous habit.

Male.- Length $1.6-1.9 \mathrm{~mm}, 1.6$ times as long as wide; color very dark brown.

Frons broadly, rather deeply concave from epistoma to just above upper level of eyes, lateral margins acutely elevated and armed by a pair of small teeth just below level of antennal insertion; surface minutely reticulate (almost rugose-reticulate), very finely, obscurely punctured; vestiture fine, sparse, inconspicuous. Antennal club 2.6 times as long as wide.

Pronotum 0.75 times as long as wide; widest near base, sides strongly, arcuately convergent to moderate constriction just before broadly rounded anterior margin; surface subreticulate, closely, rather coarsely, deeply punctured, anterior margins of a few anteromedian punctures minutely asperate, anterolateral areas with slightly larger asperities; vestiture of flattened, moderately short bristles, hairlike setae almost absent.

Elytra 1.0 times as long as wide, 1.5 times as long as pronotum; basal margins each armed by 11 crenulations; sides almost straight and parallel on basal half, rather
broadly rounded behind; striae 1 moderately, others weakly impressed, punctures rather coarse, deep; interstriae almost twice as wide as striae, weakly convex, each with a uniseriate row of rounded granules, punctures numerous, minute, confused. Declivity broadly convex, steep; essentially as on disc. Vestiture consisting of ground cover of small, interstrial scales, each slightly longer than wide; and uniseriate rows of erect, flattened bristles, each bristle about three times as long as ground scales, at least five times as long as wide, each about half as long as distance between rows and within a row.

Female.- Similar to male except frons convex, lateral margins not elevated or armed; pronotal asperities and interstrial granules distinctly larger.

Distribution.- Sinaloa to Nayarit.
NEXICO: Nayarit: 8 km S Rosamorada, 14 -V11-65, 100 m , No. 248, Inga paterno, S. L. Wood; 48 km N Rosamorada, 15-VII-65, 100 m , No. 255. Inga paterno, S. L. Wood. Sinaloa: Rosario, 21-VII-53, $40 \mathrm{~m}, \mathrm{~S}$. L. Wood.

Biology. - Broken branches $1-5 \mathrm{~cm}$ in diameter were attacked. The parental tunnels cut deeply into the wood; larval mines were only partly developed, but they tended to follow the grain deep in the wood.

Notes.- The above treatment was based on seven paratypes and on 59 other specimens.

## 33. Chramesus crenatus Wood

Fig. 98
Chramesus crenatus Wood, 1956, Canadian Ent. 88:257 (Holotype, male; Veracruz, Mexico: Snow Ent. Coll., Univ. Kansas)
Diagnosis.- This species is distinguished from the very closely related vitiosus Wood by the longer interstrial bristles, by the presence of distinct strial punctures in the male, and by the more restricted distribution of pronotal punctures.

Male.- Length $1.3-1.6 \mathrm{~mm}, 1.6$ times as long as wide; color very dark brown.

Frons as in vitiosus except with a central fovea. Antennal club 2.0 times as long as wide.

Pronotum 0.75 times as long as wide; as in vitiosus except punctures mostly larger, very shallow, confined to posteromedian fourth, asperities very slightly larger; vestiture of stout and very fine setae intermixed.

Elytra 1.0 times as long as wide, 1.4 times as long as pronotum; as in vitiosus except striae more strongly impressed, punctures small, rather deep, interstriae more strongly convex; scales in ground vestiture wider; erect interstrial bristles much longer, more slender, each bristle at least three times as long as ground scales, almost as long as distance between rows.
Female.-Similar to male except frons convex, foveate; pronotal asperities evidently coarser.

## Distribution.- Veracruz to Yucatán.

MEXICO: Veracruz: Veracruz, 30-V1-53, S. L. Wood; 5 km W' Jaltipan, 25-VI-67, 10 m , No. 99, S. L. Wood. Yucatán: "Yucatán," 23-1II-61, E. J. Davidson.

Biology.- Small branches, up to 4 cm in diameter, of trees cut about three days previously were attacked by this species. The new parental tunnels were transverse, rather deeply engraving wood. This species was associated with Chramesus periosus and Scolytus propinguus in a moderately large tree that awaits identification.

Notes. - The above treatment was based on 138 paratypes and on 72 other specimens.

## 34. Chramesus bicolor Wood

Chramesus bicolor Wood, 1967, Great Basin Nat. 27:91 (Holotype, male; La Lima, Cortez, Honduras: Wood Coll.)
Diagnosis.- This species is distinguished by the unique bicolored pattern of scales.

Male.- Length $1.4-1.7 \mathrm{~mm}, 1.6$ times as long as wide; body color very dark brown, with white scales except dark scales on a subcordate area occupying median third of pronotum anterior to basal fourth, and on elytra a pair of dark areas on posterior half of disc from interstriae 2 to 8 but not extending on declivity.

Frons broadly excavated from epistoma to upper level of eyes, lateral margins acute, armed just below level of antennal insertion by a pair of small teeth; surface strongly reticulate, punctures very fine; vestiture short, sparse.

Pronotum 0.83 times as long as wide; widest at base, sides arcuately converging, then distinctly constricted just behind broadly rounded anterior margin; surface rather coarsely, deeply punctured, dull; surface largely obscured by scalelike vestiture, each
scale at least three times as long as wide, a few fine, slender bristles intermixed.

Elytra 1.0 times as long as wide, 1.3 times as long as pronotum; basal margins each armed by 12 crenulations; sides straight and parallel on basal half, broadly rounded behind; striae moderately impressed, punctures large, rather deep; interstriae slightly wider than striae, moderately convex, punctures squamiferous, confused, median row weakly subvulcanate, largely obscured by vestiture. Declivity steep, convex; sculpture as on disc except striae and interstriae somewhat narrower. Vestiture consisting of short, broad scales, each scale as wide as long; and median interstrial rows of longer erect scales, each about five times as long as wide and almost as long as distance between rows of scales.
Female. - Similar to male except frons weakly convex, lateral margins not elevated, unarmed; anterolateral areas of pronotum more coarsely asperate; interstrial granules slightly larger.
Distribution.- Honduras.
honduras: La Lima, Cortez, 5 -V-64, 50 m , Cestrum scandens, S. L. Wood.

Brology.- This monogamous species attacks stems less than 5 mm in diameter. The diagonal or longitudinal egg galleries are more or less in the cambium region, although in smaller stems they cut rather deeply.

Notes. - The above treatment was based on the type series of 63 specimens.

## 35. Chramesus minulus Wood

Chramesus minulus Wood, 1969, Great Basin Nat. 29:126 (Holotype, female; La Ceiba, Honduras; Wood Coll.)
Diagnosis.- This species is distinguished from acacicolens Wood by the smaller size, by the more slender form, by the much shorter, erect, interstrial scales, and by the stouter pronotal scales.

Female.- Length $1.2-1.3 \mathrm{~mm}, 1.8$ times as long as wide; color yellowish brown.

Frons weakly convex, somewhat flattened on upper half, a slight transverse impression just above epistoma; surface minutely rugu-lose-reticulate, fine punctures indistinct; vestiture short, rather sparse, stout. Antennal club rather small for this genus, 2.0 times as long as wide.

Pronotum 0.80 times as long as wide; widest at base, sides rather weakly arcuate and converging slightly on basal two-thirds, broadly rounded in front; surface rather finely, closely granulate-punctate (largely obscured by scales), becoming finely asperate toward anterolateral angles; vestiture of short, oval almost white scales.

Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; basal margins each armed by 13 crenulations; sides almost straight and parallel on slightly more than basal half, rather broadly rounded behind; striae weakly impressed, punctures coarse, sharply impressed, rather shallow; interstriae about one and one-half times as wide as striae, moderately convex, smooth with minute confused punctures, each interstriae with a median row of very fine granules. Declivity convex, moderately steep; essentially as on disc. Vestiture consisting of a ground cover of short scales, each scale as long as wide, slightly more than a third as wide as an interstriae, and median interstrial rows of erect scales, each only slightly longer than ground scales and mostly about twice as long as wide.

Distribution.-Honduras.
HONDURAS: La Ceiba, Atlantida. 2y-V, 10-VI-49, at light, E. C. Becker.

Notes.- The above treatment was based on the two females in the type series.

## 36. Chramesus acacicolens Wood

Chramesus acacicolens Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 3$ (Holotype, male; Cañas, Guanacaste, Costa Rica; Wood Coll.)
Diagnosis.-A species closely related to minulus Wood, but distinguished by the smaller size, by the less slender body form, by the longer, erect, interstrial scales, and by the more slender pronotal scales.

Male.- Length $1.5-1.8 \mathrm{~mm}, 1.65$ times as long as wide; color light brown.

Frons broadly, concavely excavated from above upper level of eyes to epistoma, deepest point near middle, subfoveate; lateral margins acute below, armed by a pair of tubercles just below level of antennal insertion; surface coarsely reticulate, a few minute punctures scarcely visible; vestiture fine, short, inconspicuous.

Pronotum 0.73 times as long as wide; median basal area slightly produced into scutellar notch, sides widest near base, rather strongly arcuate, constricted just behind broadly rounded anterior margin; surface minutely rugulose, dull, rather finely, shallowly punctured, punctures becoming finely asperate toward anterior and lateral areas; vestiture consisting of short, stout bristles intermixed with similar fine hair.

Elytra 1.07 times as long as wide, 1.6 times as long as pronotum; basal margins each armed by 11 crenulations; sides straight and parallel on basal half, broadly rounded behind; striae impressed, punctures rather large, deep; interstriae about twice as wide as striae, convex, with small, abundant, squamiferous punctures and median rows of small tubercles that decrease in size posteriorly. Declivity convex, moderately steep, as on disc, except tubercles not evident. Vestiture consisting of abundant short scales, each slightly longer than wide; and interstrial rows of erect scales each slightly more than twice as long as ground vestiture and about three times as long as wide.

Female.- Similar to male except frons weakly convex, transversely impressed just above epistoma, minute punctures more evident, lateral margins not elevated or armed; pronotal asperities evident only at anterolateral angles; interstrial granules larger; interstrial bristles often longer, each up to five times as long as wide.

Distribution.- Costa Rica to Venezuela.
COSTA RICA: 4 km NW Cañas, Guanacaste, 13-VIl66, 50 m , Acacia sp., No. 10, S. L. Wood.

Biology. - This species attacks broken branches and twigs less than 2 cm in diameter. The parental tunnels are in the cambium region.

Notes.- The above treatment was based on the type series of 82 specimens.

## 37. Chramesus disparilis Wood

Chramesus disparilis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):9 (Holotype, male; Lagos de Colores, Chiapas, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species superficially resembles acacicolens Wood, but the male frons is entirely different; the elytral ground vestiture and erect bristles are broad. It is not
closely related to any species from North or Central America.

Male.- Length $1.4-1.7 \mathrm{~mm}, 1.9$ times as long as wide; color dark brown, vestiture pale.

Frons very deeply, broadly concave from epistoma to slightly above eyes; lateral margins subacutely elevated, armed just above level of antennal insertion by a pair of low, blunt, subquadrate denticles having their bases displaced mesad from crest of lateral margins; surface finely rugose-reticulate, shining; vestiture of sparse, minute hair in concavity, a few stout setae of moderate length at margins. Antennal club small for this genus, apex narrowly rounded.

Pronotum 0.76 times as long as wide; widest at base, sides and anterior margin almost forming a semicircular arc, anterior constriction almost obsolete; surface finely reticulate, shining, small granules of moderate abundance extending from anterior margin to base. Vestiture rather abundant, short, scalelike, each scale about two to three times as long as wide.

Elytra 1.3 times as long as wide; sides almost straight and parallel on slightly more
than basal half, rather broadly rounded behind; basal margins each armed by 13 crenulations, about 6 submarginal crenulations scattered from interstriae 2-4; striae distinctly, weakly impressed, punctures rather coarse, deep; interstriae slightly wider than striae, each with a uniseriate row of fine granules and minute, obscure punctures. Declivity rather steep, convex; as on disc except interstriae 2 on lower half devoid of granules and feebly impressed. Vestiture consisting of ground cover of short, recumbent, interstrial scales, each scale about twice as long as wide; and interstrial rows of erect, scalelike bristles, each about six times as long as wide, each slightly more than half as long as distance between rows or between bristles within a row.

Female. - Similar to male except frons feebly convex, lateral margins rounded and unarmed; scales in elytral ground cover only slightly longer than wide.

Distribution.- Chiapas.
MExICO: Chiapas: Layos de Colores, If-VI-69, Acacia, D. E. Bright.

Notes.- The above treatment was based on the type series of 49 specimens.

## Tribe HYPOBORINI

Hypoborinae Nüsslin, 1911, Zeitschr. wissensch. Insektenbiol. 7:376 (Type-genus: Hypoborus Erichson, 1836)

Anatomical features.- The frons of some American Liparthrum species is sexually dimorphic, with the male frons flat to convex, the female impressed; most species are not dimorphic; in the remainder of the tribe the male frons is impressed, the female flat to convex. In addition, the eye is entire, the antennal funicle is $4-5$-segmented, the pronotum usually is armed, the procoxae are contiguous, the third tarsal segments are slender, the scutellum is not visible, the elytral crenulations do not extend laterad from striae 5 , and the metatergum is fused to the postnotum.

Biological features.- All species are monogamous and phloeophagous. Parental tunnels in Liparthrum are a simple cave or enlarged nuptial chamber, with the eggs placed in niches along the margin. In Chaetophloeus short, crude egg galleries may extend from the central chamber, with the eggs placed in obscure niches. Larval mines wander considerably, but rarely cross one another. Symbiotic relationships with fungi have not been reported.

Taxonomy.-Liparthrum is apparently a relic genus with a few rare species scattered almost worldwide except Australia. Chaetophloeus is largely restricted to southwestern North America, with two species in South America. Allied genera occur in Africa. Members of this tribe apparently prefer arid or semiarid areas and tend to be rather rare. The two American genera are very different and easily distinguished from one another.

## Genus ChaEtophloeus LeConte

Chatophloeus LeConte, 1876, Proc. Amer. Philos. Soc. 15:382 (Type-species: Hylesinus hystrix LeConte, monobasic)
Renocis Casey, 1886, California Acad. Sci. Bull. 6:257 (Type-species: Renocis heterodoxus Casey, monobasic); Schedt, 1963, Ent. Abh. Ber. Mus. Tierk. Dresden 28:363. Synonymy

Pseudocryphalus Swaine, 1917, Dom. Canada Dept.
Agric. Ent. Br. Tech. Bull. 14(1):20 (Type-species:
Psendoeryphalus brittaini Swaine, original designation); Blackman, 1940, Proc. U.S. Nat. Mus. 88:374. Synonymy
Diagnosis.- In the American fauna this genus is most nearly related to Liparthrum. It is distinguished from Liparthrum by the larger size, by the 5 -segmented antennal funicle, by the reduced, different pronotal armature, and by other characters.

Description.- Length $1.1-2.5 \mathrm{~mm}$, 1.4-2.1 times as long as wide; color brown to black. Frons dimorphic, males transversely impressed to deeply, rather broadly concave, females convex to transversely impressed; epistomal brush very conspicuous; eye elongate, sinuate to feebly emarginate; about 3.5 times as long as wide. Antennal scape moderately short, not reaching posterior margin of eye; funicle 5 -segmented; club slender to subcircular, usually marked by three, aseptate, transverse sutures. Pronotum wider than long, armed by two or three paired groups of asperities in anterolateral areas. Scutellum absent. Elytral bases armed between suture and striae 4 by coarse crenulations, submarginal crenulations present or absent; striate. Third tarsal segments slender. Vestiture of plumose to scalelike setae, often in various patterns of dark and light colors.

Distribution.- Canada to Brazil. Nineteen species are known, 15 are from North and Central America, 2 are from South America, and 2 are from Jamaica.

Brology.- All species attack branches and twigs of trees and shrubs, particularly in desert areas. They are monogamous; the male constructs the entrance tunnel and a large nuptial chamber in the cambium region; the female constructs from one to three rather short, broad, egg galleries. The eggs are deposited in obscure, contiguous egg niches at the ends of the egg galleries. The larval mines usually radiate out individually from
the apical half of the egg gallery, usually curving so as to parallel the grain of wood by the later stages of growth. Larval mines are comparatively long and form a definite pattern; they engrave both the phloem and the
wood, usually engraving the latter rather deeply in the later stages. Evidently two or more generations can be completed annually.

Notes.-All 19 species were included in the key, although four are extratentorial.

## Key to the Species of Chactophlocus

1. Elytral bases armed by 6 to 8 pairs of marginal crenulations ( 5 pairs in occasional maclayi), usually in a continuous marginal line, crenulations 2 and 3 not more widely separated than others, 2 not displaced posteriorly; 1 or 2 pairs of submarginal crenulations often present on interstriae 1 or 2

- Elytral bases armed by 3 to 5 pairs of marginal crenulations, 1 and 2 partly or completely fused, lateral margin or all of 2 strongly displaced posteriorly forming with 1 a median crescent-shaped elevation, a conspicuous gap between 2 and 3 at least as wide as 3; submarginal crenulations never present
2(1). Pronotal and elytral setae all long, subplumose, each apically hairlike or at least very strongly acuminate, those on interstriae at least as long as width of an interstriae; antennal suture 3 at middle of club; female frons armed by a pair of tubercles; larger species; in Rhus
- Pronotal and elytral setae at least partly scalelike, longer setae never 3(2). Elytral declivity strongly sulcate, lateral convexities bearing a series of coarse teeth on interstriae 3; pronotal punctures moderately coarse, deep; $S$ California to Baja California; Rhus; 1.9-2.5 mm ........................ 1. hystrix (LeConte)
- Elytral declivity strongly, shallowly sulcate, all interstriae devoid of granules or teeth; pronotal punctures smaller, rather shallow; Oaxaca to Chiapas; Rhus; $1.8-2.5 \mathrm{~mm}$

2. lasius Wood

4(2). Male frons abruptly impressed immediately above epistoma, impression not attaining upper level of eyes, bearing in female (usually in both sexes) a pair of small, widely separated denticles on upper half; elytral declivity shallowly to rather strongly sulcate; submarginal crenulations on elytral bases absent (except sulcatus)

5(4). Elytral ground cover of sharply acuminate, subplumose, subscalelike setae; all setae on pronotum and elytra white; S California to Arizona; Encelia farinosa; $1.8-2.2 \mathrm{~mm}$

- $\quad$ Scales of elytral ground cover blunt, not at all plumose; dark and light setae variously distributed on pronotum and elytra
6(5). Erect, elongate scales absent on declivital interstriae 1 and 2; pronotal and elytral scales in a distinctive color pattern, white predominating, pronotum with
conspicuous dark patches conspicuous dark patches at center and in anterolateral areas; $S$
California; Encelia californica; California; Encelia californica; 1.7-1.9 m
- Rows of erect, elongate scales on declivital interstriae 1 and 2 as on other................................ interstriae; dark and light setae intermixed on pronotum and elytra except all
white on interstriae 1 (except sulcatus) ...................................................................

7(6). Submarginal crenulations on elytral bases entirely absent; declivital sulcus poorly developed; pronotum and elytra without distinct patches of white scales except interstriae 1; erect interstrial scales at least four times as long as wide; British Columbia and Manitoba to California and W Texas; Prunus, Cercocarpus, etc.; $1.6-2.2 \mathrm{~mm}$

5. heterodoxus (Casey)

- One pair of small submarginal crenulations present at base of interstriae 2; declivital interstriae 2 more strongly impressed, 3 weakly but distinctly elevated at least apically; small patches of light scales irregularly scattered on pronotum and elytra; erect interstrial scales less than three times as long as wide; Hidalgo; Rhus?; $1.6-2.0 \mathrm{~mm}$
.. 6. sulcatus (Wood)
8(4). Male frons shallowly excavated, longest ornamental setae less than half length of excavated area; female epistomal margin straight (except weakly emarginate in brasiliensis); smaller, less than 1.6 mm ; body more slender, at least 1.7 times as long as wide
- Male frons deeply excavated, upper margin of excavation ornamented by very long hair, some of it attaining epistomal margin; epistoma of both sexes broadly emarginate; larger than 1.6 mm ; body stout, less than 1.6 times as long as wide; in mistletoe
$9(8)$. Base of elytra on interstriae 1 and 2 with one or two pairs of submarginal crenulations
Submarginal crenulations entirely absent from bases of elytra, only marginal crenulations represented
$10(9)$. Erect elytral scales and pronotal scales each three or more times as long as wide; male epistomal margin very deeply, broadly emarginate; male frons shallowly impressed, impression extending only slightly above upper level of eyes; declivital striae not at all impressed, punctures small, deep; Yucatán; 1.8 mm ... 7. coronatus (Chapuis)
- Erect interstrial scales and some pronotal scales each less than twice as long as wide; male epistomal margin straight or weakly emarginate (brasiliensis); male frons more deeply, more extensively impressed; declivital striae 1 at least weakly impressed
$11(10)$. Setae on pronotum and elytra forming a color pattern of dark and light scales; male frons more abruptly impressed below, epistomal margin straight; Arizona to Guatemala; Eysenhardtia; 1.2-1.6 mm
- All pronotal and elytral setae pale in color; male frons evenly concave, epistomal margin weakly to shallowly emarginate
12(11). Erect interstrial scales almost twice as long as wide; striae more strongly impressed, punctures toward suture less distinct; Brazil; $1.2-1.4 \mathrm{~mm}$
- Erect interstrial scales almost as wide as long; discal interstriae not impressed, punctures rather deep; Colima; 1.1-1.3 mm

9. minimus Wood

13(9). Strial punctures moderately small, rather deep; interstriae as wide or slightly wider than striae; antennal club large, subcircular, its width 1.5 times greater than length of scape; S Florida, Cuba, Virgin Islands; Acras; 1.3-1.5 mm ..
10. insularis (Blackman)

- $\quad$ Strial punctures coarse, deep; interstriae mostly slightly narrower than striae; antennal club smaller, narrowly oval, its width and length of scape equal; Jamaica; 1.6 mm

14(8). Erect interstrial scales slightly shorter, indistinguishable from setae in ground cover on anterior half of disc; long hair on male vertex yellow, longest setae attain epistoma; female frons more strongly convex, more coarsely granulate; anterior mandibular process pointed, smaller

- Erect interstrial scales longer, distinguishable from setae in ground cover to base; hair on male vertex reddish, longest setae attain tips of mandibles; female frons less strongly convex, more finely granulate; anterior mandibular process pointed or quadrate, larger
15(14). Strial punctures near base of declivity coarse, deep, interstriae less than twice as wide as striae; elytral setae pale; male frons less deeply concave; Jamaica; Phoradendron; $1.8-2.1 \mathrm{~mm}$
- Strial punctures very small, interstriae at least four times as wide as striae; elytral setae with irregular small patches of dark brown setae interspersed among pale setae; male frons more strongly concave; Jalisco to Oaxaca; Phoradendron and Struthanthus; $1.6-2.3 \mathrm{~mm}$........................... 11. struthanthi Wood
16(14). Anterior mandibular process pointed; male epistomal margin bidentate near median line; erect elytral bristles on dise slightly longer, broad, about two to four times as long as wide; Venezuela; Mimosa, etc.; $1.3-1.8 \mathrm{~mm}$
 ed at median line; erect elytral bristles male epistomal margin obtusely pointed at median line; erect elytral bristles on disc shorter, more slender, each four to six times as long as wide; Honduras to Costa Rica; Phoradendron; 1.5-2.0 mm

> 12. phoradendri Wood

17(1). Elytral declivity sulcate; declivital interstriae 3 rather strongly elevated; male frontal excavation more shallow, less extensive; $S$ California to $S$ Arizona; Cercidium; 1.8-2.4 mm . 13. parkinsoniae (Blackman) Elytral declivity convex; declivital interstriae about equally convex; male frontal excavation deeper, more extensive; smaller than 1.8 mm
18(17). Median rows of erect, interstrial setae about twice as long and some at least twice as wide as setae in ground cover; setae unicolorous; anterior fifth of pronotum bearing a pair of small, very long tufts of setae; California and Colorado to Queretaro; Rhus; $1.0-1.5 \mathrm{~mm}$ elytral ground cover; setae dark and light, in a mottled pattern; longest setae on anterior margin of pronotum more generally distributed, increasing in length gradually; S California and Arizona to W Texas and '"Mexico"; Larrea, Prosopis; 1.4-1.8 mm
15. fasciatus (Blackman)

1. Chaetophloeus hystrix (LeConte)

Figs. 101, 102
Hylesinus hystrix LeConte, 1858, Proc. Acad. Sci. Philadelphia 4:81 (Holotype, male; San Diego, California; Mus. Comp. Zool., 1027)
$\mathrm{D}_{\text {Iagnosis. - The large size, the sulcate }}$ elytral declivity with dentate interstriae 3 , and the long, fringed (subplumose) elytral setae distinguish this species from all others in the genus.

Male.- Length $1.8-2.5 \mathrm{~mm}, 1.9$ times as long as wide; color black, vestiture pale.

Frons strongly, broadly, transversely impressed (essentially concave) from epistoma to upper level of eyes; surface almost smooth, with rather fine, moderately close punctures, a pair of rather large, widely separated granules at upper level of eyes; vestiture abundant, very coarse, moderately long, obscuring much of surface, epistomal brush
conspicuous. Antennal club 1.7 times as long as wide; suture 3 obscure, near middle of club; sutures somewhat procurved.

Pronotum 0.74 times as long as wide; basal margin almost straight; widest one-fourth from base, sides strongly arcuate, converging to conspicuous constriction just behind broadly rounded anterior margin; surface smooth, shining, closely, rather coarsely, deeply punctured, with two pairs of groups of asperities in anterolateral areas, one to three asperities in each group; vestiture of rather abundant, moderately long subplumose setae, some bifid setae in marginal areas.

Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; basal margins each armed by six crenulations, increasing in height until very strongly elevated at suture, two or three pairs of submarginal crenulations on interstriae 1 and 2; sides almost

 third strongly, rather gradually elevated, armed at summit by about four coarse teeth, 1 and 2 essentially as on disc except lateral half of 2 ascending toward elevated area. Vestiture rather long, abundant, consisting of tapered subplumose (fringe often of very inconspicuous) setae.

Female.- Similar to male except frontal impression not as deep; antennal club larger, 1.5 times as long as wide; elevation on elytral declivity slightly smaller, usually fewer dentations.

Distribution.-S California to Baja California.

USA: California: Arroyo Seco near Pasadena, Los Angeles N. F., 12-XI-34, A. T. McClay, 18-IV-62, Rhus ${ }_{\text {ocata, }}$ D. E. Bright, B. A. Barr; Peters Canyon, 26-I-32, R. integrifolia, A. T. McClay; San Diego, 17-XII-1890, F. E. Blaisdell, 29-XII-12, R. integrifolia; Aguanga; El Segundo: La Canada; Montrose; Pinyon Flat 16 miles SW Palm Desert, R. laurina. MEXICO: Baja California: 16 km S California border.

Hosts.-Rhus integrifolia, R. ovata, R. laurina.

Biology. - Presumably as described for the genus.

Notes. - The above treatment was based on the holotype and on 71 other specimens.

## 2. Chaetophloeus lasius Wood

Chaetophloeus lasius Wood, 1956, Canadian Ent. 88:251 (Holotype, female; Nochixtlán, Oaxaca, Mexico: Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species is distinguished from hystrix (LeConte) by the more finely, shallowly punctured elytra with strial and interstrial punctures confused, by the absence of declivital armature, and by the longer, more nearly plumose vestiture.

Male.- Length $1.8-2.5 \mathrm{~mm}, 1.9$ times as long as wide; color dark brown to black, vestiture pale brownish.

Frons as in hystrix; antennal club 1.3 times as long as wide, sutures somewhat procurved.

Pronotum 0.72 times as long as wide; as in hystrix except punctures distinctly smaller, anterolateral areas with three pairs of groups of asperities; vestiture slightly longer.

Elytra 1.1 times as long as wide, 1.5 times as long as pronotum; basal armature as in hystrix; sides straight and parallel on slightly more than basal half, broadly, shallowly emarginate behind; strial and interstrial punctures subequal in size, confused, rather small, deep, close (very indistinct striae discernible on some specimens). Declivity steep, broadly sulcate; suture weakly elevated, area of striae 1 impressed, ascending to lateral summit at position of interstriae 3 ; setae in rows where interstriae 1 and 2 normally located. Vestiture consisting of abundant, very long, tapered, subplumose setae, most setae transversely flattened at their bases.
Female.- Similar to male except frons shallowly impressed; antennal club very slightly larger; elytral declivity very slightly less strongly impressed.

Distribution.- Oaxaca to Chiapas.
MEXICO: Chiapas: 32 km NW Comitán 17-VI-64. 2000 m , No. 70s, Rhus, S. L. Woodi: $1+\mathrm{km}$ SE Teopisca on Highway 24, 30-V-69, Rhus, D. E. Bright. Oaxaca: II km SE Nochixtlán, 5 -VII-53, S. L. Wood; 25 miles SE Nochixtlán, 17-VI-67, about $2400 \mathrm{~m}, ~ N o .53$, Bhus, S. L. Wood.

Host.- Rhus sp.
Biology.- Evidently as described above for the genus.
Notes. - The above treatment was based on 53 paratypes and on 266 other specimens.

## 3. Chaetophloeus pruinosus (Blackman)

Figs. I0I, 102
Renocis pruinosus Blacknan. 1940. Proc. U.S. Nat. Mus. 88:383 (Holotype, female; San Bernardino Co., California; U.S. Nat. Mus., 52950).
Diagnosis.- This species is distinguished from maclayi (Bruck) by the slightly larger size, by the more strongly impressed elytral declivity, by the acuminate scales of the elytral ground cover, and by the uniformly white vestiture.

Male.- Length 1.8-2.2 mm, 1.8 times as long as wide; color brown, with white vestiture.

Frons rather strongly, broadly impressed from epistoma almost to upper level of eyes; surface reticulate above, more irregular below, finely punctured; largely obscured by
abundant, coarse, subplumose setae (frontal granules evidently present). Antennal club 2.6 times as long as wide; sutures straight, transverse.

Pronotum 0.62 times as long as wide; widest one-third length from base, sides moderately arcuate and converging very slightly on posterior two-thirds, then rather strongly converging to moderate constriction just before very broadly rounded anterior margin; surface finely, rather deeply, very closely punctured: two pairs of groups of asperities, anterior group with two or three, posterior with four or five dentations; vestiture of small, dense, subacuminate scales, each about two to three times as long as wide, slightly longer on anterior margin.

Elytra 1.1 times as long as wide, 1.9 times as long as pronotum; basal margins each armed by five to seven crenulations as in hystrix; sides almost straight and subparallel on basal two-thirds, broadly rounded behind; striae 1 weakly, others not impressed, punctures rather small, moderately deep; interstriae about twice as wide as striae, minutely granulose, fine punctures confused, median row sometimes minutely granulate. Declivity rather steep, broadly, rather shallowly impressed between third interstriae; sutural interstriae very feebly elevated, remaining sculpture essentially as on disc. Vestiture consisting of ground cover of numerous small, strongly acuminate, semirecumbent scales; and interstrial rows of erect, slightly longer, almost scalelike bristles, each bristle four to six times as long as wide and about two-thirds as long as distance between rows, irregularly but usually more closely spaced within a row.

Female. - Similar to male except frons less strongly impressed, almost flat.
Distribution.-S California to Arizona.
USA: Arizona: Catalina Springs, Encelia farinosa, H. G. Hubbard and E. A. Schwarz. California: Indio, 29-VI33, R. H. Beamer: San Bernardino Co., Coquillet; Pi-
cacho, 23-II-40; "Cal." cacho, 23-II-40; "Cal."

## Host.-Encelia farinosa.

Biology. - The habits have not been recorded, except for the host.

Notes.- The above treatment was based on the holotype and on 14 other specimens.

## 4. Chaetophloeus maclayi (Bruck)

Psendocryphalus maclayi Bruck, 1936, Bull. S. California Acad. Sci. 35:35 (Holotype, female; Westwood Hills, Los Angeles Co., California; Ohio State Univ.)
Diagnosis.- This species is distinguished from pruinosus (Blackman) and heterodoxus (Casey) by the more broadly flattened elytral declivity, by the absence of erect scalelike bristles on declivital interstriae 1 and 2, and by the definite color pattern of dark and light scales.

Male.- Length 1.7-1.9 mm, 1.8 times as long as wide; color dark brown with pale and dark brown scales forming a definite color pattern, pronotum pale with dark oval patches on central third and anterolateral angles, elytra pale with dark transverse bands at base and on upper part of declivity and posterior part of disc, these two bands sometimes connected along interstriae 3 and 5 .

Fig. 102. Chactophloeus spp., protibiae: a, b, parkiusoniae; c, prumosus; d, fasciatus; e, f, g, h, i, heterodoxus; j, penicillatus; k, mexicanus, 1, m, braziliensis; n, insularis; o, hystrix. (After Blackman 1940:381.)

Frons transversely, subconcavely impressed from immediately above epistoma to slightly above upper level of eyes; surface subshining, minutely punctured, largely obscured by rather abundant, coarse, subplumose setae of moderate length; a pair of coarse, widely separated granules at upper level of eyes. Antennal club 2.0 times as long as wide.

Pronotum 0.71 times as long as wide; widest one-third length from base, sides strongly arcuate, converging anteriorly to distinct constriction just before broadly rounded anterior margin; surface rather finely, shallowly, very closely punctured; anterolateral areas armed by two pairs of groups of asperities, each group with two or three dentations; vestiture of small, abundant scales, each bluntly pointed at its apex and two to three times as long as wide, slightly longer on anterior margin.

Elytra 1.1 times as long as wide, 1.6 times as long as pronotum; basal margins armed as in hystrix by six pairs of crenulations, submarginal crenulations absent; striae not impressed, punctures moderately large, rather deep, each wider than long; interstriae as wide as striae, minutely, shallowly punctured, punctures confused. Declivity rather steep, broadly convex, very feebly impressed between third interstriae; evidently as on disc except strial punctures greatly reduced in size. Vestiture of abundant, short, oval scales in interstrial ground cover, each about two to three times as long as wide; and uniseriate interstrial rows of longer erect scales, each erect scale twice as long as ground scales and two to three times as long as wide, about half as long as distance between rows; erect setae absent on declivital interstriae 1 and 2.

Female.-Similar to male except frontal impression reduced, almost flat, frontal vestiture shorter, less abundant.

Distribution.-S California.
USA: California: Westwood Hills, Los Angeles Co., S.11-V-35, 30-X11-35, 9-VII-36, Eneelia californica, A. T. McClay.

Biology. - Not recorded except for the host.

Notes.- The above treatment was based on the holotype and on more than 48 paratypes. A male "holotype" is in the collection of the University of California at Davis. It is obvious from Bruck's description that the
holotype was deposited in his collection, which is now at Ohio State University. The label on the Davis specimen is considered to be a labeling error and the specimen should be regarded as a paratype.

## 5. Chaetophloeus heterodoxus (Casey) Figs. 96, 101-103

Renocis heterodoxus Casey, I886, California Acad. Sci. Bull. 6:258 (Holotype, female: Reno, Nevada; U.S. Nat. Mus., 37489)

Pseudocryphalus hrittaini Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):20 (Lectotype, male; Salmon Arm, British Columbia; Canadian Nat. Coll. desiguated by Bright, 1967, Canadian Ent. 99:679); Wood. 1957, Canadian Ent. 89:402. Synonymy
Pseudocryphalus criddlei Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):21 (Lectotype. male; Aweme, Manitoba; Canadian Nat. Coll., designated by Bright, 1967, Canadian Ent. 99:679); Wood, 1957, Canadian Ent. 89:402. Synonymy
Renocis brunncus Blackman, 1940, Proc. U.S. Nat. Mus. 88:389 (Holotype, female; Cloudcroft, New Mexico; U.S. Nat. Mus., 52952); Wood, 197I, Great Basin Nat. 31:142. Synonymy
Renocis fuscus Blackman, 1940, Proc. U.S. Nat. Mus. 88:391 (Holotype, female; Williams, Arizona; U.S. Nat. Mus., 52953); Wood, 1971, Great Basin Nat. 31:142. Synonymy
Renocis commixtus Blackman, 1940, Proc. U.S. Nat. Mus. 88:392 (Holotype, female; Williams, Arizona; U.S. Nat. Mus., 52594); Wood, 1971, Great Basin Nat. 31:142. Synonymy
Diagnosis.- This is the most abundant, most widely distributed species in the genus. It is not nearly as variable as the above list of synonyms might suggest. It is distinguished from pruinosus (Blackman) and maclayi (Bruck) by the much more slender pronotal and elytral ground cover scales, by the more narrowly convex elytral declivity, and by the different coloration.

Male.- Length 1.6-2.2 mm, 1.9 times as long as wide; color black, with scale color pattern normally white on pronotum and on interstriae 1, dusky to very dark scales elsewhere, with a few pale or dark scales scattered at random, occasional specimens much lighter or much darker.

Frons rather strongly, transversely impressed from epistoma almost to upper level of eyes; surface very finely punctured, largely obscured by abundant, coarse, subplumose setae; a pair of large, widely separated granules at upper level of eyes;
epistomal brush very conspicuous. Antennal club 2.2 times as long as wide.

Pronotum 0.62 times as long as wide; outline and surface sculpture as in maclayi except often a third paired group of lateral asperities may occur on anterior margin, rarely consisting of more than one dentation; vestiture consisting of small slender scales, usually each scale three or more times as long as wide, occasionally a few larger, broader scales intermixed, setae on anterior margin longer.

Elytra 1.2 times as long as wide, 2.1 times as long as pronotum; basal margins and outline about as in maclayi; striae 1 weakly,

Fig. 103. Chaetophloeus heterodoxus, galleries. (After Furniss and Barr 1975:17.)
others not at all impressed, punctures rather small, deep, close; interstriae twice as wide as striae, minutely punctured, punctures close, confused. Declivity steep, rather broadly convex; striae moderately impressed, more strongly on 1, punctures smaller, not as deep. Vestiture of abundant small, semirecumbent scales, each scale about four to six or more times as long as wide (variable on any specimen); and uniseriate interstrial rows of erect scalelike bristles, each more than twice as long as ground scales, about three to six times as long as wide.

Female.-Similar to male except frons much less strongly impressed.

Distribution.- British Columbia and Manitoba to California and W Texas.
CaNADA: British Columbia, Manitoba, Saskatchewan. USA: Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, North Dakota, Oregon, South Dakota, Texas, Utah, Washington, Wyoming.

Hosss.- Amelanchier utahensis, Cercocarpus betulifolia, C. ledifolia, C. parvifolius, Cowania mexicana, Peraphyllum ramosissimum, Prunus americana, P. virginiana, Pyrus malus, Ribes spp.

Habits.- The above generic treatment of habits was based largely on this species.

Notes. - The holotypes or lectotypes of heterodoxus, brittaini, criddlei, brunneus, fuscus, and commixtus were all examined and used in the preparation of the above treatment along with 387 other specimens. The presence of boring dust, body oils, or wear on the surface of specimens of this species can drastically alter their appearance. Its broad distribution and wide host range evidently have also contributed to the description of synonyms.

In the southeastern part of its range the elytral ground scales and erect bristles tend to be very slightly wider and there is a tendency for two rather than three paired groups of pronotal asperities. These appear to be gradual clinal differences, however, and do not warrant a distinct name.

## 6. Chaetophloeus sulcatus (Wood)

Renocis sulcatus Wood, 1956, Canadian Ent. 88:252 (Holotype, female; Ixmiquilpan, Hidalgo, Mexico; Snow Ent. Coll., Univ. Kansas)
Diagnosis. - This species is distinguished from maclayi (Bruck) by the less strongly impressed frons, by the smaller frontal
tubercles, by the more strongly elevated lateral areas of the elytral declivity, by the presence of erect scales on declivital interstriae 1 and 2 , and by the different color pattern.

Male.- Length $1.6-2.0 \mathrm{~mm}, 1.8$ times as long as wide; color dark brown, with very dark and pale scales forming a variegated pattern with dark and light areas about equal.

Frons rather weakly, transversely impressed above epistoma, impression ending below upper level of eyes; surface minutely granulate-punctate above, becoming smooth toward epistoma; a pair of widely separated granules at upper level of eyes; vestiture of rather abundant, moderately short, stout, subplumose setae. Antennal club 2.4 times as long as wide.

Pronotum 0.68 times as long as wide; essentially as maclayi except scales rather broad, with rounded apeces; distinctly longer on anterior margin.

Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; basal margins each armed by six crenulations, median one much larger, higher, one submarginal crenulation; sides almost straight and subparallel on basal two-thirds, broadly subemarginate behind; striae 1 weakly, others not impressed, punctures moderately small, rather deep; interstriae almost twice as wide as striae, punctures very small, shallow, confused. Declivity rather steep, broadly, shallowly sulcate between third interstriae; suture feebly elevated, interstriae 1 moderately impressed on its median side, 3 moderately elevated particularly near its apex; sculpture essentially as on disc. Vestiture of small, abundant, ground scales, each from one to three times as long as wide and narrowly rounded at apex; and uniseriate interstrial rows of erect scales, each scale about twice as long as ground scales and twice as long as wide, those on declivital interstriae 1 smaller, those on 2 small and less abundant.

Female.- Similar to male except frons very weakly impressed, almost flat below upper level of eyes.

Distribution.- Hidalgo.
MEXICO: Hidalgo: Ixmiquilpan, 23-VI-53, S. L. Wood.

Biology. - Similar to those described for the genus. The unidentified host was a shrub having a growth habit much like Condalia.

Notes.- The above treatment was based on 11 paratypes.

## 7. Chaetophloeus coronatus (Chapuis)

> Phloeosinus coronatus Chapuis, 1869, Synopsis des Scolytides, p. 39 (Holotype, male; Yucatán, Mexico: Brussels Mus.)

Diagnosis. - This species apparently is more closely allied to brasiliensis (Blackman) than to other known species, but it is distinguished by the more slender body, by the very deeply, broadly emarginate epistomal margin of the male, with the frontal impression less extensive and shallow, by the less strongly impressed striae, and by the very different elytral vestiture.

Male.- Length $1.8 \mathrm{~mm}, 1.9$ times as long as wide; rather dark brown, elytra lighter, all setae pale, almost white.

Frons shallowly concave from epistomal margin to very slightly above upper level of eyes; epistomal margin slightly elevated, deeply emarginate on a broad arc one-fourth as deep as wide; upper two-thirds of frons rather coarsely granulate; marginal fringe of subplumose setae longer above, longest setae about equal to half length of frons. Both antennae missing from type except left club loosely clinging to normai position, club 2.1 times as long as wide; three sutures mark approximately equal fourths.

Pronotum 0.70 times as long as wide; basal margin somewhat bisinuate, sides widest on basal third, strongly, arcuately convergent on posterior two-thirds, moderately constricted just before rather broadly rounded anterior margin; lateral areas armed by two pairs of groups of asperities; surface minutely subgranulose, with fine punctures; vestiture scalelike, each about two to four times as long as wide, longer at posteromedian margin.

Elytra 1.5 times as long as wide, 2.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; basal margins each armed by six crenulations at bases of interstriae 1 to 4, one submarginal crenulation on 1 ; striae not at all impressed, punctures rather small, moderately deep; interstriae about twice as wide as striae, subshining, punctures fine,
confused, rather close. Declivity convex, moderately steep; as on disc; striae not at all impressed. Vestiture consisting of white scales, each three to four times as long as wide, median row on each interstriae slightly longer and identifiable only toward declivity.

Distribution.- Yucatán.
MEXICO: "Yucatán, Deyr."
Notes. - The above treatment was prepared directly from the male holotype.

## 8. Chaetophloeus mexicanus (Blackman)

 Figs. 101, 102Renocis mexicanus Blackman, 1940, Proc. U.S. Nat.
Mus. 88:397 (Holotype, female; Guadalajara, Jalisco, Mexico; U.S. Nat. Mus., 52955)
Renocis mexicanus Eggers, 1951 (nec. Blackman, 1940), Ent. Blätt. 45-46:149 (Holotype. evidently a male; Mexico; Schedl Coll.); Wood, 1971, Great Basin Nat. 31:142. Synonymy
Renocis cagersi Wood, 1956, Canadian Ent. 58:253 (Replacement name)
Renocis blackmani Nunberg, 1956, Ann. Zool. (Wařaw) 16:208 (Replacement name)
Diagnosis.- This species is distinguished from minimus Wood by the larger average size, by the stouter, more abundant scales in the elytral ground cover, by the more abundant, more generally distributed frontal vestiture, by the less extensively excavated male frons, and by the color pattern.

Male.- Length 1.2-1.6 mm, 1.9 times as long as wide; color very dark brown, scales dark brown except pale band across base and usually sides of pronotum, sides of elytral disc mostly pale laterad from interstriae 4 with some pale scales on disc between interstriae 4 (pattern variable).
Frons moderately concave from epistomal margin to well above eyes; surface finely punctate-granulate; vestiture of abundant, coarse, moderately long, subplumose setae, particularly concentrated on margins. Club 2.3 times as long as wide; all sutures indicated only at margins.

Pronotum 0.65 times as long as wide; outline and surface structure essentially as in maclayi except groups of small granules instead of asperities in anterolateral areas; vestiture of a mixture of short, subcircular scales and equally long, slender, recumbent setae, slightly longer on anterior margin.

Elytra 1.2 times as long as wide, 1.9 times as long as pronotum; basal margins each armed by 6 to 8 crenulations, increasing in height toward suture, and two rather coarse submarginal crenulations, one each at bases of interstriae 1 and 2 ; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae feebly if at all impressed, punctures moderately large, rather deep; interstriae slightly less than twice as wide as striae, punctures close, confused, very fine, shallow. Declivity steep, convex; striae 1 more distinctly impressed; sculpture essentially as on disc. Vestiture consisting of abundant, interstrial ground scales, each scale three to four times as long as wide; and uniseriate rows of erect interstrial scales, each scale only slightly longer than ground scales, slightly longer than wide.

Female.-Similar to male except frons convex, a feeble impression above epistoma; two groups of anterolateral crenulations present.

Distribution.- Arizona to Guatemala.
USA: Arizona: Phoenix, 16-XII-40, C. D. Lebert. Mexico: Jalisco, Michoacán, Nuevo León, Oaxaca, Tamaulipas. GUATEMALA: Volcán Pacaya, 1-VI-64, 1300 m, No. 686, S. L. Wood.

## Hosts.- Eysenhardtia spp.

Brology.- As described for the genus.
Notes.- The above treatment was based on the holotypes of mexicanus Blackman and mexicanus Eggers and on 587 other specimens.

The holotype of Eggers species is badly abraded and in rather poor condition; however, the unique submarginal crenulations at the elytral bases, coupled with other characters, leave no doubt concerning the synonymy with Blackman's species.

## 9. Chaetophloens minimus Wood

Chaetophloeus minimus Wood. 1967, Great Basin Nat. 27:95 (Holotype, male; Armeria, Colima, Mexico; Wood Coll.)
Diagnosis.- The small size and vestiture of this species are more nearly like Liparthrum than other species in this genus, but the antennal and other characters clearly
place it in Chaetophloeus. It is distinguished from mexicanus (Blackman) by the smaller size, by the more slender form, by the less strongly impressed striae, by the vestiture, and by the less strongly impressed male frons. Its much closer relationship to braziliensis (Blackman) is treated above under that name.

Male.- Length $1.1-1.3 \mathrm{~mm}, 1.9$ times as long as wide; color almost black, with white vestiture.

Frons rather shallowly concave from eye to eye and from epistoma to vertex; surface reticulate-granulate, vestiture consisting of moderately long, coarse hair, more abundant and longer at sides and above. Antennal club large, 1.8 times as long as wide; three sutures indicated.

Pronotum 0.60 times as long as wide; widest one-fourth of pronotum length from base, sides strongly arcuate on basal half, rather weakly constricted just behind anterior margin; surface subreticulate-granulate, with moderately large, obscure punctures; lateral area armed by one paired group of minute asperities; vestiture consisting of short, stout, hairlike bristles and equally abundant, erect scales, each scale as wide as long.

Elytra 1.3 times as long as wide, 2.0 times as long as pronotum; basal crenulations as in mexicanus, with two pairs of submarginal ones, one each on interstriae 1 and 2; striae not impressed, punctures moderately large, deep; interstriae feebly convex, as wide as striae, punctures fine, confused. Declivity steep; convex; striae and interstriae somewhat narrower than on disc, interstrial punctures evidently subgranulate. Vestiture consisting of short, slender interstrial bristles along both margins of each interstriae, each about four times as long as wide; and median, interstrial rows of erect round scales; scales separated within a row by distances equal to length of a scale, and between rows by distances equal to twice length of a scale.

Female.-Similar to male except frons weakly convex, minutely granulate, vestiture short, sparse; pronotum armed by two pairs of groups of asperities.

Distribution.-Colima.
MESICO: Colima: 3 km E Armeria, 28-VI-65, 70 m , No. 128, S. L. Wood.

Biology.- The small branches of a dead shrub 2 to 3 m tall, from which specimens of this species were removed, were riddled by galleries typical of this genus. The host had a growth habit much like Amelanchier.

Notes.- The above treatment was based on the type series of 17 specimens.

## 10. Chaetophloeus insularis (Blackman) <br> Figs. 101, 102

Renocis insularis Blackman, 1940, Proc. U.S. Nat. Mus. 88:400 (Holotype, female; Key West, Florida: U.S. Nat. Mus., 52957)

Diagnosis.- This species is distinguished from the closely related chapini (Blackman) by the much smaller strial punctures and wider interstriae, by the larger, broad antennal club with procurved sutures, and by the distribution.

Male.- Length 1.3-1.5 mm, 1.7 times as long as wide; color almost black, with pale vestiture.

Frons rather deeply concave from eye to eye from epistoma to vertex; surface finely punctate-granulate; vestiture of rather long, moderately fine, subplumose hair of moderate abundance, longer and more concentrated on margins above. Antennal club 1.3 times as long as wide, sutures moderately procurved.

Pronotum 0.63 times as long as wide; widest one-third pronotum length from base, sides on posterior two-thirds very strongly arcuate, converging to feeble constriction just before broadly rounded anterior margin; surface obscurely subreticulate, punctures moderately coarse, very close, rather shallow; one paired group of lateral asperities; vestiture short, abundant, consisting of slender and stout bristles, stout setae about four times as long as wide.

Elytra 1.1 times as long as wide, 1.9 times as long as pronotum; basal margins each armed by seven crenulations, progressively larger toward suture. No submarginal crenulations; outline as in mexicanus; striae 1 weakly, others not impressed, punctures rather coarse, shallow; interstriae as wide or slightly wider than striae, punctures fine, shallow, close, confused. Declivity steep, convex; essentially as on disc except striae more distinctly impressed, punctures somewhat
smaller. Vestiture consisting of small, abundant, interstrial scales, each scale one to three times as long as wide; and uniseriate, interstrial rows of erect scales, each slightly longer than ground setae and slightly longer than wide.

Female.- Similar to male except frons convex, finely granulate, vestiture short, stout, less abundant; lateral areas of pronotum with two pairs of groups of asperities.

Distribution.-S Florida, Cuba, and the Virgin Islands.
USA: Florida: Matacumba Key, 28-VI-51, Acras sapota, S. L. Wood; Lower Matacumba Key, 29-V1-51, Acras sapota. S. L. Wood: Key West, H. G. Hubbard and E. A. Schwarz; Sugarloaf Kiey, 9-V-67, D. E. Bright. CUBA: Cayamas, H. G. Hubbard and E. A. Schwarz.

Host.- Acras sapota.
Biology. - This species attacked small broken branches of the host. The gallery systems were similar to those described for the genus.

Notes. - The above treatment was based on the holotype, allotype, two paratypes, and on 92 other specimens.

## 11. Chaetophloeus struthanthi Wood

Chaetophloeus struthanthi Wood, 1967, Great Basin Nat. 27:96 (Holotype, male; Volcán de Colima, Jalisco, Mexico; Wood Coll.)
Diagnosis. - This species is closely related to phoradendri Wood, but it is distinguished by the shorter, erect, elytral scales, by the more strongly convex, granulate, female frons, by the shorter, yellow pubescence on the upper part of the male frons, and by the smaller, pointed, mandibular processes in both sexes.

Male.-Length $1.6-1.9 \mathrm{~mm}, 1.6$ times as long as wide; color very dark brown.

Frons rather deeply concave from eye to eye from vertex to broadly emarginate epistomal margin; surface reticulate, with rather close, fine, shallow, subgranulate punctures; vestiture largely confined to marginal areas, longer on upper margin, longest hairs not reaching epistoma, yellow. Antennal club 2.1 times as long as wide; sutures very obscure.

Pronotum 0.60 times as long as wide; widest one-fourth of pronotum length from base, sides very strongly arcuate on basal half, moderately constricted just behind broadly rounded, subemarginate, anterior margin; surface subrugose, rather finely,
closely punctured, lateral areas armed by three pairs of groups of asperities; vestiture consisting of short, slender, erect scales, about eight much longer ones in median basal area, setae along anterior margin slightly longer.

Elytra 1.1 times as long as wide, 2.1 times as long as pronotum; outlines and basal asperities as in phoradendri; basal margins each armed by seven crenulations, progressively larger and higher toward suture; striae weakly impressed, punctures very sinall, shallowly, distinctly impressed; interstriae convex, two or more times as wide as striae, setiferous punctures small, very close, confused. Declivity convex, steep; striae and interstriae narrower and less clearly marked than on disc. Vestiture consisting of short, semierect, small, slender scales of equal length on disc, median row on each declivital interstriae slightly longer.

Female.- Similar to male except frons convex above, flattened below, more nearly granulate; mandibular process smaller; antennal club 1.7 times as long as wide.

Distribution.- Jalisco to Oaxaca.
MEXICO: Jalisco: Volcán de Colima, 23-V1-65. 2500) m, No. 105, Struthanthus probably venetus, S. L. Wood. Oaxaca: 17 km N Huajuapan, 15 -VI-67, No. 43, Phoradendron. S. L. Wood: 19 km S Matías Romero, 24-VI-67. No. 93, Phoradendron, S. L. Wood. Puebla: 13 km W Texmelucan, 13-VI-67, 2600 m , No. 26, Phoradendron, S. L. Wood.

Hosts.-Phoradendron spp., Struthanthus prob. venetus.

Biology.- This monogamous species attacks the larger stems of unthrifty or dying mistletoe. The parental galleries cut much more deeply into the wood than usual for the genus, and evidently are shorter and with fewer egg galleries than in other species. Larval mines are fewer in number, are shorter, and wander more than in other species.

Notes. - The above treatment was based on the type series of 88 specimens and on 20 other specimens.

## 12. Chaetophloeus phoradendri Wood

Chaetophloens phoradendri Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):8 (Holotype, male; Zamorano, Morazán, Honduras; Wood Coll.); Wood, 1969. Great Basin Nat. 29:122 (corrected spelling)

Diagnosis.- This species has the same arrangement of crenulations at the base of the elytra as braziliensis (Blackman), but it differs by the much larger size, by the reduction of elytral striae, by the very different vestiture, and by other characters.

Male.- Length $1.5-2.0 \mathrm{~mm}, 1.4$ times as long as wide; color black, vestiture cinereus.

Frons broadly, deeply concave from vertex to broadly emarginate epistomal margin, from eye to eye; surface minutely granulosereticulate; vestiture sparse in concavity, a few erect gray setae along sides below eye, margin above eyes ornamented by a row of very long, reddish hair, tips of which reach mandibles; mandibles each with an anterior quadrate extension a third as large as mandible. Antennal club 1.9 times as long as wide; two sutures indicated.

Pronotum 0.57 times as long as wide; widest at base, strongly arcuate, converging slightly to very broadly rounded anterior margin; surface reticulate, with very small, rather close, setiferous punctures; lateral areas armed by two groups of asperities; vestiture consisting of mixed slender and stout, short bristles and a few bifid hairs in lateral areas, slightly longer on anterior margin, about eight longer setae in posteromedian area.

Elytra 1.1 times as long as wide, 1.8 times as long as pronotum; anterior margins each armed by six crenulations, median one twice as wide as others, an additional submarginal pair at base of interstriae 1; striae reduced, obscure, punctures only slightly larger than those of interstriae; interstriae wide, flattened, with numerous, confused punctures variable in size. Declivity steep, convex. Vestiture consisting of short, rather abundant, slender scales, and median rows of erect interstrial scales (distinct to base), each scale about three times as long as wide, separated from other scales in same row by distances equal to length of a scale and between rows by one and one-half times length of a scale.

Female.- Similar to male except frons flattened, with a small median impression, frontal vestiture short, not specialized; pronotum armed by three pairs of groups of asperities.

Distribution.- Honduras to Costa Rica.

HONDURAS: Zamorano, Morazán, 18-VI-64, 700 m , No. 569, Phoradendron robustissimum, S. L. Wood. COSTA RICA: 6 km W Cañas. Guancacaste, 10-VI-66. 50 m , No. I, Phoradendron, S. L. Wood: 20 km SE Liberia, Guanacaste, I0-VII-66, No. 16, Fhoradendron. S. L. Wood.

Hosts.- Phoradendron robustissimum, $P$. sp.

Biology.-As in struthanthi.
Notes. - The above treatment was based on the type series of 45 specimens.

## 13. Chaetophloeus parkinsoniae (Blackman)

 Figs. 101. 102Renocis parkinsoniae Blackman, 1940, Proc. U.S. Nat. Mus. 88:378 (Holotype, female; Catalina Springs. Arizona; U.S. Nat. Mus., 52949)
Diagnosis.- In this and the following two species, the crenulations on the basal margins of the elytra are reduced in number, and the sutural crenulation is unusually broad and laterally curved away from the margin, leaving a distinct gap between the first and second crenulations; submarginal crenulations are always absent. This species is distinguished from fasciatus (Blackman) and penicillatus (Bruck) by the larger size, by the sulcate elytral declivity, with interstriae 3 rather strongly elevated, and by the very long, slender, erect, interstrial bristles.

Male.- Length $1.8-2.4 \mathrm{~mm}, 1.6$ times as long as wide; color dark brown, vestiture with pale and dark setae intermixed.

Frons broadly, very shallowly, concavely impressed from epistoma to above upper level of eyes, shining, very finely punctured; vestiture rather abundant on margins, of moderately long, fine, subplumose hair. Antennal club 3.3 times as long as wide, three straight, transverse sutures.
Pronotum 0.62 times as long as wide; widest one-third pronotum length from base, sides on basal two-thirds very strongly arcuate, strongly converging on anterior third, distinctly constricted just before broadly submarginate anterior margin; surface densely, finely, shallowly punctured; three paired groups of asperities on lateral areas; vestiture of short, abundant, erect scalelike bristles of two widths, some two, some four times as long as wide, setae on anterior margin four or more times longer than scales.
Elytra 1.2 times as long as wide, 2.0 times as long as pronotum; sides almost straight and
parallel on slightly less than basal two-thirds, broadly rounded behind except profile interrupted by elevated interstriae 3; basal margins each armed by three crenulations, median one apparently double, much enlarged in width and height, its lateral half curved posteriorly, leaving a distinct gap between it and second crenulation; submarginal crenulations absent; striae rather weakly impressed, punctures moderately small, deep; interstriae almost twice as wide as striae, minutely rugulose, punctures fine, shallow, close, confused. Declivity steep, rather deeply, narrowly sulcate; strongly impressed between interstriae 3,1 and 2 slightly narrowed, 3 rather strongly, abruptly elevated, elevation ending before apex. Vestiture consisting of rather abundant, short ground scales, each scale slightly longer than wide; and uniseriate, interstrial rows of erect bristles, each bristle about three times as long as ground scales, almost as long as distance between rows on declivity, slightly shorter on disc, more closely spaced within a row.
Female.- Similar to male except frons less strongly, less extensively impressed.
Distribution.- S California to $S$ Arizona. USA: Arizona: Catalina Springs, I4-IV-1898, H. G. Hubbard, E. A. Schwarz; Gila Mits., 8-VIII-36, J. N. Knull; Hot Springs, 27-VI, H. G. Hubbard, E. A. Schwarz: Sabino Canyon, Santa Cataiina Mts., Parkinsonia microphylla, G. Hofer. California: Los Angeles. 14-III-41.

## Host.- Cercidium microphyllum.

Biology.- Essentially as described for the genus.
Notes. - The above treatment was based on the holotype and on 103 other specimens.

## 14. Chaetophloeus penicillatus (Bruck) <br> Figs. 101, 102

Renocis penicillatus Bruck, 1933. Canadian Ent. 65:2:39 (Holotype, male; Peter's Canyon, Orange Co., California; California Acad. Sci.)
Diagnosis.- This species is distinguished from fasciatus (Blackman) by the smaller size, by the more conspicuous erect, interstrial setae, by the long, slender tufts of setae on the anterior margin of the pronotum, and by the much more extensively concave male frons.
Male. - Length $1.1-1.5 \mathrm{~mm}, 1.6$ times as long as wide; color almost black, vestiture pale to medium brown, unicolorous except usually lighter on sutural striae.

Frons broadly, rather deeply concave from eye to eye from epistoma to well above eyes; surface reticulate-granulate, almost smooth toward epistoma; vestiture short and sparse in concavity, very long, abundant on lateral margins. Antennal club 1.6 times as long as wide; three sutures indicated.

Pronotum 0.60 times as long as wide; outline and general sculpture as in fasciatus except vestiture of slender and stout, short, abundant setae, stout scales slightly longer than wide, slender ones about four times as long as wide; anterior margin bearing a pair of very long tufts of yellow, subplumose setae, usually fewer than a dozen setae in each tuft.

Elytra 1.2 times as long as wide, 2.0 times as long as pronotum; general outline and armature of basal margins as in fasciatus; striae weakly impressed, punctures rather small, deep; interstriae slightly less than twice as wide as striae, weakly convex, surface marked by numerous minute points, punctures small, close, shallow, confused. Declivity steep, convex; striae more distinctly impressed, sculpture about as on declivity. Vestiture of rather abundant, short scales in ground cover, each scale about twice as long as wide; and uniseriate rows of erect scales, each scale about three times as long as ground scales, two to three times as long as wide, length about half as great as distance between rows, similarly spaced within a row.

Female.- Similar to male except frons convex and a slight, transverse impression just above epistoma, frontal vestiture of uniform length and distribution; pronotum with three paired groups of asperities, tufts of hair on anterior margin usually smaller, scalelike setae more elongate.

Distribution.- California and Colorado to Queretaro and San Luis Potosí.

USA: Arizona, California, Colorado, Nevada, New Mexico, Utah. MEXICO: Queretaro: 16 km or 10 miles E Landa de Matamoros, 11-V1-71, 1500 m, Rhus, D. E. Bright. San Luis Potosí: 48 km or 30 miles E San Luis Potosí, 12-VI-71, D. E. Bright.

Hosts.- Rhus integrifolia, R. microphylla, R. ovata, R. trilobata, R. sp.

Biology.- Essentially as described for the genus.

Notes. - The above treatment was based on 18 paratypes and on 282 other specimens.
15. Chaetophloeus fasciatus (Blackman)

Figs. 101, 102

Renocis fasciatus Blackman, 1940, Proc. U.S. Nat. Mus. 88:385 (Holotype, female; Tucson, Arizona: U.S. Nat. Mus., 52951)
Diagnosis. - This species is somewhat allied to parkinsoniae (Blackman) and penicillatus (Bruck), but it is distinguished by the intermediate size, by the almost indistinguishable erect, interstrial scales, by the deeply, narrowly excavated frons, and by the distinctive color pattern.

Male.- Length $1.4-1.8 \mathrm{~mm}, 1.7$ times as long as wide; color dark, almost black, vestiture of very dark and white setae, dark on sides and basal fourth of pronotum, on elytral declivity except interstriae 1, and on basal third of elytral disc between fifth striae.

Frons deeply concave on about median two-thirds from epistoma to slightly above upper level of eyes; surface finely punctategranulate; vestiture of rather abundant, moderately long, coarse, subplumose setae. Antennal club 2.7 times as long as wide; three straight, transverse sutures.

Pronotum 0.60 times as long as wide; widest one-third pronotum length from base, strongly arcuate and converging to distinct constriction just before very broadly rounded anterior margin; surface smooth, punctures close, shallow, rather fine; lateral areas with two pairs of groups of asperities; vestiture of abundant, short, scales, each scale about two to three times as long as wide except much longer and more slender on anterior margin.

Elytra 1.2 times as long as wide, 2.0 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind; basal margins as in parkinsoniae except median pair bent somewhat posteriorly; striae feebly impressed, punctures small, moderately deep; interstriae twice as wide as striae, punctures small, shallow, close, confused. Declivity steep, convex; interstriae 1 and 3 weakly elevated, 2 slightly impressed, sculpture about as on disc. Vestiture of abundant, short ground scales, each scale about three times as long as wide, rather narrowly rounded at its apex; and uniseriate rows of erect interstrial scales little if any longer than ground setae, usually clearly discernible only on declivity.

Female.- Similar to male except frons moderately, transversely impressed, frontal vestiture evidently shorter.

Distribution.-S California and $S$ Arizona to W Texas and "Mexico."

USA: Arizona: Benson, mesquite, Chissman; 24 km W Douglas, 15-VIII-58, mesquite, J. H. Russell; Patagonia, 20-V-68, Prosopis, D. D. Lucht; Portal, Larrea tridentata; Redington, 10-IV-I3, Prosopis juliflora, M1. Chrisman: Tucson, 14-1V, greasewood, Hubbard and Schwarz, and 17-II-08, mesquite, M. Chrisman. California: Fish Springs, lmperial Co., 1-1-39, mesquite, A. T. McClay. Texas: Presidio, 14-VIl-41, mesquite. MEXICO: Intercepted at U.S. border, 10-XII-48, mesquite, J. M. Russell.

## Genus Liparthrum Wollaston

Leiparthrum Wollaston, 1854, Insecta Maderensia, p. 294 (Type species: Lciparthrum bituberculatum Wollaston, original designation)
Liparthrum Wollaston, 1864, Catalogue of the Coleopterous Insects of the Canaries in the collection of the British Museum, p. 265 (valid emendation, Internat. Comm. Zool. Nomencl. I98I:64)
Erineosinus Blackman, 1920. Mississippi Agric. Expt. Sta. Tech. Bull. 9:53 (Type-species: Erineosinus squamosus Blackman, monobasic); Wood, 1957, Canadian Ent. 89:399. Synonymy
Phloeochilus Schedl. 1953, Ann. Mag. Nat. Hist. (12)6:292 (Type-species: Phlocochilus palaquius Schedl, monobasic): Schedl, I96.3, Ent. Abh. Ber. Tierk. Dresden 28:263. Synonymy
Phloeotrypetus Wood. 1960, Insects of Micronesia 18(1):16 (Type-species: Phlocotrypetus palauensis Wood, monobasic); Schedl, 1963, Abh. Ber. Tierk. Dresden 28:263. Synonymy
Diagnosis.- In the American fauna Chaetophlocus LeConte is the only group even moderately closely related to this genus. It is distinguished from Chaetophloeus by the much smaller size, by the 4 -segmented antennal funicle, by the unsegmented antennal club, by the different pronotal armature, and by the much more conspicuous strial setae.

Description. - Length $0.75-1.30 \mathrm{~mm}$, 2.0-2.2 times as long as wide. Frons convex in male or in both sexes, females in some species concave and ornamented by setae. Eye oval, rather short, entire; twice as long as wide. Antennal scape not reaching posterior margin of eye, funicle 4 -segmented, club aseptate, without any indications of sutures. Pronotum finely asperate over entire surface, anterior margin in male armed by a pair of teeth. Scutellum not visible; basal margins of elytra armed by five or six pairs of coarse crenulations of about equal size mesad to
striae 5; coarsely striate, declivital sculpture simple. Vestiture of rows of very broad, short, interstrial scales and slender, recumbent, strial setae; interstrial setae umiseriate, broad scales alternating with slender setae.

Distribution. - S United States to Venezuela; S Europe and Asia, and Micronesia. About 23 species are known; 6 of these occur in North and Central America; 2 are from South America.

Biology.- The species are monogamous and phloeophagous. Evidently the male constructs the entrance tunnel and both sexes contribute to the formation of an irregular cavity about 3 mm wide and 5 mm long, engraving both wood and phloem. The eggs apparently are placed in individual niches. The larvae construct individual mines that engrave both wood and phloem and wander without definite direction. The larval mines are rather long and frequently join one another in the later stages. The parent adults may continue to enlarge the egg cavity long after oviposition is complete. In some instances several generations might be completed in the same twig of a living tree.

Notes.- Wollaston originally spelled the name of this genus Leiparthrum (1854), then later, evidently deliberately, changed it to Liparthrum (I864). The apparent reason for the change was an oversight in transliteration in converting the Greek leipo to the Latin lipo. I have regarded the change, apparently correctly, as a valid emendation and have used the spelling that has been applied to this genus consistently in the literature for more than a century, except for Bright (1968). I considered the name Leiparthrum Wollaston (1854) to be a nomen oblitum and replaced it with Liparthrum Wollaston (1864) to preserve stability. An appeal to the Commission upholds my views (Internat. Comm. Zool. Nomencl. 1981:64).

Among the $1 I$ Palaearctic species presently known to me, only arnoldi Semenov shares a distinctive character found in all American species. In these species the uniseriate, interstrial rows of discal setae include broad scales that alternate, at least in part, with slender, recumbent setae similar to those in the strial rows. This unusual character was not mentioned in the key to species in Schedl's (1959) revision of the genus.

Key to the Species of Liparthrum

1. Pronotum with very small, isolated asperities only, devoid of punctures; female frons convex, not ornamented by abundant setae; elytra more slender, 1.4-1.6 times as long as wide
Pronotum with minute asperities and very fine punctures intermixed; female frons concavely impressed and ornamented by rather abundant setae, elytra stouter, 1.2-1.3 times as long as wide
2(1). Elytra stouter, 1.4 times as long as wide; strial punctures coarse, deep, but smaller, interstriae almost as wide as striae; Arizona to Durango; Arbutus; $1.0-1.3 \mathrm{~mm}$
Elytra more slender, 1.5-1.6 times as long as wide; strial punctures very coarse, larger, interstriae about half as wide as striae
3(2). Interstrial setae almost all scalelike, rarely alternating with a slender seta, scales closely set within a row by less than length of a scale, almost all wider than long; lower half of elytral declivity not as steep; pronotal asperities averaging smaller, more numerous; Oaxaca; Thevetia (?); 0.75-0.85 mm
2. cracentis Wood

Scalelike and slender interstrial setae alternating within a row, scales mostly spaced within a row by two or more lengths of a scale, scales more slender, each at least as long as wide; lower half of declivity steeper; pronotal asperities fewer in number but averaging larger
4(3). Smaller; punctures on discal striae smaller, not as deeply, sharply impressed; interstrial scales about as wide as long, slender interstrial setae conspicuously longer than scales; Morelos; Thevetia ovata; 0.8-0.9 mm
3. thevetiae Wood Larger; punctures on discal striae coarse, deeply, sharply impressed; interstrial scales each 1.5-2.0 times as long as wide, equal in length to slender interstrial scales; Baja California; shrub; $1.2-1.3 \mathrm{~mm}$
4. albosetosum (Bright)

5(1). Female frons broadly concave from epistoma to well above upper level of eyes, concavity ornamented by dense, very short, fine pile; strial punctures slightly smaller; elytra slightly more slender; Costa Rica; Ficus; 0.8 mm
5. americanum Wood

- Female frons rather broadly concave from epistoma to upper level of eyes, concavity ornamented by fine, rather long, moderately abundant hair; strial punctures slightly larger; elytra slightly stouter; Mississippi; Maclura; 0.8-1.0 mm

1. Liparthrum arizonicum Wood Fig. 104

Liparthrum arizonicum Wood, 1959, Great Basin Nat. 19:57 (Holotype, male; Miller Canyon, Huachuca Mts., Arizona; Wood Coll.)
Diagnosis.- This species is distinguished from cracentis Wood by the larger size, by the stouter body form, and by the smaller strial punctures and slightly wider interstriae.

Female.- Length $1.0-1.3 \mathrm{~mm}, 2.1$ times as long as wide; body color brown, vestiture and antennae much lighter.

Frons flattened, slightly impressed above epistoma; surface minutely rugulose, without
definite punctures; vestiture rather short, sparse, somewhat more conspicuous along epistoma.

Pronotum 0.70 times as long as wide; widest at base, sides arcuately converging toward rather broadly rounded anterior margin; surface minutely rugulose, evidently without definite punctures (actually, minute punctares present, visible at 200 X ); anterior margins unarmed; very small, isolated asperities uniformly distributed. Vestiture consisting of almost equal numbers of rather short recumbent, stout hair and somewhat shorter semierect, very broad scales.

Elytra 1.4 times as long as wide, 1.9 times as long as pronotum; basal margins each armed by a row of five subcontiguous rather large crenulations mesad of interstriae 4; sides straight and subparallel on basal threefourths, broadly rounded behind; striae not impressed, punctures rather large, close, deep; interstriae narrower than striae, punctures small, uniseriate. Declivity convex, steep; striae somewhat narrower than on disc. Vestiture consisting of rows of rather short recumbent strial hair, and uniseriate rows of somewhat shorter, very broad interstrial scales, each subquadrate scale wider than long and separated from other scales in same row by a space greater than length of a scale, slender setae similar to those of striae alternating with scales in each interstrial row.

Male. - Similar to female except frons more convex above; anterior margin of pronotum armed by a pair of very narrowly separated teeth, about three other successive pairs of pronotal asperities larger.

Distribution- - S Arizona to Durango.
USA: Arizona: Miller Canyon, Huachuca Mts., 22 -VIII-58, Arbutus arizonicus. S. L. Wood. MEXICO: Chihuahua: 37 km S Creel. 18 -VII-60, Arbutus, S. L. Wood; La Laja, I3-VII-60, Arbutus, S. L. Wood. Durango: 16 km W El Salto, 1964, No. 478. J. B. Thomas; La Ciudad. 4-VII-64, Arbutus, D. E. Bright; 14 km E El Palmito, 15-VI-71, Arbutus, D. E. Bright.

## Hosts.- Arbutus arizonicus, A. spp.

Biology. - This species attacks small, unthrifty, or partly broken branches and twigs on living trees. The tunnels are made in the wood immediately below the microscopically thin bark. The above description of tunnels for the genus was based largely on this species.

Notes.- The above treatment was based on the type series of 44 specimens and on 213 other specimens.

## 2. Liparthrum cracentis Wood

Liparthrum cracentis Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):9 (Holotype. female: Niltipec, Oaxaca, Mexico; Wood Coll.)
Diagnosis. - This species is rather closely allied to arizonicum Wood, but it is distinguished by the smaller size, by the more slender body form, and by the larger strial punctures and narrower interstriae.
Female.- Length $0.75-0.85 \mathrm{~mm}, 2.2$ times as long as wide; color brown.

Frons moderately convex, slightly impressed on lower half; surface rather coarsely reticulate, vestiture sparse, more conspicuous toward epistoma, consisting of rather fine, subplumose setae. Eye and antenna as in allied species.

Pronotum 0.81 times as long as wide; widest on basal third, sides weakly arcuate from base, converging on anterior half to rather broadly rounded anterior margin; surface shining, feebly subreticulate, obscure, setiferous granules rather close, in anterior area their anterior margins very finely asperate. Vestiture consisting of truncate, subtriangular scales, each about one and one-half times as long as wide, and equally abundant stout, hairlike setae, each about one and onehalf times as long as scales.

Elytra 1.6 times as long as wide, 1.96 times as long as pronotum; sides almost straight and parallel on basal three-fourths, broadly rounded behind; basal margins each armed by five crenulations mesad of interstriae 4 ; striae not impressed, punctures very coarse, rather deep; interstriae about half as wide as striae, punctures fine, uniseriate, evidently not granulate. Declivity rather steep, convex; sculpture about as on disc. Vestiture consisting of strial rows of slender, recumbent bristles equal in length to scales in interstrial

Fig. 104. Liparthrum spp., dorsal aspect and antenna: 1, arizonicum; 2, 3, albosetosum. (After Bright 1968:639.) See also Fig. 142.
rows; each subquadrate interstrial scale almost as wide as a strial puncture and slightly longer than wide, scales alternating within row with slender recumbent bristles less regularly than in other species.

Male. - Similar to female except pronotum bearing a pair of small, often obsolete, median tubercles on anterior margin, a smaller submarginal pair about one-fourth pronotum length from anterior margin.

Distribution.-S Oaxaca.
MEXICO: Oaxaca: 29 km W Niltipec, 23-VI-67, about 30 m , No. 87, Theretia (?), S. L. Wood.
Biology. - Essentially as described for the genus. Specimens were removed from phloem in twig terminals of a tree having narrow, thick, waxy leaves, with the leaves somewhat concentrated in a whorls at the terminals.

Notes.- The above treatment was based on the type series of 31 specimens.

## 3. Liparthrum thevetiae Wood

Liparthrum thetetiae Wood, 1981, Great Basin Nat. 41:I23 (Holotype, female; Las Piedras Moyotepec, Morelos, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from albosetosum (Bright) by the smaller size, by the smaller, less strongly impressed strial punctures on the disc, and by the more slender interstrial scales.

Female.- Length 0.8-0.9 mm, 2.2 times as long as wide; color very dark brown, vestiture pale.

Frons largely concealed in specimens at hand, convex, apparently about as in albosetosum.

Pronotum about as in albosetosum except asperities slightly larger, scales less abundant, shorter, and wider.

Elytra about as in albosetosum except only three or four basal crenulations present, first three contiguous (five present in albosetosum); strial punctures smaller, less strongly impressed; interstrial scales smaller, little if any longer than wide, spaced within a row by three to five lengths of a scale and alternating within a row with slender setae each about one and one-half times as long as a scale, scales about two-thirds as long as distance between rows.

Distribution.- Morelos.
MEXICO: Morelos: Las Piedras Moyotepec, 17-VII$80,1060 \mathrm{~m}$, Thevetia ovata, T. H. Atkinson.

Notes.- The above treatment was based on the type series of five females.

## 4. Liparthrum albosetum Bright

Fig. 105
Leiparthrum albosetum Bright, 1968, Canadian Ent. I00:638 (Holotype, male; 35 km or 22 miles NW Pénjamo, Baja California, Mexico; California Acad. Sci.)
Diagnosis.- This species is distinguished from arizonicum Wood by the larger strial punctures, by the more slender interstrial scales, by the slightly larger interstrial granules, and by the much more strongly reticulate pronotum.

Male.- Length $1.3 \mathrm{~mm}, 2.2$ times as long as wide; color very dark brown.

Frons as in arizonicum except more distinctly convex, with a distinct, transverse impression above epistoma. Pronotum as in arizonicum except surface rather strongly reticulate.

Elytra 1.5 times as long as wide; essentially as in arizonicum except striae slightly impressed, punctures much larger, deeper; interstriae about half as wide as striae, interstrial granules distinctly larger; interstrial scales more slender, about twice as long as wide.

## Distribution.- Baja California.

MEXICO: Baja California: 35 km or 22 miles NW Pénjamo, 29-VII-59, light trap, K. W. Radford, F. G. Werner; La Paz, 27-111-74, shrub, M. M. Furniss.

Notes. - The above treatment was based on the holotype and on five other specimens.

## 5. Liparthrum americanum Wood

Liparthrum americanum Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):8 (Holotype, female; Río Tempisque, Guanacaste, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from squamosum Blackman by the extensively concave female frons which has dense golden, pilelike hair over the entire surface, by the slightly smaller strial punctures, and by the more slender body form.

Female.- Length 0.8 mm , about 2.1 times as long as wide; color rather light brown.

Frons shallowly concave almost from eye to eye and from vertex to epistoma; surface reticulate; vestiture largely confined to impressed area, consisting of very fine, minute, abundant, pilose hair of uniform length.

Pronotum 0.8 times as long as wide; widest one-third from base, sides moderately arcuate, rather narrowly rounded in front; surface obscured by vestiture, evidently minutely subgranulate and with small setiferous granules uniformly distributed; vestiture consisting of stout recumbent bristles and erect, broad scales in about equal numbers.

Elytra about 1.3 times as long as wide (slightly spread in type), 1.7 times as long as pronotum; sides straight and parallel on basal two-thirds, rather broadly rounded behind; bases each armed by six crenulations mesad of striae 4; striae not impressed, punctures rather large, deep; interstriae almost as wide as striae, weakly convex, moderately large, setiferous punctures uniseriate, each very feebly granulate on anterior side. Declivity steep, convex; striae and interstriae somewhat narrower than on disc. Vestiture consisting of strial rows of short, recumbent, stout hair, and interstrial rows of erect, broad scales; each subquadrate scale almost as wide as long, scales mostly alternating with slender setae similar to those of striae.
Male.-Specimen presumed to be male, with very weakly concave frons devoid of pile; anterior margin of pronotum not armed by a pair of teeth; otherwise as in female.

Distribution.- Costa Rica.
COSTA RICA: Lower Río Tempisque, Guanacaste, 25-III-64, 30 m, No. 501 , Ficus, S. L. Wood: Dominical, Puntarenas, 9-XII-63. $10 \mathrm{~m}, \mathrm{No}$. 297, S. L. Wood.

Biology. - The two specimens were taken from new entrance tunnels in small branches.

Notes. - The above treatment was based on the female holotype and on a male that is presumed to belong to this species.

## 6. Liparthrum squamosum (Blackman)

Figs. 104, 143
Erineosinus squamosus Blackman, 1920, Mississippi Agric. Expt. Sta. Tech. Bull. 9:53 (Lectotype, sex?; Agricultural College or Starkville. Mississippi; U.S. Nat. Mus., 24740, present designation)
Liparthrum squamosum Wood, 1957, Canadian Ent. 89:399.
Diagnosis.- This species is distinguished from americanum Wood by the slightly stouter body form, by the slightly larger strial punctures and, in the female, by the less extensively concave frons, with less abundant, longer frontal vestiture.

Female.- Length $0.8-1.0 \mathrm{~mm}, 2.0$ times as long as wide; color light brown, vestiture pale.

Frons rather deeply concave on median three-fourths from epistoma to upper level of eyes; surface reticulate, minutely punctured; vestiture largely confined to concavity, of very fine, moderately long, rather sparse hair.

Pronotum 0.80 times as long as wide; widest near base, sides rather weakly, convergently arcuate to broadly rounded anterior margin; surface shining, subreticulate, with small, isolated, rounded granules uniformly distributed over entire surface, a few minute, obscure punctures intermixed; vestiture of rather long, slender, recumbent scales over entire surface, a few erect, very broad, short scales intermixed on posterior areas.

Elytra 1.2 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind; basal margins each armed by five or six rather coarse crenulations of equal size mesad of striae 4, no submarginal crenulations; striae not impressed, punctures very coarse; interstriae about half as wide as striae, punctures fine, uniseriate. Declivity steep, convex; striae very weakly impressed, slightly narrower than on disc; interstriae almost as wide as striae, weakly convex. Vestiture consisting of short, recumbent, coarse strial setae, one from each puncture; and erect, very broad scales in uniseriate, interstrial rows, each scale subquadrate, as wide as long, scales alternating in a row with slender, recumbent setae similar to those of striae.

Male.-Similar to female except frons convex, more coarsely punctured, vestiture reduced in abundance and length; anterior margin of pronotum armed by a pair of teeth, anterior slope of pronotum with about a dozen asperities.

## Distribution. - Mississippi.

USA: Mississippi: Agricultural College (Starkville), 20,21-II, 19-20-V. Toxylon pomiferum, M. W. Blackman; Holly Springs, 25-VIII, 21-IX. Osage Orange, C. J. Drake.

## Host.- Maclura pomifera.

Biology.-According to Blackman (1920:53), the habits are about as described for the genus. The tunnels were almost entirely in the phloem and larval mines tended to be longitudinal.

Notes.- The above treatment was based on 16 syntypes and on 14 other specimens. This species was described from 16 syntypic specimens from Agricultural College. The Holly Springs "paratypes" must be regarded
as no more than Blackman's metatypes. The syntype specimen labeled "type, 24740," in the U.S. National Museum has never been so designated; I here designate that specimen as the lectotype of this species.

Polygraphidae Chapuis, 1869, Synopsis des Scolytides, p. 48 (Type-genus: Polygraphus Erichson, 1836) Carphoboridae Nüsslin, 1912, Verh. deutsch. Naturf. Arzte 1911:430 (Type-genus: Carphoborus Eichhoff, 1964)

Anatomical features.- The frons is sexually dimorphic, with the male variously impressed, the female flat or convex and usually ornamented by hair, the eye is emarginate to divided, the antennal funicle is $5-6$-segmented, the club is asymmetrical, flattened, and with or without sutures, the procoxae are contiguous, the third tarsal segments are slender, the pronotum is unarmed, the scutellum is not visible, and the crenulations at the bases of the elytra extent laterally to the humeral angle.

Biological features. - All are phloeophagous. Carphobius is monogamous, the other genera are polygynous. Parental tumnels have a large nuptial chamber; they are monoramous in Carphobius and of the radiate type in the other genera. Eggs are deposited in niches. Larval mines have a greater tendency to cross one another than is seen in most other tribes. Symbiotic relationships with other genera have not been reported.
Taxonomy.-American Carphoborus and Polygraphus are restricted to Abietineae hosts in northern North America and undoubtedly were derived from the Eurasian-African area, where both genera are well represented. Carphobius is unique to the Cupressineae from Arizona to Guatemala, where it appears to be a relic of a former age. An exchange of Carphoborus and Polygraphus species between North America and Asia appears to have taken place rather recently; in fact, Polygraphus rufipennis (Kirby) and poligraphus (Limnaeus) are distinguished with considerable difficulty. The three American genera
are quite distinctive and rather easily distinguished from one another.

## Genus Carphobius Blackman

Carphohius Blackman, 1943, Proc. U.S. Nat. Mus. 94:398 (Type-species: Carphohius arizonicus Blackman, monobasic)
Diagnosis.- This genus superficially resembles Phloeosinus, but it is distinguished by the 6 -segmented antennal funicle, by the shallowly emarginate eye, and by the transverse sutures of the antennal club. It evidently is much more closely related to Carphoborus and Polygraphus.

Description.- Length $1.6-2.1 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown. Frons convex in female, impressed in male. Eye elongate, shallowly emarginate. Antennal scape elongate, not reaching posterior margin of eye; funicle 6-segmented; club with three transverse sutures, first septate. Pronotum wider than long, unarmed. Scutellum reduced, not visible. Crenulations at elytral bases extending from interstriae 1 to 7 ; elytra striate, interstriae punctate; declivity unarmed or armed in male. Vestiture hairlike. Fore coxae contiguous; precoxal ridge on prothorax obsolete. Third tarsal segments wide, bilobed.

Distribution.- Two species are known; they occur from Arizona to Guatemala.

Biology. - These are monogamous, phloeophagous species that occur in small broken or cut branches of their host trees.

## Key to the Species of Carphobius

1. Elytral declivity rather strongly bisulcate, male interstriae 3 armed by a row of teeth; surfaces subshining, vestiture rather coarse; frons more coarsely punctured; Arizona and New Mexico to Durango; Juniperus deppeana, $1.6-2.1 \mathrm{~mm}$

- Elytral declivity convex, unarmed; surface appearing brightly polished, vestiture finer; frons more finely punctured; Guatemala; Cupressus lucitanica; $2.2-3.2 \mathrm{~mm}$

2. cupressi Wood

## 1. Carphobius arizonicus Blackman

 Fig. 105Carphobius arizonicus Blackman, 1943, Proc. U.S. Nat. Mus. 94:398 (Miller Canyon, Huachuca Mts., Arizona; U.S. National Mus., 56575)
Diagnosis.- This unique species bears a superficial resemblance to some small Phloeosinus, but the body is more slender, the elytral armature quite different; the characters summarized in the above key distinguish it from cupressi Wood.

Female.- Length $1.6-2.1 \mathrm{~mm}, 2.23$ times as long as wide; color dark brown.

Frons convex, central half of area below upper level of eyes flattened to weakly impressed; epistomal margin weakly elevated, a broad, short premandibular lobe present but not bilobed; surface smooth, shining, punctures fine, deep, rather close, somewhat reduced toward center; vestiture fine, hairlike, rather sparse, uniformly distributed.

Pronotum 0.80 times as long as wide; widest at base, sides weakly arcuate, converging to a rather well-developed constriction just before broadly rounded anterior margin; surface unarmed, smooth, shining, punctures coarse, very deep, close, separated by less than diameter of a puncture; vestiture rather fine, hairlike, long, rather abundant.

Elytra 1.45 times as long as wide, 2.0 times as long as pronotum; bases of elytra arcuate, each armed by nine crenulations, scutellar notch broad, rather well-developed, but scutellum not evident on surface of closed elytra; striae 1 slightly impressed, others not impressed, punctures rather large, moderately deep; interstriae slightly wider than striae, very feebly convex, surface subreticulate, punctures rather fine; confused, a median row on each interstriae very slightly larger. Declivity steep, convex, impressed between third interstriae; interstriae 1 and 3 slightly elevated, unarmed, 2 flat and impressed on median side. Vestiture hairlike, short, abundant, with a median row on each interstriae somewhat longer, erect.

Male. - Similar to female except frons transversely impressed; third declivital interstriae more strongly elevated, particularly
below, and armed by about four rather large, slender teeth that increase in size posteriorly.

Distribution.- Arizona and New Mexico to Durango; probably also in W Texas, since the host occurs there.

USA: Arizona: Carr Canyon, Huachuca Mts., 8-VIII62; Miller Canyon, Huachuca Mts., 27-VIII-07, H. A. Kaeber, and 8-VIII-62. New Mexico: Ruidoso, 8-X-40, R. L. Furniss. MEXICO: Chihuahua: 37 km S Creel, I8-VII-60; 37 km E Maguarichic, I3-VII-62. Durango: 37 km W Durango, 4-VI-65, 2000 m , No. 19; 5 km W El Salto, 7-VI-65, No. 40. All taken by me from Alligator juniper except as noted.

Ноst.-Juniperus deppeana.
Biology.- This beetle usually selects for attack dying branches less than 3 cm in diameter on living trees, particularly branches girdled by Cerambycidae. The beetles are monogamous, and they construct a longitudinal, monoramous gallery with nuptial chambers and egg niches essentially as in most Phloeosinus species. The egg gallery engraves the wood rather deeply and the larval mines do so moderately, due to the thin bark on small branches. Larval mines of moderate length wander in the general direction away from the parental tunnel.

Notes.- The above treatment was based on the holotype, allotype, 3 paratypes, and 56 other specimens.

## 2. Carphobius cupressi Wood

Carphobius cupressi Wood, 1974, Brigham Young Univ, Sci. Bull., Biol. Ser. I9(I):I2 (Holotype, male; I1 km N San Marcos, San Marcos, Guatemala; Wood Coll.)
Diagnosis.- This species is distinguished from arizonicus Blackman by the larger size, by the more finely punctured frons, by the convex elytral declivity, by the absence of denticles on the declivity, by the brightly polished appearance, by the finer vestiture, and by many other characters.

Male.- Length $2.2-3.2 \mathrm{~mm}, 2.3$ times as long as wide; color very dark brown, almost black, elytra dark reddish brown.

Frons strongly, transversely impressed just below middle, impression extending to upper level of eyes, epistoma strongly raised and bearing a broad premandibular lobe, a small
median tubercle at base of lobe; surface of impressed area very smooth, brightly shining, very finely punctured on lower third, punctures slightly larger above; vertex reticulate, dull. Eye shallowly emarginate, finely granulate. Antennal scape elongate; funicle 6 -segmented, longer than scape; club as long as scape, 1.5 times as long as wide, with three straight, transverse sutures.

Pronotum 0.90 times as long as wide; widest near base, sides rather weakly arcuate and converging slightly on basal half, rather strongly constricted laterally just before broadly rounded anterior margin; surface smooth, brightly shining, punctures coarse, deep, close. Vestiture of fine, moderately long, rather abundant hair.

Elytra 1.6 times as long as wide, 2.1 times as long as pronotum; scutellum not exposed; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; each basal margin strongly arcuate and armed by about 16 crenulations, submarginal crenulations poorly developed: striae not impressed, punctures coarse, deep; interstriae smooth, shining, as wide as striae, punctures fine, deep, confused, rather numerous. Declivity rather steep, convex; sculpture about as on dise except strial punctures slightly smaller; interstrial punctures devoid of granules. Vestiture of fine, rather short, abundant strial and interstrial hair, and interstrial rows of similar but slightly longer hair. Third tarsal segments broad, bilobed.

Female.- Similar to male except frons convex, with a slight central impression.

Distribution.-Guatemala.
Guatemala: 11 km N San Marcos, San Marcos, 23-11-72, Cupressus lucitanica, E. W. Clark.

Host.- Cupressus lucitanica.

Fig. 105. Carphohius arizonicus: 41, female; 42, male; 43, female head; 44, male head; 45, antenna. (After Blackman 1943:pl. 17.)

Biology. - Specimens were taken from the bark of recently cut branches.

Notes.- The above treatment was based on the type series of 19 specimens.

## Genus CARPHOBORUS Eichhoff

Carphoborus Eichhoff, 1864, Berliner Ent. Zeitschr. 8:27 (Type-species: Hylesinus minimus Fabricius, monobasic)
Estenohorus Reitter, 1913, Wiener Ent. Zeit. 32(Beiheft):58 (Type-species: Hylesinus perrisi Chapuis, monobasic)
Diagnosis.- This species is distinguished from Polygraphus Erichson by the 5 -segmented antennal funicle, by the presence of two sutures on the antennal club, and by the deeply emarginate eye.

Description.- Length $1.4-2.6 \mathrm{~mm}$, 2.2-2.6 times as long as wide; color almost black. Frons dimorphic, females shallowly concave to moderately convex, ornamented by abundant setae, males impressed above eyes, a conspicuous, transverse, usually bituberculate elevation near upper level of eyes, vestiture sparse, inconspicuous. Eye elongateoval, about 2.3 times as long as wide, deeply emarginate. Antennal scape elongate; funicle 5 -segmented; club varying from narrow and symmetrical to broad and moderately asymmetrical, two definite sutures, and a third indefinite suture indicated. Pronotum about 0.83 times as long as wide; widest near base, a distinct lateral constriction just before anterior margin; sculpture simple; punctures moderately small, abundant; vestiture of small erect scales. Elytra about 1.7 times as long as wide; basal margins armed by about nine crenulations, submarginal crenulations also present; striate, strial punctures coarse; interstriae often subgranulate, dentate on declivity, alternate interstriae usually elevated. Vestiture of conspicuous, small, interstrial scales, and minute, inconspicuous strial hair. Third tarsal segments cylindrical.

Distribution.- N North America, North Africa, Europe and N Asia; of the 34 species known, 20 occur in North America.

Biology.- The species of Carphoborus are polygynous and phoeophagus. They attack small, shaded-out branches of living trees or the boles of small, suppressed, unthrifty trees. Most species live in host tissues drier and more completely dead than those preferred by most bark beetles. An apparent exception
is pinicolens Wood, which may be capable of killing healthy seedlings in a desert scrub forest. The male constructs the entrance tunnel and a large nuptial chamber. Three to about eight females join him and construct straight or slightly sinuate egg galleries that radiate out from the nuptial chamber. These parental galleries engrave the wood deeply; about two-thirds of the diameter of the tunnel is in the wood. The large eggs are deposited individually in niches and packed with a
brownish frass presumably derived from the phloem. The larval mines wander indiscriminately in the phloem; they are usually very short, but are not always so. The young adults may feed in the brood tunnels for long periods of time before emerging from the host. Three successive generations were reared in the laboratory from the same piece of wood; it is doubtful this habit would be repeated in nature except under unusual circumstances.
(Modified from Wood 1954)

1. Antennal club large, broad, less than 1.2 times as long as wide (except simplex); female frons impunctate and glabrous on a moderately large median area; transverse impression of male frons more conspicuous and extensive, median elevation large and prominent

- Antennal club small, slender, 1.3 or more times as long as wide (also see simplex); female frons punctate or granulate, pubescent over entire surface; male frons usually less strongly impressed below, median elevation smaller, often absent9
2(1). Female frons flattened, frontal pubescence long, setae on or near vertex much more than half as long as scape. ..... 3
- Female frons convex, frontal pubescence short, setae on vertex less than one- fourth as long as scape ..... 8

3(2). Declivital interstriae 2 as wide as 1 and 3, usually convex; declivital interstriae $1,3,5,7$, and 9 less strongly elevated, more finely or not at all serrate; California; Pseudotsuga macrocarpa; 1.9-2.2 mm

- Declivital interstriae 2 distinctly narrower than one or three, flat, alternate declivital interstriae usually more strongly elevated, serrations larger4

4(3). Antennal club smaller, more slender, 1.2 times as long as wide; interstriae 2 becoming obsolete on upper half of declivity; declivital interstriae 3 more strongly elevated; California to Baja California; Pinus lambertiana, P. sabiniana; $1.8-2.4 \mathrm{~mm}$
6. simplex Leconte

- Antennal club larger, broad; declivital interstriae 2 narrow, continuing to near apex; declivital interstriae 3 only slightly elevated (except mexicanus)5
5(4). Sutures on antennal club more strongly oblique, 1 weakly, 2 more strongly procurved; declivital interstriae 3 and 9 weakly convex ..... 6
- Sutures of antennal club transverse, straight to weakly arcuate; declivital interstriae more conspicuously elevated ..... 7

6(5). Female frons almost flat, impunctate, glabrous area occupying central fourth, pubescence more abundant, slightly longer; tubercles on elytral declivity finer; British Columbia to California; Pseudotsuga menziesii; 1.8-2.6 mm
2. vandykei Bruck

- Female frons moderately convex, impunctate, glabrous area occupying more than central half; declivital tubercles larger; S California to S Nevada; Pinus edulis, $P$. monophylla; 1.8-2.5 mm

3. frontalis Wood

7(5). Declivital interstriae 1, 3, and 9 weakly elevated, all less than half as high as wide; discal interstriae very slightly wider than striae; Wyoming and New Mexico to Oregon and California; Pinus; $1.7-2.5 \mathrm{~mm}$
4. pinicolens Wood

- Declivital interstriae 1, 3, and 9 rather strongly elevated, 3 at least as high as wide; discal interstriae distinctly narrower than striae; Durango; Pinus lumholzii: 1.8 mm
$8(2)$. Female frons feebly convex, central impunctate, glabrous area occupying median fourth; declivital interstriae 2 continuing to near apex; Wyoming and Utah; Picea pungens; $1.8-2.2 \mathrm{~mm}$
- Female frons more strongly convex, central impunctate, glabrous area occupying more than median half; interstriae 2 becoming obsolete on upper half of declivity; SE Arizona and SW New Mexico to Durango; Pinus edulis, P. leiophylla; $1.8-2.5 \mathrm{~mm}$

8. convexifrons Wood
9(1). Interstriae 9 not elevated or serrate posterior to base of declivity ..... 10

- Interstriae 9 elevated and serrate to junction with 3 ..... 12

10(9). Declivital interstriae 3 more strongly, broadly elevated, serrations small, confused, more abundant on sides of elevation than on its summit; Michigan to New Brunswick; Picea rubens, Larix laricina; 1.6-1.9 mm .............. 11. dunni Swaine

- Declivital interstriae 3 less strongly, more narrowly elevated, serrations larger, confined to summit
11(10). Declivital interstriae 1 moderately elevated, serrate, 3 only slightly more strongly elevated than 1 , of almost uniform height or highest near middle of declivity; Alberta to Utah and Colorado: Picea engelmannii, P. pungens; $1.8-2.1 \mathrm{~mm}$

9. sansoni Swaine

- Declivital interstriae 1 usually not elevated or serrate (oceasional exceptions), 3 much more strongly elevated than 1 , height of elevation increasing to its apex, declivital teeth usually more slender; Alaska to Northwest Territories; Picea glauca; 1.8-2.2 mm

10. andersoni Swaine

12(11). Female frons flattened or concave, rather coarsely punctured; declivital teeth on interstriae 3 very coarse, longer than height of elevation of this interstriae; declivital interstriae $2,4,6$, and 8 never serrate 13

- Female frons flattened or convex, punctate or granulate; deelivital teeth fine, those on interstriae 3 much shorter than height of this interstriae; evennumbered declivital interstriae sometimes serrate 14
13(12). Female frons broadly concave, very coarsely punctured; male frons with a prominent, median, tuberculate elevation; declivital interstriae 1,3 , and 9 less strongly elevated, teeth less numerous and smaller; California; Pinus radiata; $1.8-2.4 \mathrm{~mm}$ 12. radiatae Swaine
- Female frons flattened, often with a small, very narrow, deep, median groove, punctures not as coarse; male frons usually devoid of tuberculate elevation; declivital teeth more numerous, larger; British Columbia and Montana to California and Utah; Pinus contorta, P. ponderosa; 1.8-2.1 mm

13. ponderosac Swaine

14(12). Declivital interstriae 4,6 , and 8 finely serrate; female frons at least weakly
convex, finely granulate, never shining and punctured ........................................ 15
Declivital interstriae 4, 6, and 8 never serrate (weakly serrate in intermedius);
female frons flattened and punctured, or convex and granulate ........................... 16
15(14). Declivital interstriae 2 rather broad, serrate; female frons evenly, weakly convex; California; Pinus contorta; $1.7-2.0 \mathrm{~mm}$

- Declivital interstriae 2 very narrow, not serrate; female frons rather strongly
convex; Arizona; Pseudotsuga menziesii; 2.1 mm ................. 15. pseudotsugae Wood

16(14). Discal interstriae as wide or wider than striae; pronotal and elytral scales
distinctly larger, apparently less abundant ................................................................ 17

- Discal interstriae narrower than striae; declivital teeth small to very small; pronotal and elytral scales smaller, apparently more abundant

17(16). Female frons more strongly impressed, frontal vestiture finer, much longer in marginal areas than at center; declivital interstriae 3 as high as wide; Alaska to Oregon and Colorado; Picea engelmannii (Pinus contorta?); $1.9-2.1 \mathrm{~mm}$
16. intermedius Wood

- Female frons flattened, frontal vestiture coarse, rather short, of uniform length; declivital interstriae 3 wider than high18

18(17). Declivital interstriae 1 and 3 rather weakly elevated, their denticles coarse, much longer than height of interstriae; Utah; Pinus ponderosa; 1.8-2.2 mm $\qquad$
17. perplexus Wood

- Declivital interstriae 1 and 3 slightly higher, their denticles small, not as long as height of interstriae; Oregon; Picea engehmannii; 1.7 mm ............ 18. piceae Wood
19(16). Female frons flattened, shining, rather finely, closely punctured, pubescence longer, fine, less abundant; declivital interstriae 3 moderately elevated; interstriae 5 and 7 fused apically; Alaska and Northwest Territories to Wyoming and New Brunswick; Picea; 1.4-2.1 mm

19. carri Swaine

- Female frons convex, opaque, finely granulate, frontal vestiture short, abundant; declivital interstriae 3 very strongly elevated, elevation curving after junction with 9 and continuing to sutural apex; interstriae 5 and 7 ending separately; Missouri and New York to Mississippi and Florida; Pinus; 1.4-1.8 mm ...

20. bifurcus Eichhoff

## 1. Carphoborus blaisdelli Swaine Fig. 10 s

Carphoborus blaisdelli Swaine, 1924, Canadian Ent. 56:234 (Holotype, male: Camp Baldy, San Bernardino Co., California; Canadian Nat. Coll., 820)

Carphoborns cressatyi Bruck, 1936, Bull. California Acad. Sci. 35:36 (Holotype, male; Arroyo Seco, Los Angeles Co., California: California Acad. Sci. Coll.); Wood, 1954, Canadian Ent. 86:509. Synonymy
Diagnosis.- This species is distinguished from vandykei Bruck by having declivital interstriae 2 as wide and as high as 1 or 3 .

Female.- Length 1.9-2.2 mm, 2.2 times as long as wide; color dark brown to black.

Frons flattened on central three-fourths from well above eyes to just above epistoma, epistomal margin elevated, with a moderately large premandibular lobe, surface of flattened area reticulate, with rather close, deep, small punctures except impunctate on median fourth, extreme lateral and dorsal areas more coarsely sculptured; vestiture
confined to punctured area, rather long and abundant in peripheral areas, epistomal brush conspicuous. Antennal club moderately asymmetrical, sutures 1 and 2 suboblique, weakly to moderately arcuate.

Pronotum 0.83 times as long as wide; widest near base, sides on basal half almost straight, rather strongly constricted before broadly rounded anterior margin; surface very closely, deeply, rather coarsely punctured. Vestiture of abundant, small, erect scales.

Elytra 1.7 times as long as wide; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; each basal margin armed by nine crenulations and several smaller submarginal crenulations at bases of interstriae $2-5$; striae weakly impressed, punctures rather coarse, close, deep; interstriae slightly wider than striae, weakly convex, punctures close, deep, rather coarse, confused. Declivity steep, convex; interstriae l-3 moderately, equally convex, 3 slightly
higher on lower half in some specimens, 1,3 , 5,7 , and 9 armed by small, pointed teeth. Vestiture of abundant, small, erect scales.

Male.- Similar to female except frons rather strongly, transversely impressed on lower half, with bituberculate, median elevation at upper level of eyes, surface rather coarsely, closely punctured; vestiture short, stout.

## Distribution.-S California.

USA: California: Arroyo Seco, Los Angeles Co., 25-XII-33, C. R. Bruck; Mt. Wilson, Los Angeles Co., 15-VII-24, W. Benedict; Pasadena, Los Angeles Co.; Camp Baldy, San Bernardino, 17-VII-I4; Keen Camp, San Jacinto Mts.; Santa Paula, Ventura Co.; Sierra Madre Mts., 15-VIII-24; Switzers Camp, San Gabriel Mts.; all from the same host.

Host.- Pseudotsuga macrocarpa.
Biology. - Apparently this species breeds only in unthrifty branches of living trees.

Notes. - The above treatment was based on the holotype, 21 paratypes of blaisdelli, and 149 other specimens.

## 2. Carphoborus vandykei Bruck Figs. 107, 108

Carphoborus candykei Bruck, 1933, Canadian Ent. 65: 104 (Holotype, male: Mount St. Helena, California: Ohio State Univ. Coll.)
Diagnosis.- This species has the antennal sutures weakly procurved as in blaisdelli Swaine, but it is distinguished by having declivital interstriae 2 flat and narrower than 1 or 3. Declivital interstriae 3 and 9 are less strongly elevated than in pinicolens Wood, in addition to the antennal character mentioned in the above key.

Female.- Length $1.8-2.6 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to almost black.

Frons, pronotum, and elytral disc as in blaisdelli except frontal vestiture somewhat shorter. Elytral declivity differing from blaisdelli as indicated in above diagnosis.

Male.-Similar to female except frons as in male blaisdelli.

Distribution.-S British Columbia to central California.

CANADA: British Columbia: Qualicum, I8-II-23; Pender harbour, 8-V-28, G. R. Hopping. USA: California: Burney, Shasta Co., II-VI-6I, S. L. Wood; Calistoga, 5-X-47, S. L. Wood; Deadhorse Summit, Siskiyou Co., I5-VI-6I, s. L. Wood; Del Norte Co., 22-V-37, R. L. Furniss; French Hill 22-V-37, R. L. Furniss; Mt. St. Helena 29-III-39, C. R. Bruck; Quincy; $6 \mathrm{mi}(10 \mathrm{~km}) \mathrm{N}$ Willets, 9-V-46, T. O. Thatcher; Yosemite N. P. All from Douglas fir. Oregon: Ashland; Oregon Caves; St. Helen; Waldo.

## Host.- Pseudotsuga menziesii.

Biology.- This species breeds in the lower, unthrifty branches of living trees.

Notes.- The above treatment was based on the holotype, 41 paratypes, and 19 other specimens.

## 3. Carphoborus frontalis Wood

Carphoborus frontalis Wood, 195t, Canadian Ent. 86:515 (Holotype, female; Ventura County, California; U.S. Nat. Mus.)
Diagnosis.- This species has the sutures on the antennal club weakly procurved as in vandykei Bruck, but it is distinguished by the moderately convex female frons, with a much larger, impunctate, central area, and by the very slightly larger strial punctures and declivital denticles.

Female.- Length $1.8-2.5 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown to black.

Frons as in blaisdelli except broadly convex, central glabrous, impunctate area occupying more than central half, vestiture

Fig. 106. Carphoborus pinicolens, female. (After Bright 1973:155.)

Fig. 107. Carphoborus spp.: 1, candykei, protibia, 2, same, metatibia, 3, same, antennal club; 4, ponderosae, antenna; 5, pinicolens, antemal club, 6, bifurcus (setae and strial punctures omitted), 7. same, face of declivity. (After Wood 1954:503.)
coarser, slightly shorter. Pronotum and elytral dise as in blaisdelli except striae less distinctly impressed, punctures slightly larger, interstriae almost flat. Elytral declivity as in vandykei except denticles averaging slightly larger.

Male- Similar to female except frons differing as in blaisdelli.

Distribution.-S California and $S$ Nevada.

USA: California: Frazier Mt., 6-1X-40, A. T. McClay: Pasadena. 22-II-24: Valyermo, 17-1-36, 26-I-37, A. T. MeClay; Ventura Co., 17-I-05, lot 27Tg. A. D. Hopkins; Wrightwood. San Bernardino Co. Nevada: $25 \mathrm{mi}(40 \mathrm{~km})$ NIW Las Vegas, 10-VI-69, W. G. Harwood. All from the same host.

Host.- Pinus monophylla.
Biology.- Presumably reared from branches.

Notes. - The above treatment was based on the holotype, on 16 paratypes, and on 23 other specimens.

The series from which the type was selected was labeled Pinus edulis; however, the nearest native stand of that host occurs several hundred miles east of the type locality.

## 4. Carphoborus pinicolens Wood Figs. 106, 107, 108

Carphoborus pinicolens Wood, I954, Canadian Ent. 86:512 (Holotype, female: Logan Dry Canyon. Utah; U.S. Nat. Mus.)
Carphohorus tuberculatus Bright, 1964, Pan. Pacific Ent. 40:165 (Holotype, female; Crooked Creek, Mono Co., California; California Acad. Sci.); Wood. 1977. Great Basin Nat. 37:384. Synonymy

Diagnosis.- This species is very closely related to vandykei Bruck, but it is distinguished by the straight suture 1 of the antennal club, by the more strongly elevated declivital interstriae 3 and 9 , and by the larger, more numerous denticles on the elytral declivity.

Female.- Length $1.7-2.5 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to black.

Frons, pronotum, and elytra as in vandykei except frontal vestiture coarse, shorter, strial punctures very slightly larger, and declivital interstriae 1,3 , and 9 usually slightly higher with denticles averaging slightly larger; antennal club with sutures 1 and 2 almost straight.

Male- - Similar to female except differing as in blaisdelli.

Distribution.- Oregon and Wyoming to California and New Mexico.
USA: Arizona, California. Colorado, Idaho, Nevada, New Mexico, Oregon, Utah, Wyoming.

Hosts.-Pinus aristata, P. cembroides, $P$. edulis, P. flexilis, P. jeffreyi, P. lambertiana, P. leiophylla, P. monophylla, P. ponderosa.

Biology.- This species breeds in unthrifty, cut, or broken branches or tops and unthrifty or injured seedlings. In several instances apparently healthy seedlings on poor sites were killed.

Notes.- The above treatment was based on the holotype and 85 paratypes of pinicolens, on the holotype and a long series of paratypes of tuberculatus, and on 104 other specimens.

Seventy percent of the females taken at the type locality have a small tubercle in the center of the frons. This character also appeared in single females from Beaver and Long Hollow, Utah, as well as in the type series of tuberculatus.

## 5. Carphoborus mexicamus Bright

Carphoborus mexicanus Bright, 1972, Canadian Ent. 104:1491 (Holotype, female; 14 km or 9 miles E El Palmito, Durango, Mexico; Canadian Nat. Coll., 12605)
Diagnosis.- This species is distinguished from pinicolens Wood by the smaller size, by the strongly elevated declivital interstriae 1 , 3 , and 9 , and by the larger, deeper strial punctures.

Female.- Length $1.8 \mathrm{~mm}, 2.2$ times as long as wide; color almost black, vestiture pale.

Frons as in frontalis except vestiture longer, some setae as long as scape. Antennal club as in pinicolens.

Pronotum and elytra as in pinicolens, except strial punctures much larger, deeper, striae distinctly wider than interstriae, interstriae $1,5,7$, and 9 more strongly elevated, about half as high as wide, 3 much higher, as high as wide near its apex, 3 and 9 fused at their junction. Scales slightly smaller than in pinicolens.

## Distribution.- Durango.

MEXICO: Durango: 9 miles or 44 km E El Palmito, 15-VI-7I, 2500 m , Pinus humholzii, D. E. Bright.

## Host. - Pinus lumholzii.

Notes.- The above treatment was based on the holotype.

Fig. 108. Carphohorus spp., elytral declivities, dorsal and caudal aspects: 8, 9, blaisdelli; 10, 11, vandykei; 12, 13, pinicolens; 14, 15, simplex; 16, convexifrons; 17, declitis; 18, pseudotsugae; 19, intermedius. (After Wood 1954:511.)

## 6. Carphoborus simplex LeConte

 Fig. 108Carphohorus simplex LeConte, 1876. Proc. Amer. Philos. Soc. 15:383 (Lectotype, female; Mojave Desert, California: Mus. Comp. Zool., 979, present designation)
Carphoborus swainei Bruck, 1933, Canadian Ent.. 65:105 (Holotype, male; Mt. Diablo, California; Ohio State Univ. Coll.); Wood, 1954, Canadian Ent. 86:513. Synonymy
Diagnosis. - This species has the frons essentially as in pinicolens Wood, the declivity as in convexifrons Wood, and the antennal club more slender than either of these.

Female.- Length 1.8-2.4 mm, 2.3 times as long as wide; color dark brown to black.

Frons as in pinicolens, with central impunctate area occupying central half; vestiture less abundant, longer, slightly finer. Antennal club slender, 1.2 times as long as wide; sutures almost straight. Pronotum and elytral disc as in pinicolens; elytral declivity with interstriae 2 very narrow, obsolete on lower half; 1 moderately, 3 more strongly elevated, about half as high as wide, $1,3,5,7$, and 9 finely serrate.

Male. - Similar to female except frons differing as in blaisdelli.

Distribution.-California to Baja California.

USA: California: numerons localities southward from Shasta Co. MEXICO: Baja California: San Isidro, 1-XI47.

Hosts. - Pinus sabiniana, one record each from $P$. ieffreyi, and $P$. ponderosa.

Brology.- This species breeds in small, unthrifty branches of living trees.

Notes. - LeConte's species was based on more than one specimen. I here designate the first, a female bearing the type label and type number 979 in the LeConte Collection at the Museum of Comparative Zoology, as the lectotype of Carphoborus simplex LeConte. The above treatment was based on the lectotype of simplex, on the holotype and 44 paratypes of swainei, and on 367 other specimens.
7. Carphoborus brevisetosus Wood

Carphoborus brecisctosus Wood, 1954, Canadian Ent. 86:514 (Holotype, female; Saratoga, Wyoming: U.S. Nat. Mus.)

Diagnosis.- This species is distinguished from pinicolens Wood by the slightly convex
female frons, by the much shorter frontal vestiture on the female, and by the less strongly elevated declivital interstriae 3 and 9 , with their tubercles finer.

Female.- Length $1.8-2.1 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to black.

Frons as in pinicolens except feebly convex, vestiture short, less abundant, longest setae about equal in length to width of scape: antennal club more slender, 1.2 times as long as wide. Pronotum and elytral dise as in pinicolens; declivity with interstriae 3 and 9 less strongly elevated, tubercles finer.

Male.-Similar to female except frons differing as in blaisdelli.

Distribution.- Wyoming to Utah.
USA: Utah: Mckee Draw, Ashley N.F.. 16-VI-60; Parowan Canyon, 2()-VI-60; Sanford Canyon, Dixie N.F., 22-VI-60, all from Picca pungens, by S. L. Wood. Wyoming: Saratoga, 2S-V'II, lot 955-2, Picea pungens, D. DeLeon, 17-V11, Hopk. U.S. 31529e.

Ноst.- Picea pungens.
Biology.- All specimens were taken from unthrifty, shaded-out branches of living trees.

Notes.- The above treatment was based on the type series of 6 specimens and on 90 other specimens.

## 8. Carphoborus convexifrons Wood <br> Fig. 10 S

Carphohorus contexifrons Wood, 1954, Canadian Ent. S6:516 (Holotype, female; Chiricahua Nat. Mon., Arizona; U.S. Nat. Mus.)
Diagnosis.- This species is closely allied to frontalis Wood, but it is distinguished by the more strongly convex female frons, with very short frontal vestiture, by the narrow, almost obsolete declivital interstriae 2, and by the more strongly elevated interstriae 3 .

Female.- Length $1.8-2.5 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to black.

Frons moderately convex, a narrow, transverse impression immediately above epistoma; central half impunctate and glabrous, peripheral areas rather coarsely, deeply punctured; vestiture coarse, short, setae shorter than thickness of antennal scape, epistomal brush longer. Antennal club broad, sutures 1 and 2 very feebly arcuate.

Pronotum and elytral disc essentially as in frontalis; elytral declivity similar to that of frontalis except interstriae 2 very narrow, almost obsolete, interstriae 3 and 9 more strongly elevated, about half as high as wide;
declivital denticles on interstriae $1,3,5,7$, and 9 comparatively small.

Male.- Similar to female except frons differing as in blaisdelli.

Distribution.- SE Arizona and SW New Mexico to Durango and Coahuila.

USA: Arizona: Chiricahua Nat. Mon., 1-X-36, lot 8382, Pinus leiophylla, D. DeLeon; Santa Catalina Mts., lots 7703. 7705, M. Chrisman. New Mexico: Peloncillo N.F., 12-XI-07 (bred 6-1-08), Hopk. U.S. 5593, P. edulis, J. L. Webb. MEXICO: Chihuahua: La Pinta, pinyon. Coahuila: 18 miles or 29 km SE Saltillo, 21-V-7i, P. cembroides, D. E. Bright. Durango: 30 km W Durango, 19-VI-71. P. cembroides, D. E. Bright.

Hosts.-Pinus edulis, P. cembroides, and P. leiophylla.

Notes. - The above treatment was based on the type series of 20 specimens and on 43 other specimens.

## 9. Carphoborus sansoni Swaine

Fig. 109

Carphoborus sansoni Swaine, 1924, Canadian Ent. 56:235 (Holotype, male; Banff, Alberta; Canadian Nat. Coll., 822)
Carphoborus engelmanni Wood, 1951, J. Ent. Soc. Kansas 23:31 (Holotype, female); Logan Dry Canyon, Utah; U.S. Nat. Mus.); Wood, 1954, Canadian Ent. 86:517. Synonymy
Diagnosis. - This species is very closely allied to andersoni Swaine, but it is distinguished by the more strongly elevated and serrate declivital interstriae 1 and the less strongly elevated declivital interstriae 3 , particularly on the apical half.
Female.- Length $1.8-2.1 \mathrm{~mm}, 2.4$ times as long as wide; color almost black.

Frons flattened on central half; surface closely, deeply, rather finely punctured over entire surface; vestiture coarse, uniformly rather short, uniformly distributed. Antennal club 1.3 times as long as wide; sutures straight, suboblique. Pronotum and elytral disc essentially as in blaisdelli Swaine except interstriae $1,3,5$, and 7 each with a row of granules on posterior half; elytral declivity with interstriae 1 moderately elevated, rather coarsely serrate, 2 very narrow, flat, 3 more strongly elevated than 1 , slightly more than half as wide, rather coarsely serrate, 5,7 , and 9 feebly or not at all elevated, 5 and 7 each with two or three denticles, 9 either unarmed or with one or two denticles at base of declivity only.

Male.- Similar to female except frons differing as in blaisdelli.

Distribution.- Alberta to Utah and Colorado.

CANADA: Alberta: Banff, IX-1916, white spruce, N. B. Sanson. USA: Colorado: 40 miles ( 64 km ) SW Del Norte, 25-VI-61, $3100 \mathrm{~m}, ~ P$. engelmannii, W. G. Harwood; Gould, 12-VI-68, P. engelmannii, S. L. Wood. Oregon: Dixie Pass, 23-VI-61, Picea engelmannii, S. L. Wood. Utah: Beaver, 10-X1-49, P. engelmannii. S. L. Wood; Logan Dry Canyon, 24-VII-46, 30-V-47, 11-VI-49, P. engelmannii, S. L. Wood; Monte Cristo, 20-VII-49, P. engelmannii, S. L. Wood; McKee Draw, Ashley N.F., I6-VI-60, P. pungens, S. L. Wood. Wyoming: Yellowstone N.P.

Hosts.- Picea engelmannii, P. glauca, and P. pungens.

Brology.- This species breeds in the bole of unthrifty, suppressed seedlings and in unthrifty shaded out branches of large, living, standing trees.

Notes.- The above treatment was based on the holotypes of sansoni and engelmanni, on 31 paratypes of engelmanni, and on 16 other specimens.

## 10. Carphoborus andersoni Swaine <br> Fig. 109

Carphoborus andersoni Swaine, 1919, Rept. Canadian Arctic Exped. 3:6E (Holotype, female; Sandstone Rapids, Coppermine River, Northwest Territories; Canadian Nat. Coll., 9266)
Diagnosis.- This species is distinguished from sansoni Swaine by the less strongly elevated, more sparsely serrate declivital interstriae 1 , by the more strongly elevated lower half of declivital interstriae 3 , and by the more slender declivital teeth.

Female.- Length $1.8-2.2 \mathrm{~mm}$, 2.4 times as long as wide; color dark brown to black.

Frons, pronotum, and elytral disc as in sansoni except frons often shallowly concave, and interstrial granules on interstriae 3, 5, and 7 extend to base; elytral declivity with interstriae 1 weakly elevated, feebly or not at all serrate, 2 very narrow, flat, 3 steadily increasing in height from base to junction with 9 , as high as wide at highest point, armed by 6 to 10 coarse, rather slender teeth.

Male.- Similar to female but sexes differing about as in blaisdelli Swaine.

Distribution.-Alaska to Northwest Territories.

ALASKA: Ft. Yukon, Salmon River. CANADA: Northwest Territories: Aklavik, 20-IX-30, 10-V, 8-VI, 18-V1-31,

Fig. 109. Carphoborus spp., elytral declivities, dorsal and causal aspects: 20, 21, radiatae; 22, 23, ponderosae; 24. 25, carri; 26, 27, sansoni: 28, 29, andersoni; 30, 31, dumni. (After Wood 1954:519.)

28-VII-32, O. Bryant; Sandstone Rapids on Coppermine River, 15-II-15, Picea canadensis, F. Johansen. Yukon: Long. 142, Lat. 65, 21-VII-55, Picea glauca, W. McCambridge.

Host. - Picea glauca.
Biology.-Specimens were reared from spruce branches.

Notes. - The above treatment was based on the holotype and on 59 other specimens.

Fossilized remains of this species were taken in prehistoric lake deposits estimated to be 10,000 to 70,000 years of age in Ontario, Minnesota, and New York.

## 11. Carphoborus dunni Swaine Fig. 109

Carphoborus duni Swaine, 1924, Canadian Ent. 56:235 (Holotype, female, Nictor Lake, New Brumswick; Canadian Nat. Coll., 821)
Diagnosis.- This species is allied to andersoni Swaine and sansoni Swaine, but it is distinguished by the granulate female frons, with shorter pubescence, by the higher, wider declivital interstriae 3 , with denticles on 3 smaller, more abundant, and confused.

Female.- Length $1.6-1.9 \mathrm{~mm}, 2.4$ times as long as wide; color dark brown.

Frons convex, transversely impressed above epistoma; surface granulate-punctate; vestiture short, sparse. Antennal club 1.4 times as long as wide, sutures straight. Pronotum essentially as in blaisdelli Swaine, with scales more slender.

Elytral dise as in sansoni; declivital interstriae 1 weakly elevated, finely serrate, 2 very narrow, flat, 3 very strongly, rather broadly elevated, with denticles confused, not confined to summit, 5 and 7 finely serrate, weakly elevated, joining apically, this elevation usually continuing to 3,9 weakly if at all convex, usually devoid of teeth posterior to declivital base.

Male. - Similar to female except frons differing as in blaisdelli.

Distribution. - Michigan to New Brunswick.

CANADA: New Brunswick: Nictor Lake, 8-VII-21, red spruce, M. B. Dunn. USA: Michigan: Peach Mt., Washtena Co., XI-1977, Larix laricina, L. Kirkendall.

Hosts.-Larix laricina, Picea rubens.
Notes.- The above treatment was based on the type series of 5 specimens and on 21 other specimens.

## 12. Carphoborus radiatae Swaine

 Fig. 109Carphoborus radiatae Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tecl. Bull. 14(2):57 (Holotype, female; Carmel, California; Canadian Nat. Coll., 9430)

Diagnosis.- This species is distinguished from ponderosae Swaine by the shallowly concave female frons, by the less strongly elevated declivital interstriae, and by the slightly less numerous, smaller, declivital teeth.

Female.- Length 1.8-2.4 mm, 2.4 times as long as wide; color dark brown to black.

Frons moderately concave on central three-fourths, surface closely, deeply, rather coarsely punctured; vestiture rather coarse, abundant, moderately long, uniformly distributed except glabrous on a small central area. Antennal club 1.5 times as long as wide; sutures straight.

Pronotum and elytral disc essentially as in blaisdelli Swaine; elytral declivity with interstriae 1,5 , and 7 moderately elevated toward their apices, 5 and 7 joining apically; 2 very narrow to almost obsolete on lower half, flat; 3 and 9 rather strongly elevated, almost as high as wide, joining apically, elevation and its denticles continuing to apex of 1 , serrations moderately coarse, rather close.

Male.-Similar to female except frons differing about as in blaisdelli, frontal impression stronger, elevation stronger and not bituberculate.

Distribution.- Carmel, California.
Specimens were taken at the type locality on various dates from 6-II-13 to VII-19, Pinus radiata, mostly by E. C. Van Dyke and L. S. Slevin.

Biology.-Evidently they breed in unthrifty branches of living trees.

Notes.- The above treatment was based on the holotype and on 49 other specimens.

## 13. Carphoborus ponderosae Swaine Figs. 107, 109

Carphoborus ponderosae Swaine, 1924, Canadian Ent. 56:236 (Holotype, female; Midday Valley, Merritt, British Columbia; Canadian Nat. Coll., 823)
Diagnosis.- This species is distinguished from radiatae Swaine by the flattened female frons, and by the much more strongly elevated, more coarsely, closely serrate declivital interstriae.

Female.- Length $1.8-2.1 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to black.

Frons flattened, elevated toward epistoma; surface finely, rather closely punctured; vestiture of long, rather abundant, uniformly distributed, coarse, subplumose setae.

Pronotum and elytral disc essentially as in blaisdelli Swaine, interstriae narrower than striae, odd-numbered interstriae tending to be uniseriately granulate toward declivity. Declivity not as steep as in other species; interstriae 1 weakly elevated, rather coarsely serrate, 2 very narrow to obsolete, flat, 3 very strongly elevated, higher than wide, coarsely, closely serrate, 5, 7, and 9 moderately elevated, coarsely serrate, 3 and 9 joining apically and continuing as a coarsely serrate, strongly elevated crest to apex of 1 .

Male.-Similar to female except frons differing as in blaisdelli; frontal impression and transverse frontal elevation much more poorly developed than in other species.

Distribution.- British Columbia and Montana to California and Utah.

CANADA: British Columbia: Aspen Grove; Grand Forks, 2-V11-72, Pinus ponderosa, D. E. Bright; Merritt, Midday Valley, 24-V1-23, 17110 lot I157, R. Hopping. USA: California: Hat Creek, 24-V1-61, P. ponderosa, S. L. Wood. Montana: Bozeman; Clinton, 27-IX-36, P. ponderosa, T. O. Thatcher: Rocky Boy Indian Reservation, Hill Co., 25-1X-67, P. ponderosa, D. E. Bright. Oregon: Ft. Rock. Utah: Elk Park, Ashley N.F., I6-V1-60, P. ponderosa, S. L. Wood; 10 miles ( 16 km ) E Kamas, $9-\mathrm{IX}$ 60, P. ponderosa, S. L. Wood; Logan Canyon, 13-VI-46, I4-VI-47, P. contorta, S. L. Wood; La Sal Mts., 5-VII-48, P. ponderosa, S. L. Wood; Pin Hollow, Fish Lake N.F., 9-VI-60, P. ponderosa, S. L. Wood.

Hosts.- Pinus contorta, P. ponderosa.
Brology.- This species breeds in the unthrifty branches of living trees.

Notes.- The above treatment was based on the holotype and on 239 other specimens.
14. Carphoborus declivis Wood

Fig. 108
Carphoborus dechivis Wood, 1954, Canadian Ent. 86:522 (Holotype, female; Lake Tenaya, Yosemite N.P.. California; U.S. Nat. Mus.)
Diagnosis.- This species is distinguished from all other American Carphoborus by the finely serrate declivital interstriae 2.

Female.- Length $1.7-2.0 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to black.

Frons weakly convex, a narrow, transverse impression above epistoma; surface rather
coarsely, deeply, very closely punctured; vestiture of dense, very fine, moderately long hair. Antennal club 1.4 times as long as wide.

Pronotum and elytral disc essentially as in blaisdelli Swaine; elytral declivity with interstriae 1 feebly convex near apex, 1 and 2 equal in width and equally serrate, denticles on 2 less abundant, 3 moderately elevated, about half as high as wide, 5,7 , and 9 weakly elevated, 3-9 serrate, denticles on 4,6 , and 8 slightly smaller, less abundant.

Male.- Similar to female except frons differing as in blaisdelli.

Distribution.- California.
USA: California: Lake Tenaya, Yosemite N.P., II-V111-18, Hopk. U.S. 15740 a and b, Pinus contorta, J. E. Patterson; 10 miles ( 16 km ) N Westgard Pass, Inyo Co., 6-IX-68, P. aristata, D. E. Bright.

## Host.- Pinus contorta.

Notes. - The above treatment was based on the type series of six specimens and on seven other specimens.

## 15. Carphoborus pseudotsugae Wood Fig. 108

Carphoborus pseudotsugae Wood, 1954, Canadian Ent. 86:522 (Holotype, male; Prescott N.F., Arizona; U.S. Nat. Mus.)

Diagnosis.- This species is distinguished from declivis Wood by the rather strongly protruding female frons and by the narrow declivital interstriae 2, which lacks denticles.

Female.- Length $2.1 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to black.

Frons rather strongly convex, narrowly, transversely impressed just above epistoma; surface rather finely granulate-punctate; vestiture evidently short, fine. Antennal club 1.3 times as long as wide.

Pronotum and elytral disc essentially as on blaisdelli Swaine; elytral declivity with interstriae 2 very narrow to obsolete, flat, 3 moderately elevated, 1 and 3 to 9 serrate, denticles on 3 slightly larger and more numerous.

Male. - Similar to female except frons differing as in blaisdelli.

Distribution.- N Arizona.
USA: Arizona: Prescott N.F., 29-V11-30, Hopk. U.S. 20412E, Pseudotsuga taxifolia, M. W. Blackman.

Host.-Pseudotsuga menziesii.
Notes.- The above treatment was based on the holotype and allotype.
16. Carphoborus intermedius Wood Fig. 108

Carphoborus internedius Wood, 1954, Canadian Ent. 86:523 (Holotype, male; New Castle, Colorado: U.S. Nat. Mus.)

Diagnosis.- This species is distinguished from pseudotsugae Wood by the more strongly elevated interstriae 3 , and by the flattened to shallowly impressed female frons with much longer frontal vestiture.

Female.- Length $1.9-2.1 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to black.

Frons flattened to well above eyes, sometimes shallowly concave just above epistoma; surface smooth, densely, finely, deeply, uniformly punctured; vestiture of moderately abundant, fine, long hair, longest setae equal to more than two-thirds length of scape. Antennal club 1.3 times as long as wide.

Pronotum and elytral disc essentially as in blaisdelli Swaine, with striae slightly wider than interstriae, interstriae 1 and 3 with a few indistinct granules; elytral declivity not as steep as in most species, 1 weakly, 3 and 9 strongly elevated, almost as high as wide, 3 and 9 joining apically, 1 and 3 to 9 finely serrate, denticles on 3 and 9 slightly larger, more numerous.

Male. - Similar to female except frons differing as in blaisdelli, though transverse impression not as deep or abrupt, and median elevation reduced, sometimes almost entirely absent.

Distribution.-Alaska to Oregon and Colorado.

ALASKA: Bonanza Creek, 20 miles W Fairbanks, 12-VII-77, pheromone trap, T. Ward. USA: Colorado: New Castle, Hopk. U.S. 31408-2-4, Picea engelmannii, C. L. Massey; Grand Lake, 5-X-38, Hopk. U.S. 31542-J2, Pinus contorta. Oregon: Tolgate, 1 to $15-\mathrm{V} 11-50$, on aluminum roof. E. S. McClusky. Washington: Metaline Falls, 15-V11-32, Hopk. U.S. 22366, flight, T. T. Terrell.

Hosts.- Picea engelmannii and Pinus contorta.

Notes. - The above treatment was based on eight paratypes and on five other specimens.

## 17. Carphoborus perplexus Wood

Carphoborus perplexus Wood, 1960, Great Basin Nat. 20:59 (Holotype, female; 10 miles or 16 km E Kamas, Utah; Wood Coll.)
Diagnosis.- This species closely resembles sansoni Swaine, but it is distinguished by the
more strongly elevated, serrate, declivital interstriae 9 , by the higher declivital interstriae 3 , which does not curve toward 1 at its apex as does sansoni, and by the more broadly flattened female frons.

Female.- Length $1.8-2.2 \mathrm{~mm}, 2.4$ times as long as wide; color dark brown to black.

Frons flattened on median two-thirds from epistoma to well above eyes, epistomal margin distinctly raised, premandibular lobe large; surface shining, finely, closely punctured: vestiture of rather short, moderately abundant, subplumose setae. Antennal club 1.3 times as long as wide.

Pronotum and elytral disc essentially as in blaisdelli Swaine, except interstriae 3 with a row of granules to base, 5 and 7 with granules on posterior third; elytral declivity with interstriae 1, 3, and 9 moderately elevated, 3 and 9 joining apically but not continuing toward apex of 1 ; interstriae $1,3,5,7$, and 9 serrate, denticles averaging smaller than in sansoni.

Male.- Similar to female except frons differing essentially as in blaisdelli but contours less abrupt.
Distribution.-Utah.
USA: Utah: 10 miles ( 16 km ) E Kamas, 9-IX-60, 13-VII-62, Pinus ponderosa, S. L. Wood.

Host.- Pinus ponderosa.
Biology.- This species breeds in the unthrifty lower branches of the living host.

Notes.- The above treatment was based on the type series of 40 specimens and on 19 other specimens.

## 18. Carphoborus piceae Wood

Carphoborus picete Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):11 (Holotype, male; Dixie Pass, Oregon; Wood Coll.)
Diagnosis.- This species is distinguished from perplexus Wood by the absence of granules on discal interstriae 3, by the less strongly elevated alternate declivital interstriae, with smaller denticles, and by the more narrowly flattened female frons.

Female.- Length $1.7 \mathrm{~mm}, 2.2$ times as long as wide; color almost black.

Frons flattened on little more than median half from epistoma to very slightly above eyes, epistomal margin distinctly elevated; surface subrugulose, rather finely, closely
punctured; vestiture of rather abundant, moderately long, coarse, subphimose setae.

Pronotum and elytral dise as in perplexus except interstriae 3 devoid of granules; elytral declivity as in perplexus except interstriae 1,3 , and 9 less strongly elevated, with denticles smaller, 2 wider.

Male. - Similar to female except frons differing as in perplexus.

Distribution.- Oregon.
USA: Oregon: Dixie Pass, Malheur N.F., 23-V1-61. Picea engelmannii, S. L. Wood.

Host.-Picea engelmannii.
Biology.- This species was taken from an unthrifty branch of a very recently fallen tree.

Notes.- The above treatment was based on the type series of three specimens.

## 19. Carphoboras carri Swaine

Fig. 109
Carphoborus arri Swaine, 1917. Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):16 (Holotype. male: Edmonton, Alberta: Canadian Nat. Coll. (9267)

Diagnosis.- This species is distinguished from bifurcus Eichhoff by the less strongly elevated declivital interstriae 3, by the fusion of declivital interstriae 3 and 5 , and by the flattened, finely punctured female frons, with much longer vestiture.

Female.- Length $1.4-2.1 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to almost black.

Frons flattened on median two-thirds from epistoma to slightly above eves; epistomal margin slightly elevated; surface shining, closely, deeply, finely punctured; vestiture of rather fine, long, moderately abundant, subphumose setae. Antennal club 1.3 times as long as wide.

Pronotum about as in blaisdelli Swaine except punctures much smaller. Elytra with striae distinctly impressed, punctures very coarse, moderately deep; interstriae narrower than striae, surface irregularly granulatepunctate. Declivity convex, rather steep; interstriae 1 moderately elevated, serrate, 2 flat, narrow above, obsolete below, 3 strongly elevated, as high as wide, serrate, 5,7 , and 9 moderately elevated and serrate; denticles on all armed interstriae very small; interstriae 3 and 9 fuse at apices, 5 and 7 also fuse at
apices. Pronotal and elytral scales broader and apparently more abundant than in other species.

Male. - Similar to female except frons much as in blaisdelli, with transverse impression shallow, transverse elevation obsolete.

Distribution.-Alaska and Northwest Territories to Wyoming and New Brunswick.

ALASKA: Fairbanks. CANADA: Alberta, Manitoba, New Brunswick. Northwest Territories, Yukon. US.A: Montana, South Dakota. Wyming.

Hosts.- Picea engelmannii, P. glauca, $P$. rubens.

Biology.-This species evidently prefers to breed in the bole of standing suppressed trees up to 8 inches ( 20 cm ) in diameter, although it is commonly found in the unthrifty, lower branches of living trees.

Notes.- The above treatment was based on the holotype and on 316 other specimens.

## 20. Carphoborus bifurcus Eichhoff Fis. IOT:

Carphoborus bifurcus Eichhoff, 1865. Berliner Ent. Zeitschr. 12:147 (Syntypes; "Am. bor.": presumably destroved with Hamburg Mus.)
Carphoborns bicristatus Chapuis, 1869, Synopsis des Scolytides, p. 41 (Syntypes; Carolina: Brussel Mus.): Wood, 1954, Canadian Ent. 86:525. Synomymy
Diagnosis.- This species is distinguished from carri Swaine by the convex, densely punctate to finely granulate female frons. with much shorter, finer vestiture, by the much more strongly elevated declivital interstriae 3 , and by declivital interstriae 5 and 7 ending separately at their apices.

Female.- Length $1.4-1.8 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown.

Frons convex, surface densely, minutely punctured to densely, finely granulatepunctate to well above eves; vestiture very fine, moderately abundant, rather short. Antemal club 1.3 times as long as wide.

Pronotum much as in other species except lateral constriction near anterior margin almost obsolete, and surface coarsely, very closely, rather deeply punctured.

Elytral striae not impressed, punctures coarse, deep; interstriae narrower than striae, irregular, granulate-punctate. Declivital interstriae 1 weakly elevated, feebly serrate, 2
narrowed, almost flat, 3 very strongly elevated, much higher than wide, fusing with apex of 9 and continuing to apex of 1,5 and 7 weakly elevated, each with two or three denticles, 9 moderately elevated toward apex, with a few, fine serrations. Vestiture much as in carri.

Male.- Similar to female except frons more nearly granulate, a slight transverse impression above epistoma and a small, transverse, median elevation at upper level of eyes; vestiture coarse, short.

Distribution. - Missouri and New York to Mississippi and Florida.
USA: District of Columbia, Florida, Georgia, Maryland, Mississippi, Missouri, New York, North Carolina, Tennessee, Virginia, West Virginia.

Hosts.-Pinus clausa, $P$. echinata, $P$. taeda, and P. virginiana.

Biology.- Apparently only small branches are attacked in slash or unthrifty branches of living trees.

Notes.- The above treatment was based on 191 specimens. The holotype of bifurcus evidently is lost, but this species is easily identified from Eichhoff's descriptions.

Three females from Fayette, Alabama, taken in pine in May 1959, exhibit a consistent, radical aberration of the frons; the one male is normal. These females have the frons much less convex than normal, the surface is finely rugose-reticulate, punctures are absent; just below the upper level of the eyes is a pair of widely spaced, strongly procurved, conical, hornlike spines, each twice as high as wide, equal in length to the width of the antennal club; except for a few fine scales, the frontal vestiture is absent. Except for the frons, these specimens are normal representatives of bifurcus. Because the locality from which they come is neither peripheral nor isolated from the distribution of this species, they probably are nothing more than mutant curiosities.

Genus POLYGRAPHUS Erichson

Polygraphus Erichson, 1836, Archiv Naturgesch. 2(1):57
(Type-species: Hylesinus pubescens Fabricius $=$ Dermestes poligraphus Linnaeus, monobasic)
Lepisomus Kirby, 1837, in Richardson, Fauna BorealiAmericana 4:193 (Type-species: Apate (Lepisomus) rufipennis Kirby, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:124); Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):55. Synonymy

Pseudopolygraphus Seitner, 1911, Centralbl. Ges. Forstw. 37(3):105 (Type-species: Polygraphus grandiclava Thomson, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:128); Hopkins, 1915, U.S. Dept. Agric. Tech. Bull. 17(2):222. Synonymy
Ozophagus Eggers, 1919, Ent. Blätt. 15:234 (Typespecies: Ozophagus camerunus Eggers, present designation); Schedl, 1950, Bull. Inst. Roy. Sci. Nat. Belg. 26(50):2. Synonymy
Diagnosis. - The only closely allied American genus is Carphoborus Eichhoff. This genus is distinguished from Carphoborus by the completely divided eye (some African and Asian species have the eye very deeply emarginate), by the aseptate antennal club without indications of sutures, and by the much more conservative sculpture of the elytra.

Description.- Length $1.8-3.1 \mathrm{~mm}$, 2.0-2.4 times as long as wide; mature color almost black, vestiture pale. Frons dimorphic; male impressed on lower half above epistoma and below summit, convex above, summit just above center usually armed by a pair of small tubercles; female convex, flat, or impressed, finely punctured and variously ornamented by fine hair. Eye completely divided by an emargination into dorsal and ventral halves, a few facets sometimes scattered between them along posterior margin. Antennal scape rather long, attaining posterior margin of eye; funicle either 5 - or 6 -segmented; club rather asymmetrical, moderately flattened, aseptate, very finely, uniformly pubescent, without indications of sutures. Pronotum unarmed, smooth, with close, fine punctures. Scutellum absent; basal margins of elytra armed by 11 or 12 rather coarse crenulations, submarginal crenulations sometimes present on interstriae 2 to 4 ; striae not impressed, punctures fine; interstriae densely punctured; declivity broadly convex, very conservatively sculptured. Third tarsal segments narrow. Vestiture of abundant small scales.

Distribution.-Alaska, Canada, and the northern and mountainous parts of the United States where spruce forests grow; Europe, Asia, and Africa. About 60 species are known; three of these occur in North America.

Biology.- Recently broken, cut, or fallen trees are normally selected for attack, although these moderately aggressive beetles
readily attack unthrifty trees or those weakened by the primary invasion of other bark beetles. These prolific beetles are polygynous. Either the male or female may construct the entrance tunnel and nuptial chamber in the phloem tissues (Rudinsky, Oester, and Ryker 1978). Normally the female is joined by a male, he then admits three to five or more females, each of which constructs an egg gallery that radiates from the central nuptial chamber. In most areas the egg tunnels follow any direction or curve to avoid other galleries or obstacles. In eastern Canada the egg galleries of rufipennis (Kirby) have a definite tendency to curve transversely across the grain of the wood. Egg galleries usually reach the cambium, but normally do not score the wood; they may also be entirely in the phloem and do not show on peeled bark. These variations may occur in any one gallery system. Eggs are
deposited in large, individual niches along the margins of the egg tunnels. The larval mines are usually entirely in the phloem and may or may not score the wood. When oviposition is complete, parent adults normally abandon their galleries and produce a second, third, or more broods elsewhere on the same or another host. Two or more overlapping generations can be produced each year where climatic factors are favorable.

Notes.- In addition to the synonyms of this genus listed above, Schedl (1960:359) also considered Spongotarsus Hagedorn, from the East Indies, to be a synonym. Ozophagus camerunus Eggers is here designated as the type species of the genus Ozophagus because all type material of the other original species, militaris, is lost.

## Key to the Species of Polygraphus

1. Body stouter, less than 2.2 times as long as wide; apex of antennal club more obtusely pointed; female frons less densely punctured in central area, interspaces there mostly equal in width to diameter of a puncture; Alaska and Arizona to Newfoundland and North Carolina; Picea; 1.8-3.1 mm
2. rufipennis (Kirby)

- Body more slender, at least 2.3 times as long as wide; antennal club strongly acuminate at apex; female frons densely punctured in central area, interspaces there rarely half as wide as diameter of a puncture .2
2(1). Female frons shallowly concave, at least longitudinally, from epistoma to vertex; female frontal vestiture rather abundant, moderately long, longest setae above upper level of eyes longer than distance equal to greatest width of eye; N Arizona; Picea engelmannii; 2.3-2.9 mm

2. hoppingi Swaine

- Female frons convex or rarely flattened on lower half; female frons commonly glabrous, longest setae rarely as much as half as long as greatest width of eye; Alaska to Utah and New Mexico; Picea engelmannii, P. glauca; 2.4-2.9 mm ......

3. convexifrons Wood

## 1. Polygraphus rufipennis (Kirby) Figs. 110, 111

Apate (Lepisomus) rufipennis Kirby, 1837, in Richardson, Fauna Boreali-Americana 4:193 (Syntypes; Boreal America. Lat. $65^{\circ}$; British Mus. Nat. Hist.)
Apate (Lepisomus) nigriecps Kirby, 1837, in Richardson, Fauna Boreali-Americana 4:194 (Holotype, male; Boreal America, Lat. $65^{\circ}$; British Mus. Nat. Hist.); LeConte, 1868, Trans. Amer. Ent. Soc. 2:169. Synonymy
Apate (Lepisomus) brecicornis Kirby, 1837, in Richardson, Fauna Boreali-Americana 4:19.4 (Holotype, female; Boreal America, Lat. $65^{\circ}$; British Mus.

Nat. Hist.); LeConte, 1868, Trans. Amer. Ent. Soc. 2:169. Synonymy
Polygraphus saginatus Mannerheim, 1853, Bull. Soc. lmp. Nat. Moscou 26 (pt. 2, no. 3):237 (Holotype, female; Kenai Peninsula, Alaska: Helsinki Mus.); LeConte, 1868, Trans. Amer. Ent. Soc. 2:169. Synonymy
Diagnosis.- This species has been treated as a synonym of poligraphus (Linnaeus), of Europe and northern Asia, by Schedl (1957:150). Although occasional specimens are indistinguishable, the overwhelming majority are clearly separable. This species is
distinguished from poligraphus by the more coarsely punctured frons, pronotum, and elytra, by the more clearly, coarsely granulose punctures near the lateral margins of the pronotum, and by the more numerous, coarser elytral tubercles, particularly toward the base.

Female.- Length $1.8-3.1 \mathrm{~mm}, 2.0-2.2$ times as long as wide; color very dark brown to black, vestiture usually pale.

Frons transversely impressed above epistoma, somewhat flattened to upper level of eyes, convex above; epistoma slightly elevated, shining; surface deeply, rather coarsely
punctured, punctures very close except in central area, interspaces mostly as wide as punctures; vestiture of fine, rather short hair, longest about equal to half greatest width of eye. Apex of antennal club blunt, about equal to a 90 degree angle.

Pronotum 0.70 times as long as wide; widest at base, sides almost straight and converging anteriorly on basal two-thirds, rather strongly constricted just before anterior margin; surface shining, indications of reticulation evident particularly on anterior third, punctures deep, close, fine to moderately coarse intermixed, their lateral margins

Fig. 110. Polygraphus spp., antennae and tibiae: 6, 9, rufipennis; 7, 10, hoppingi; 8, 11, convexifrons. (After Hilton 1968:27.)
elevated and sometimes granulate in lateral areas; vestiture of rather abundant, suberect scales, each scale about six times as long as wide.

Elytra 1.5 times as long as wide, 2.2 times as long as pronotum; basal margins each armed by 12 rather coarse crenulations from suture to humeral angles, submarginal crenulations rather abundant medially, a few extending to humeral angles; sides almost straight and parallel on basal three-fourths, broadly rounded behind; strial and interstrial punctures confused, moderately small, rather shallow, close; interstriae indicated by rows of granules, uniseriate on and near declivity, moderately confused on central part of disc, strongly confused and crenulate toward base in median area. Declivity rather steep, convex; about as on disc. Vestiture of abundant small scales in ground cover, each scale about two to three times as long as wide; and interstrial rows of slightly longer scales often visible only on declivity.

Male. - Similar to female except frons with a bituberculate, median elevation at upper level of eyes, more strongly impressed below and more convex above this point, vestiture largely obsolete; elytral tubercles perhaps very slightly larger.

Distribution.- Alaska and New Mexico to Newfoundland and North Carolina.

ALASKA: Numerous localities. CANADA: All provinces. USA: Arizona, Colorado, District of Columbia, ldaho, Maine, Massachusetts, Michigan, Minnesota, Montana, New Hampshire. New Mexico, New York. North Carolina, North Dakota. Oregon, Pennsylvania, South Dakota, Tennessee, Utah, Vermont, West Virginia, Wisconsin, Wyoming.

Hosts.-Picea engelmannii, P. glauca, $P$. pungens, P. rubra, Abies fraseri, Pinus strobus.

Biology.- The winter is passed in any stage except the egg. According to Simpson (1929:146-151), the female constructs an entrance tumnel and nuptial chamber; she is then joined by a male; later he admits two or more additional females. I suspect Simpson observed previously mated adults and I would expect newly emerged, unmated males to initiate the attack. (This supposition was confirmed by Rudinsky et al. 1978.) Previously mated females under stress may excavate galleries and develop a brood without a
male. Simpson stated that adults may produce as many as four sets of tumnels with brood in a season. Brood from the first tunnels complete development but hibernate as young adults in the brood chambers; from the second tunnels they hibernate as young adults and mature larvae; from the third and fourth tunnels they hibernate as larvae in various stages of growth. The successive sets of galleries are formed at about monthly intervals beginning in mid-June.

Notes. - The types of rufipennis, nigriceps, and brevicornis were all examined. Only one female specimen of saginatus, without a locality label, is in the Mannerheim Collection at the present time, but it is considered to be sufficiently authentic to remove doubt as to the identity of Mannerheim's species; it could actually be the type of saginatus. All these specimens clearly belong to the same species and are consistent with my North American material, although direct comparisons were not made. The above treatment was based primarily on my series from Patagonia Springs, Colorado, and on more than 3000 other specimens.

Fig. 111. Polygraphus spp. heads: 15, 16, rufipennis, male; 17. 18, rufipennis, female; 19, hoppingi, male; 20. hoppingi. female; 21, convexifrons, male; 22 , convexifrons, female. (After Hilton 1968:27.)

As indicated in the above diagnosis, the status of this species was questioned by Schedl without citing either characters or the origin or extent of material he studied. It is abundantly clear to me that this species is separable from poligraphus on a statistical base involving a comparison of the pronotal punctures (twice or more as large in most rufipennis) or of tubercles at the bases of the elytra (larger, more numerous, and extending to or lateral to the humeral bulla in rufipennis). Of the material used in this comparison, 144 of the 201 rufipennis were from Alaska and the Northwest Territories and 16 of the 60 poligraphus were from Japan and Siberia.

## 2. Polygraphus hoppingi Swaine Figs. 110, 111

Polygraphus hoppingi Swaine, 1925, Canadian Ent. 57:51 (Holotype, female; San Francisco Peak, Coconino Co., Arizona; Canadian Nat. Coll., 1329)

Diagnosis.- This species is distinguished from the very closely related convexifrons Wood by the shallowly concave female frons, which is ornamented by rather long, yellow hair, and by the distribution.

Female. - Length $2.3-2.9 \mathrm{~mm}, 2.4$ times as long as wide; color almost black, vestiture lighter.

Frons impressed above epistoma, becoming shallowly concave between eyes in most specimens (flat in some), some impression usually extending to vertex; surface shining, densely, finely, deeply punctured, interspaces averaging much less than half width of a puncture; vestiture very fine, rather abundant, long, longest setae equal to one and one-half times greatest width of eye. Tip of antennal club narrowly acuminate.

Pronotum 0.76 times as long as wide; outline as in rufipennis except sides weakly arcuate; surface brightly shining, smooth, punctures fine, moderately deep, interspaces averaging slightly larger to twice diameter of a puncture, not granulate laterally; vestiture of small, erect, scales, each scale four to six times as long as wide.

Elytra 1.7 times as long as wide, 2.1 times as long as pronotum; basal margins each armed by 11 crenulations, fewer submarginal crenulations than in rufipennis; outline as in
rufipennis; strial and interstrial punctures confused, small, shallow, close; interstriae indicated by uniseriate rows of fine granules. Declivity rather steep, broadly convex; sutural interstriae weakly elevated, 2 slightly impressed, sculpture as on disc.

Male.-Similar to female except frons as in male rufipennis, but more finely, closely punctured; declivity slightly more strongly impressed, granules on interstriae almost obsolete; body very slightly stouter.

Distribution.- N Arizona.
USA: Arizona: North Rim Grand Canyon, 24-IX-49, Picea engelmannii, S. L. Wood; San Francisco Peak; 20-VI-18, Picea engelmamii. R. Hopping.

Host.- Picea engelmannii.
Biology.- The habits evidently are about as in rufipennis.

Notes.- The above treatment was based on the holotype, on 6 topotypes, and on 49 specimens from the north rim of the Grand Canyon.

Although intermediates in the usual sense have not been seen, I suspect that hoppingi and convexifrons are subspecies of one another. However, available specimens from adjacent parts of their known distributions are distinct, with no suggestion of intergradation.

## 3. Polygraphus convexifrons Wood Figs. 110, 111

Polygraphus convexifrons Wood, 1951, J. Kansas Ent. Soc. 24:32 (Holotype, female; Logran Dry Canyon, Cache Co., Utah; U.S. Nat. Mus.)
Diagnosis.- This species is distinguished from the very closely related hoppingi Swaine by the rather strongly convex female frons, by the shorter or even totally obsolete female frontal pubescence, and by the more distinctly impressed male elytral declivity, with granules on interstriae 2 smaller or obsolete.

Female.- Length 2.4-2.9 mm, 2.5 times as long as wide; color very dark brown, almost black, vestiture lighter.

Frons slightly protuberant above epistoma, moderately to strongly convex to vertex; surface shining, densely, finely, deeply punctured, interspaces less than half as wide as a puncture; vestiture very fine, varying in specimens from absent to very finely pubescent, longest hairs equal to about half greatest width of eye. Antennal club as in hoppingi.

Pronotum 0.76 times as long as wide; as in hoppingi except punctures averaging very slightly larger in southern parts of range.

Elytra 1.7 times as long as wide, 2.0 times as long as pronotum; essentially as in hoppingi.

Male.- As in male of hoppingi except elytral declivity slightly more strongly impressed; granules on interstriae reduced in size, partly or entirely obsolete.

Distribution.- Alaska to Utah and New Mexico.

AlaSka: Matanuska, 27 -VIII-45, flight, J. C. Chamberlin: McKinley N.P., 6-III-42. Hopk. U.S. 33676, Pieea canadensis, F. Bean, 6-VI-48, P. canadensis. J. S. Stanford. CANADA: Alberta: Ilighwood Pass 40 miles S Exshaw, 8-1N-67, P. engelmannii, D. E. Bright. Yukon: Dawson City. 10-VII-68. Campbell and Smitana: 21 mile carmark, Mayo Road, 7-VII-60, P. glauca. USA: Colorado: Del Norte, 25-V1-68, P. engelmannii, W. G. Harwood; Gould, 12-VI-68, P. engelmannii, S. L. Wood; Mt. Evans, II-VII-6I, J. R. Stainer; Los Pinos Pass, Saguache Co.. 24-V1-68, P. engelmamii, W. G. Harwood; Pitkin,

I6-X-I5. New Mexico: New Mexico, F. H. Snow. South Dakota: Harnev. Utah: Beaver Canvon, Beaver Co., I5-IX-49, P. engelmannii. S. L. Wood: Escalante, Dixie N.F., 26-VIII-56. P. engelmannii, M. D. McGregor; La Sal Mts., 5-VII-5S, P. engelmannii, S. L. Wood; Logan Dry Canyon, 6-VII-48, P. engelmannii, S. L. Wood; Puffer Lake, Beaver Co., 17-IX-49, P. engelmannii, S. L. Wood.

Hosts.- Picea engelmannii, and P. glauca.
Biology. - The habits evidently are very similar to rufipennis. When this species was taken in competition with rufipennis, the egg galleries always passed above (toward the outer bark) those of rufipennis, and the brood almost never completed development. The egg galleries normally are at or near the cambium. This is a rare species that is seldom found in disturbed areas.

Notes. - The above treatment was based on the holotype, on 6 paratypes, and on 62 other specimens.

## Subfamily SCOLYTINAE

Scolytaria Latreille, 1807, Genera Crustaceorum et Insectorum 2:273.

Previous classifications have recognized the tribe Scolytini as a subfamily distinct from the previously recognized Ipinae on the basis of the Scolytus-like tibiae that lack supernumerary serrations or socketed teeth and the ascending venter of the abdomen, which rises to meet the elytral apex. In the Cncmo$n y x$ the tibial character applies only to the protoracic leg, and the abdominal character is of dubious value because it occurs in various genera of several tribes. The protibia of the Ctenophorini approaches that of the Scolytini so closely that I find it impossible to continue the recognition of separate subfamilies for these taxa.

Anatomical features.- The subfamily Scolytinae is distinguished from the Hylesininae by the absence of crenulations on the elytral bases and by having the elytral bases form an almost straight transverse or slightly recurved line, without a noticeable scutellar notch. In addition, most of the more highly evolved genera have the head concealed by the pronotum when viewed from the dorsal aspect and the anterior slope of the pronotum asperate. The Scolytini and some of
the Ctenophorini usually lack these two characters. A few South American Cnemonyx have primitive crenulations on the basal margins of the elytra, as in the Hylesininae, but this feature in no sense removes them from the tribe Ctenophorini or from the genus Cnemonyx.

Biological features.- Of the 79 genera treated here, 40 are phloeophagus, 4 are xylophagus, 23 xylomycetophagous, 1 is in a transitional stage, and one breeds in cucurbit vines. Some of the genera include species that breed in pith of twigs or other small stems or in seeds.

Taxonomy.- The Scolytinae apparently arose from a primitive curculionoid stock that gave rise to the Platypodidae and to primitive Scolytidae. The Hylesininae evidently arose much later from the Scolytinae.

The North and Central American Scolytinae are here divided into 11 rather distinct tribal groups, the Scolytini, Ctenophorini, Micracini, Cactopinini, Cryphalini, Dryocoetini, Ctenophorini, Ipini, Xyloterini, Xyleborini, and Corthylini, with a majority of the species placed in the last two tribes.

## Tribe SCOLyTini

Scolytari Latreille. 1807, Genera Crustaceorum et Insectorum 2:273 (Type-genus: Scolytus Geoffroy, 1762)
Camptoceridae Chapuis, 1869, Synopsis des Scolytides, p. 49 (Type-genus: Camptocerus Latreille, 1829)
Eccoptogasteridae Trèdl, 1970. Ent. Blatt. 3:4 (Type-genus: Scolytus Geoffroy, 1762 = Eccoptogaster Herlast, 1793)

Anatomical features.-- The frons is strongly, sexually dimorphic, with the male variously impressed, the female flat to convex, one or both often ornamented by hair; the posterior area of the head is subtruncate, the eye is entire, the funicle is 7 -segmented, the pronotum is unarmed, its lateral margins costate, the protibia (usually all three tibiae) is unarmed on the lateral margin with the outer apical angle extended into a spine that curves toward and exceeds the inner apical angle, socketed denticles are never present, and the metpleural suture descends subvertically to the groove, receiving the groove on the costal margin of the elytra, then turns abruptly and parallels the groove to near the metacoxal process. In most species the venter of the abdomen ascends conspicuously to meet the elytra.

Biological features. - All except a few bigamous Neotropical Scolytus are monogamous; all are phloeophagous except Camptocerus, which is xylomycetophagous. The parental galleries are mostly biramous, a few are monoramous, and Camptocerus has a unique extension into the xylem from a biramous tumnel in the cambium. Eggs are deposited in niches. Larval mines of phloeophagous species follow a definite course and rarely cross one another. Camptocerus larvae are reared in short cradles that are somewhat similar to those of other ambrosia beetles.

Taxonomy.- Except for Scolytus, some species of which occur in Eurasia, this tribe is exclusively American. This tribe probably is more nearly like the ancestral group that gave rise to the Hylesininae than any other living representatives of that family. They also appear closely allied to the ancestral line from which the Platypodidae diverged. The four genera assigned to this tribe represent a
compact group in which the genera are not always clearly recognizable, largely because characters of the large, diverse genus Cnemonyx tend to overlap those of the other three.

## Genus CNEMONYX Eichhoff

Cnemonyx Eichhoff, 186s (May), Berliner Ent. Zeitschr. 12:150 (Type-species: Cacmonyx glacritus Eichhoff, monobasic)
Ceratolepis Chapuis, 1869. Synopsis des Scolytides, p. 52) Type-species: Ceratolepis jucundus Chapuis. monobasic): Wood. 1971. Great Basin Nat. 31:140. Synonymy
Loganius Chapuis, is69. Synopsis des Scolytides p. 52 Type-species: Loganius flaticornis Chapuis. monobasic): Wood, 1971. Great Basin Nat. 31:140. Synonymy
Minulus Eggers, 1912. Eat. Btätt. 8:206 (Type-species: Minulus barbatus Eggers, monobasic): Eggers. 1923. Ent. Blatt. 19:138. Synonymy

Diagnosis.- This genus is distinguished from Camptocerus Latreille and Scolytus Geoffroy by the small, rounded scutellum, by the antennal club that normally has up to three sutures indicated, by the more nearly asymmetrical antennal club, and by other characters mentioned in the key to genera.

Description.-Length $1.0-3.9 \mathrm{~mm}$, 2.0-2.7 times as long as wide. Color dark brown to black; vestiture sparse, short, of scales and/or hair.

Frons variable, shallowly concave to convex in female, usually more strongly impressed in male; vestiture varying from absent to an elaborate brush of hair, usually longer or more abundant in male. Antennal funicle 7 -segmented, ventral margin of flagellar segments usually ornamented by small tufts of long setae, more elaborately ornamented in male. Pronotum large, broad, unarmed, lateral margins acutely marked by an elevated line. Scutellum small, flattened to convex, usually longer than wide, its surface
equal in height to elytral surface (not depressed). Elytral bases with a fine, raised line on margin (broken into obscure marginal crenulations in a few species), not emarginate toward scutellum; sculpture fine to moderate; declivity gradual, armature feebly developed if present. Abdomen rather strongly ascending to meet elytra at apex. Tibiae as in Camptocerus and Scolytus except meso- and metathoracic anterior edge of apical margin armed by small teeth in most species.

Distribution.-S Florida and Baja California to Argentina; about 35 species have been named, 20 occur in North and Central America.

Biology.-All species are phloeophagous. They construct simple or biramous parental galleries that normally engrave both bark and wood. Eggs are deposited individually in separate niches along the margins of the egg tunnels. The larvae construct irregular mines mostly in the phloem tissues.

## Key to the Species of Cnemonyx

1. Antennal club without distinct rows of hair marking sutures (two obscure rows in exiguus), hair usually short, often intermixed with scales; anterior edge of apical margin of hind tibia an acute, continuous, unarmed costa

- Antennal club with three sutures clearly marked by rows of long, hairlike setae; hind tibiae armed on anterior edge of apical margin by two or three distinct teeth

2(1). Declivital interstriae narrowly convex, subcarinate; interstriae subglabrous, minute scales when present scarcely project above punctures producing them; male frons broadly, rather deeply concave, uniformly ornamented by rather long, dark hair; male epistomal margin armed on median third by a strongly elevated, slightly procurved, transverse carina; Costa Rica to Columbia and Venezuela; 3.5-3.9 mm ...................................................................... 1. insignis Wood

- Declivital interstriae moderately if at all convex, vestiture if present usually longer; male frons variously ornamented; male carina, if present, very weakly developed or else located at or above level of antennal insertion; smaller species

3(2). Frons slightly if at all dimorphic, moderately concave in both sexes (except maculicornis); frontal carina, if present, feebly developed and on epistomal margin; elytral vestiture, if present, sparse and short, usually not longer than distance equal to diameter of a strial puncture

- Frons strongly dimorphic, females weakly to moderately convex, males concave and with a conspicuous transverse carina at level of antennal insertion or slightly above; elytral vestiture more abundant and much longer

4(3). Striae weakly impressed, punctures moderately large; interstriae almost smooth, punctures small to rather large, confused; frons shallowly concave, punctures small, ornamented by fine, moderately long hair; epistomal margin distinctly elevated throughout its length5

- $\quad$ Striae strongly impressed, interstriae moderately to rather strongly convex and at least partly subcrenulate

5(4). Strial and interstrial punctures larger, confused on at least anterior half of interstriae; female frons with punctures finer, closer, vestiture continued to upper limits of impressed area, this upper area punctured; Costa Rica to Panama; $2.0-2.5 \mathrm{~mm}$
2. atratus (Blandford)

- $\quad$ Strial punctures fine, interstrial punctures very fine, uniseriate; female frons with punctures larger, not as close, vestiture in a pair of lateral tufts, obsolete on rugose area at upper part of impressed area; Chiapas; 2.4 mm

3. glabratus (Schedl)

6(4). Epistoma not separated from margin, epistomal brush below margin, median third above epistoma smooth, impunctate, frontal concavity finely punctured, ornamented by dense, coarse yellow hair; pronotum coarsely, closely punctured on disc, lateral punctures indistinctly larger; interstrial crenulations at base as wide as interstriae on 1-3, narrower behind, continuing to declivity; interstrial setae uniseriate, of short slender bristles; Brazil (not Mexico); 1.7-1.9 mm 4. errans (Blandford)

- Epistoma distinctly elevated above and separate from margin, epistomal brush arising above margin and below epistoma, median third of frons above epistoma subinflated, transversely subrugose and coarsely punctured, frontal concavity reticulate to reticulate-granulate, rather finely (but sometimes appearing coarsely) punctured, vestiture of very fine, moderately long hair; pronotal disc much more finely punctured than in lateral areas; interstrial crenulations small, confused, small and poorly developed on declivity; interstrial setae confused, recumbent, somewhat scalelike; Honduras to Colombia; $1.8-2.3 \mathrm{~mm}$.

5. maculicornis (Blandford)

7(3). Elytral scales confused or indistinctly three-ranked; interstrial punctures fine, confused, many subcrenulate on basal half; female frons feebly convex above, slightly impressed below, minutely granulate; male frons shallowly concave, ornamented above by tufts of yellow hair on each side, a strong, transverse carina at level of antennal insertion on more than median three-fourths, a median tubercle on epistomal margin; Costa Rica to Panama and Venezuela; Vismia; $1.8-2.3 \mathrm{~mm}$
6. panamensis (Blandford)

- Elytral scales in uniseriate interstrial rows, interstrial punctures uniseriate, more or less subvulcanate from base to apex at least in female; transverse frontal carina of male slightly above level of antennal insertion, less acute, median epistomal tubercle absent

8(7). Pronotal surface longitudinally strigose without any indication of reticulation on posterior half, punctures larger, deeper; interstrial punctures much larger, deeper on disc; declivital surface minutely rugulose-punctate; transverse frontal carina of male rather poorly developed, occupying median half, area above carina very shallowly impressed and ornamented by a small, conspicuous pubescent area; Veracruz to Panama; Vismia; 1.6-1.7 mm

- Pronotal surface reticulate to base, punctures smaller, shallow; interstrial punctures finer and more widely spaced on disc; declivital surface reticulate; transverse frontal carina of male more strongly developed, much wider, area above carina strongly, broadly impressed, with sparse vestiture more widely distributed; Costa Rica to Panama; 1.5-1.9 mm ...................... 8. exiguus (Blandford)

9(1). Frons rather conspicuously dimorphic, devoid of a transverse carina in both
sexes, upper area more strongly impressed in males; declivital interstriae tend
to be equally convex ................................................................................................. 10

- Frons indistinctly dimorphic, both sexes with a transverse carina just above epistoma; most species with one or more interstriae elevated or depressed

10(9). Epistomal margin very broadly, rather deeply emarginate; mandibles con-
spicuously, transversely strigose on median half of visible surface; costal mar-
gin near elytral apex entire, not subserrate or tuberculate; S Florida to Virgin
Islands; Ficus; 2.2-2.4 mm ................................................................ 9. ficus (Schwarz)

- Epistomal margin straight or procurved; costal margin of elytra subserrate to $\quad$ tuberculate near apex; mostly smaller species .................................................... 11

11(10). Striae not at all impressed, their punctures fine, spaced by distances at least
equal to twice diameter of a puncture; interstrial punctures equal in size and
spacing to those of striae ........................................................................................... 12

- Striae weakly to rather strongly impressed, punctures spaced by distances not greater than diameter of a puncture 13

12(11). Frons rather broadly, moderately concave, ornamented by a dense brush of erect, dark yellow hair; declivital interstriae four or more times as wide as striae; interstrial granules minute; color reddish brown; Baja California; Sapium biloculare; $1.5-1.9 \mathrm{~mm}$
10. confinis (Wood)

- $\quad$ Frons feebly impressed, indistinctly concave, ornamented by a small brush of pale yellow hair; declivital interstriae twice as wide as striae; interstrial granules moderately fine; color black; Oaxaca; 1.2-1.8 mm

11. nigrellus Wood

13(11). Interstrial punctures close, spaced by distance equal to diameter of a strial puncture, their anterior margins finely crenulate; striae rather deeply impressed, interstriae slightly convex; frons broadly concave, entire concavity filled by a dense brush of hair; Puebla to Oaxaca; 1.5-1.8 mm ...... 12. recavus Wood

- Interstrial punctures simple 14

14(13). Interstriae distinctly less than twice as wide as striae; female frons convex, male frons concave 15

- Interstriae distinctly more than twice as wide as striae; male and female frons similar16

15(14). Striae moderately impressed, punctures deep, coarse; interstrial punctures fine, deep, close, spaced by distances equal to less than diameter of a puncture; declivital interstriae rather narrowly convex, armed by uniseriate rows of rather coarse tubercles; "Mexico"; Cybistax donnell-smithii; $1.7-2.2 \mathrm{~mm}$ (see also 14. squamifer Wood)
13. splendens (Wood)

- $\quad$ Striae indistinctly impressed, punctures moderately large; interstrial punctures widely spaced, spacing equal to two to four diameters of a strial puncture; declivital interstriae moderately convex, sparsely armed by fine tubercles; S Florida, Puerto Rico, and Panama; Pisidia piscipala; 1.2-1.7 mm

15. vagabundus (Wood)

16(14). Frons broadly concave; frontal pubescence dense, rather long; strial punctures fine, discal interstriae almost twice as wide as striae; declivital striae moderately deep, interstrial tubercles fine; Guerrero; 1.3-1.5 mm .... 16. impressus (Wood)

- Frons shallowly, more narrowly concave, frontal pubescence dense, erect, short; interstriae about as wide as striae, strial punctures coarse; declivital striae narrower, deep, interstrial tubercles rather coarse; Veracruz to Honduras; $1.4-1.5 \mathrm{~mm}$

17. prociduus (Wood)

| 17(9). | Elytral surface minutely reticulate-granulate from apex almost to base; carina transverse, very strongly elevated, narrow, one-fifth as wide as distance between eyes; Costa Rica; Hippomane mancinella; 2.0-2.5 mm ......... 18. opacus Wood |
| :---: | :---: |
| - | Elytral surface smooth, shining; frontal carina less strongly elevated, wider ........... 18 |
| 18(17). | Transverse frontal carina at level of antennal insertion straight, length equal to slightly more than half distance between eyes; epistomal brush broad, dense; declivital interstriae equally, weakly convex; Puebla; $1.4-1.7 \mathrm{~mm}$ |
|  | $\qquad$ 19. fastigius (Wood) <br> Transverse frontal carina on epistomal margin weakly procurved, about onethird as long as distance between eyes; interstriae 9 and usually 1 and 3 slightly elevated $\qquad$ |
| 19(18). | Frontal pubescence in both sexes occupying an area not wider than length of epistomal carina, extending from carina half to two-thirds distance to a point slightly below upper level of eves; declivital interstriae 1 to 3 equally, very feebly convex, granules of equal size; vestiture on elytral declivity short, stout, almost hairlike; Puebla; $1.3-1.5 \mathrm{~mm}$ 20. liratus (Wood) |
| - | Frontal pubescence occupying a much wider area, extending to upper level of eyes; declivital interstriae 1,3 , and 9 weakly elevated, lower half of 2 usually impressed, granules on 2 reduced or absent on lower half |
| 20(19). | Interstrial punctures very small, about half as large as those of striae; interstrial bristles on declivity short, slender, their length equal to half width of one interstriae; Oaxaca; 1.2-1.4 mm <br> 21. gracilens Wood |
| - | Interstrial punctures moderately large, at least two-thirds as large as those of striae; interstrial bristles on declivity longer, stout, their length equal to width of one interstriae; Guatemala; 1.3-1.6 mm ........................................ 22. exilis (Wood) |

## 1. Cnemonyx insignis Wood

Cnemonyx insignis Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):9 (Holotype, male; Moravia, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- This species evidently is allied to panamensis (Blandford), but it is distinguished by the larger size, by the procurved epistomal carina, and by other characters.
Male.- Length $3.5-3.9 \mathrm{~mm}, 2.0$ times as long as wide; color dark brown.

Frons broadly, rather deeply concave on median two-thirds from upper level of eyes to epistoma; surface reticulate-granulate, closely, deeply, rather coarsely punctured in concave area, shallowly, less closely punctured above; slightly less than median half of epistoma armed by an elevated, procurved, transverse carina; vestiture confined to concavity, consisting of rather long, erect, rather abundant, dark hair.

Pronotum 0.9 times as long as wide; widest at base, sides weakly arcuate and converging
toward rather broadly rounded anterior margin; surface smooth and shining on posterior three-fourths, with minute points and fine punctures, anterior fourth rather coarsely subreticulate, dull, faintly, longitudinally etched in lateral areas, punctures very slightly larger in anterior area, much larger laterally. Glabrous.

Elytra 1.1 times as long as wide, 1.2 times as long as pronotum; scutellum as wide as long, not depressed; basal margins of elytra with an irregular raised line; outline as for atratus Blandford; striae rather strongly impressed, punctures fine, shallow, distinct; interstriae smooth, shining, at least twice as wide as striae, moderately convex at base, becoming rather narrowly costiform by declivital base, punctures fine and uniseriate behind, confused toward base. Declivity moderately steep, convex; striae broadly impressed, fine shallow punctures evident; interstriae narrowly, acutely, subserrately elevated; striae and interstriae minutely
reticulate-granulate; costal margin rather coarsely serrate. Rows of very minute interstrial scales evident on declivity.

Female.- Presumably female represented by specimens having frons less strongly impressed, but otherwise similar to male.

Distribution.- Costa Rica to Colombia and Venezuela.
COSTA RICA: Moravia, Cartago, 11-1II-64, 500 m , No. $471,40 \mathrm{~cm}$ cut log, S. L. Wood. OTHER COUNTRIES: Colombia, Venezuela.

Host.- Presumably Virola sp.
Biology.- Dead parent adult specimens were removed from longitudinal galleries in the dry peeling bark of an old $\log$ of an unidentified tree in Costa Rica. In Colombia and Venezuela they occurred in Virola sp. larger than 10 cm in diameter.

Notes.- The above treatment was based on the type series of 7 specimens and on 113 other specimens from Colombia and Venezuela.

## 2. Cnemonyx atratus (Blandford)

Loganius atratus Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6):129 (Lectotype, female; Bugaba, Chiriquí, Panama; British Mus. Nat. Hist., present designation)
Cnemonyx nitens Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. IO(2):9 (Holotype, male; Puerto Viejo, Heredia, Costa Rica; Wood Coll.): Wood, 1972, Bull. Ent. Res. 62:244. Synonymy
Diagnosis.- This species is allied to maculicornis (Blandford), but may be distinguished by characters included in the above key.

Male.- Length 2.0-2.5 mm, 2.1 times as long a wide; color almost black.

Frons moderately to rather shallowly concave on median half from upper level of eyes to epistoma; surface reticulate above, punctures rather coarse, deep, close, becoming finer and closer below in concave area; vestiture short and rather abundant in concave area, longer at sides of this area, evidently glabrous elsewhere. Antennal club subtriangular, finely, closely covered by hairlike pubescence; sutures not evident.

Pronotum 1.0 times as long as wide; widest at base, sides weakly arcuate and converging slightly to slight constriction just behind broadly rounded anterior margin; surface shining, shallowly etched by minute, longitudinally strigose lines, becoming reticulate
anteriorly, punctures fine and elongate posteriorly, almost round and larger anteriorly and laterally. Glabrous.

Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; sides straight and parallel on basal half, then arcuately converging to rather narrowly rounded, suturally subemarginate, posterior margin; striae 1 weakly, others feebly impressed, punctures rather small, deep, close; interstriae smooth, shining, about twice as wide as striae, punctures about half as large as those of striae, uniseriate behind, moderately confused on anterior half of disc; elytral bases with fine raised line; base of interstriae 1 not impressed; scutellum small, as wide as long, almost flush with elytral surface. Declivity moderately steep, convex; striae and interstriae narrower than on disc, striae narrowly impressed; interstriae moderately, broadly convex, shining except sutural half of 1 dull, punctures uniseriate. Vestiture confined to declivity, consisting of sparse minute, short, suberect scales arising from interstrial punctures.

Female.-Similar to male except frons flattened, vestiture reduced; strigose lines on pronotum rather obscure; interstrial punctures on elytral dise not as confused; surface of declivity less brightly shining.

Distribution.- Costa Rica to Panama.
COSTA RICA: Puerto Viejo, Heredia, I2-III-64, 70 m , No. 485, S. L. Wood. PANAMA: Bugaba.

Biology.- Transverse biramous parental galleries were cut in the cambium region of a fallen limb 10 cm in diameter. The eggs had not hatched; consequently, larval mines were not evident.

Notes.- The above treatment was based on two syntypes of atratus and on the type series of 36 specimens of nitens.

Of the three syntypes of atratus mentioned by Blandford, one is missing from its pin. The other two are females. The first female syntype in Blandford's series is here designated as the lectotype of Loganius atratus; it has borne a type label and has been regarded as the type for many years.

## 3. Cnemonyx glabratus (Schedl)

Loganius glabratus Schedl, 1940, An. Esc. Nac. Cienc. Biol. (Mexico) 1:329 (Holotype, female; Tumbalá, Chiapas, Mexico; Schedl Coll.)

Diagnosis.- This species is distinguished from atratus (Blandford) by the female frons, by the slightly smoother, more brightly shining pronotum, and by the sculpture of the elytra as noted below.

Female.- Length $2.4 \mathrm{~mm}, 2.1$ times as long as wide; color very dark brown.

Frons as in atratus except punctures slightly larger, not quite as close; vestiture coarser, slightly longer, concentrated in a pair of submarginal tufts on upper two-thirds except obsolete on upper margin, area between tufts of hair at upper margin rugulose, obscurely, transversely strigose; epistomal process distinctly elevated near but separate from epistomal margin on median third, this transverse carina low, rounded, of about uniform height, smooth.

Pronotum as in atratus except smoother, minute longitudinal striations much more weakly developed.

Elytra about as in atratus except striae rather narrowly, distinctly impressed, punctures rather small, less distinctly impressed; interstriae rather weakly convex, slightly more than twice as wide as striae, smooth, shining, punctures uniseriate, rather close, very fine except about twice as large at base; declivity similar to disc except punctures replaced by fine granules. Very obscure declivital vestiture about as in atratus.

Distribution.- Chiapas.
MENICO: Chiapas: Tumbalá.
Notes.- The above treatment was based on the unique female holotype.

## 4. Cnemonyx errans (Blandford)

Ceratolepis crrans Blandford. 1896, Biol. Centr. Amer., Coleopt. 4(6):127 (Lectotype, male; in "Mexican" tobacco refuse intercepted at Paris; British Mus. Nat. Hist., designated by Wood, 1972, Great Ba$\sin$ Nat. 32:192)
Ceratolepis brasiliensis Schedl, 1936, Archiv. Inst. Biol. Veg. Río de Janeiro 3:104 (Syntypes; Río Grande do Sul, Brazil; Schedl Coll. and Vienna Mus.); Wood, 1972, Great Basin Nat. 32:192. Synonymy
Blandford described this species from several examples intercepted at Paris in tobacco refuse that supposedly came from Mexico. However, except for his series all known specimens are from southern Brazil or
northern Argentina. Because there are no authentic records of this species from North or Central America, it should not be included in any consideration of the fauna of this area.

## 5. Cnemonyx maculicornis (Blandford)

Ceratolepis maculicornis Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6):127 (Lectotype, female: Tolé, Panama: British Mus. Nat. Hist., present designation)
Diagnosis.- In addition to characters summarized in the above key, this species has most of the posterior half of the elytra reti-culate-granulate.

Male.-Length 1.8-2.3 mm, 2.1 times as long as wide; color very dark brown.

Frons moderately, broadly concave from epistoma to vertex; surface reticulate-granulate except on median area of lower third, punctures small, deep, moderately close; median third of lower fourth transversely rugose; median third of epistoma weakly carinate, carina smooth, shining; vestiture very fine, moderately abundant, rather short to moderately long, erect, epistomal brush sparse. Antennal club 1.3 times as long as wide, with abundant, minute hair and sparse scales, sutures not indicated.

Pronotum 0.91 times as long as wide; sides almost straight and parallel on basal fourth, then arcuately converging to moderately rounded anterior margin; surface shining, minutely, longitudinally etched, punctures moderately large, deep, those in lateral areas larger, those in lateral and extreme basal areas tending to be in rows of perhaps three to six punctures each, spaced by distances not greater than diameter of a puncture except more widely spaced near center of disc.

Elytra 1.2 times as long as wide; sides almost straight and parallel on less than basal half, rather narrowly rounded behind; raised line on basal margins indefinite, broken; striae narrowly, rather strongly impressed, punctures small, shallow, distinct; interstriae moderately convex, twice as wide as striae, rather closely, transversely, finely crenulate. Declivity moderately steep, convex; striae slightly deeper than on disc, punctures obscure to obsolete; interstriae as wide as striae, granules minute to obsolete; entire surface finely reticulate-granulate. Vestiture very
short, seen with difficulty, consisting of recumbent interstrial bristles in rows on declivity, confused on disc (usually abraded), each slightly longer than distance equal to diameter of a strial puncture.

Female. - Similar to male except frons flattened below, weakly convex above, pronotal surface not etched posteriorly, with minute impressed points.

Distribution.- Honduras to Colombia.
HONDURAS: La Ceiba, 26-V1H-49, at light. E. C. Becker. COSTA RICA: Osa Peninsula, Puntarenas, I-III67. in a Lauraceae. PANAMA: Tolé, Chiriquí, G. C. Champion: Bugaba, 275-500 m, Champion. COLOMBIA: 27 km NE Montoya, 2-VII-70, I50 m. No. 594, Virola. S. L. Wood.

Host.- Virola sp.
Biology.-Colombian specimens made transverse, biramous parental galleries in a recently cut limb 10 cm in diameter.

Notes.- The above treatment was based on the 16 syntypes in Blandford's series and on 51 other specimens.

Because a type has not been selected from the syntypic series, I here designate the remaining female syntype from Tole in the British Musemm (Natural History) as the lectotype of Ccratolepis maculicomis Blandford. This specimen has been labeled type and considered to be the type for many years.

The series from Colombia tends to have the pronotal punctures slightly larger than specimens from Costa Rica and Panama, but
the difference does not warrant special recognition.

## 6. Cnemonyx panamensis (Blandford)

Fig. Il2
Loganius pimamensis Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6):129 Lectotype, male: Tolé, Chiriquí, Panama; British Mus. Nat. Hist., present designation)
Diagnosis.- This species is distinguished from minusculus (Blandford) by the larger average size, by the confused interstrial punctures and setae, by the different frontal carina of the male, and by other characters mentioned in the above key.

Male.- Length $1.8-2.3 \mathrm{~mm}, 2.2$ times as long as wide; color very dark brown, almost black.

Frons moderately concave from level of antennal insertion to above upper level of eves, a strong, long, transverse carina at level of antennal insertion on more than median three-fourths; epistoma subacutely elevated, with a small, median tubercle; surface above carina rugose-reticulate, punctures obscure; a rather small tuft of long vellow hair on upper two-thirds of each half of concavity, other scattered setae on lower half. Antennal club with suture 1 partly septate, other sutures not indicated.

Pronotum about as in maculicormis except punctures larger, very slightly substrigose.

Fis. 112. Cnemonyx panamensis: 1, female; 2, antenna; 3, protibia.

Vestiture confined to margins and anterior third, of coarse, semirecumbent setae.

Elytra 1.1 times as long as wide, 1.1 times as long as pronotum; sides feebly arcuate from base, arcuately converging on posterior half, rather narrowly rounded behind, striae narrowly impressed, punctures small, shallow, distinct: interstriae three to four times as wide as striae, finely subrugulose, punctures confused, subcrenulate, rather fine to moderately coarse on basal half of disc, smaller behind. Declivity convex, rather gradual; interstriae narrower and more finely sculptured than on disc. Vestiture of short, acuminate. almost scalelike setae of uniformly short length, rather abundant, confused to indistinctly 3 -ranked.

Female.-Similar to male except frons planoconvex. frontal carina absent, epistomal sculpture and tubercle as in male, frontal vestiture of rather short, coarse setae uniformly distributed.

Distribution.- Costa Rica to Panama and Venezuela.

Costi RIC.t: Puerto Viejo. Heredia, I2-III-64. 70 m. No. 476. log, S. L. Wood; Roo Damitas in Dota Mts., San José. 22-VIII-63, 250 m, No. I27, Vismia guiamensis, ל. I. Wool. San Ividro del General. San foré, 13-XII-63. IONO in. No. 310. tree branch. S. L. Word; Finced (iromaco on Ric Coto Brus, Puntarenas. 14-V1I- $63.5(0) \mathrm{m}$, No. 75, tree limb, S. L. Wood. PANAMA: Tole. Chiriquí. G. C. Champion: David. Chiriquí. G. C. Champion. VENEZUELA: Rancho Crande, Aragua, Y-IV-Tい. 1100 m . No. 440 , tree seedling. S. L. Wood.

Host.- Vismia guianensis.
Biology.- The transverse, biramous egg galleries engrave the cambium area from small branches to large boles.

Notes.- The above treatment was based on 11 of Blandford's syntypic series of 16 specimens and on 105 other specimens. Although it has been traditional to regard the first specimen in Blandford's series as the type, I here designate a male from Tolé, the seventh specimen on the sixth pin of those specimens now in the British Museum (Natural History), as the lectotype of Loganius panamensis Blandford. The first syntype is a female bearing a type label; it is considered to be the lectoallotype of this species.

## 7. Cnemonyx minusculus (Blandford)

Loganius minusculus Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6): 130 (Holotype, male; Volcán de Chiriquí, Panama; British Mus. Nat. Hist.)

Loganius tismiae Eqgers, 1929, Wiener Ent. Zent. 46:63 Holotype,male; La Caja, h kin II San Jose. San Jose. Costa Rica; Dentschen Ent. Mus: Wood. 1972. Great Basin Nat. 32:193. Synonymy

Diagnosis.- This species is distinguished from exiguus (Blandford) by mumerous characters that are summarized in the above key.

Male.- Length $1.6-1.7 \mathrm{~mm}, 2.2$ times as long as wide; color almost black.

Frons flattened from epistoma almost to upper level of eyes, very shallowly impressed near center, an elevated. rounded. transverse carina rather poorly developed on median half just above upper level of eves: surface rather finely punctate-gramulate, punctures rather coarse, close: a conspicuous tuft of coarse. dark, rather short setae on median half between carina and upper level of eves. setae evidently always absent along median line. Antenual club subcircular, sutures 1 and 2 rather strongly procurved, 2 reaching middle.

Pronotum as in exigums except surface longitudinally strigose becoming reticulategranulate near anterior margin, punctures rather fime, deep, moderately close. Subglabrous except near margins.

Elytra with outline as in exiguus: striae feebly impressed, punctures fine, shallow, not always clearly defined on disc, obsolete on declivity; interstriae about three times as wide as striae, somewhat rugulose on disc, punctures miseriate, coarse. almost as large as those of striae, very slightly subvulcanate near base. Declivity gradual, convex: interstrial punctures smaller and almost entirely replaced by gramules; strial punctures largely obsolete, surface very minutely rugulose-reticulate to punctured by impressed points. Vestiture of very minute, short, recumbent, strial hair, and suberect, miseriate, interstrial scales: scales on disc very slender, stonter on declivity, about four to six times as long as wide.

Female.- Similar to male except frontal callus slightly smaller and frontal vestiture somewhat shorter.

Distribution- Veracruz to Panama.
MESICO: Veracruz: I 4 km E Huatusco, 7-VII-67, 250 m, No. IT4, rismia, S. L. Wood. GUATEMALA: San Juan, Alta Verapaz, G. C. Champion. COSTA RICA: La Caja, San José, 20-XII-29, Vismia ferruginosa, F. Nevermamn. PANAMA: Volcán de Chiriqui, below 4000 ft $(1300 \mathrm{~m})$, C. C. Champion; Cerro Campana, Coclé, 30-VII-70, 1000 m. H. Howden.

Hosts.- Probably Vismia guianensis.
Notes. - The above treatment was based on the holotype of minusculus, on two cotypes and several topotypes of vismiae, and on six other specimens.

## 8. Cnemonyx exiguus (Blandford)

Loganius exigutus Blandford, I896, Biol. Centr. Amer., Coleopt. 4(6): I30 (Lectotype, male; Bugaba, Chiriquí, Panama; British Mus. Nat. Hist.)
Loganius pumilus Eggers. 1929, Wiener Ent. Zeit. 46:65 (Holotype, male; Turrialba, Costa Rica: U.S. Nat. Mus., 60,392); Wood, 1972, Great Basin Nat. 32:193. Synonymy
Diagnosis.- This species is rather closely allied to panamensis (Blandford), but it is distinguished by characters summarized in the above key.

Male.- Length $1.5-1.9 \mathrm{~mm}, 2.3$ times as long as wide; color black, with whitish elytral setae.

Frons concavely impressed from carina to well above eyes, deepest point immediately above carina, median area above in concavity very feebly elevated; transverse carina thick, broad as concavity, its summit narrow but not acute, located slightly above level of antennal insertion; transversely impressed at level of antennal insertion; surface coarsely reticulate above, finer below; punctures small, indistinct, moderately close; vestiture of sparse, coarse, moderately long subplumose hair. Antennal club 1.3 times as long as wide, sutures 1 and 2 obscurely indicated by long hair; funicular tuft of dark hair rather well developed.
Pronotum 1.05 times as long as wide; outline as in ficus (Schwarz); surface reticulate anteriorly, almost smooth behind, punctures rather small, deep, spaced by one to two diameters of a puncture. Glabrous except for a few stout bristles on anterior fourth.

Elytra 1.2 times as long as wide; sides almost straight and parallel on basal half, rather broadly rounded behind; striae weakly impressed, punctures coarse, deep, rather close; interstriae indistinctly wider than striae, subreticulate, punctures uniseriate, rather coarse, deep, rather close. Declivity convex, rather steep; striae narrower, distinctly impressed; interstrial punctures small. Vestiture confined to posterior two-thirds, consisting of interstrial, uniseriate rows of
erect scales; each scale about equal in length to width of an interstriae, about six times as long as wide.

Female. - Similar to male except frons moderately convex from epistoma to vertex; funicular tuft of hair absent; interstrial punctures on dise subvulcanate, weakly granulate on disc.

Distribution.- Costa Rica and Panama.
COSTA RICA: Turrialba. PANAMA: Bugaba, Chiriquí, G. C. Champion; Madden Forest, Canal Zone, 2-I$64,70 \mathrm{~m}$, No. 367 , S. L. Wood.

Biology.- Transverse, biramous, parental tunnels were constructed in the cambium region of a fallen limb $10-20 \mathrm{~cm}$ in diameter. Camptocerus auricomus shared the same limb.

Notes.- The above treatment was based on Blandford's series of 2 males and one female and on 20 other specimens.

Because a type has not previously been selected from the three syntypes, I here designate a male syntype from Bugaba as the lectotype of Loganius exiguus Blandford.

## 9. Cnemonyx ficus (Schwarz)

Loganius ficus Schwarz. I894. Proc. Ent. Soc. Washington 3:44 (Lectotype, male; Key West, Florida; U.S. Nat. Mus., 4538, present designation)

Ceratolepis nubilus Blackman, 1943, Proc. U.S. Nat. Mus. $94(3174): 380$ (Holotype, male; St. Croix, Virgin Islands; U.S. Nat. Mus., 56558); Wood, 1962, Great Basin Nat. 22:78. Synonymy
Diagnosis.- This distinctive species has the epistomal margin broadly, rather deeply emarginate for this genus; the mandibles are transversely etched on the median half of the visible area; and the costal margin near the elytral apex is smooth, not serrate.

Male.- Length 2.2-2.4 mm, 2.3 times as long as wide; color reddish brown.

Frons broadly, moderately concave from upper level of eyes to epistoma; surface subreticulate, finely, rather closely punctured over entire surface; epistomal margin elevated, smooth, shining; epistomal brush broad, rather conspicuous. Antennal club 1.4 times as long as wide, with three strongly procurved sutures conspicuously marked by rows of pale setae; flagellar tuft of hair well developed.

Pronotum 1.0 times as long as wide; widest one-third length from base, sides rather
strongly arcuate from base, converging slightly on anterior half, rather broadly rounded on anterior margin; surface smooth, shining, with rather numerous minute points posteriorly becoming reticulate toward anterior margin, punctures moderately coarse, rather deep, separated by distances up to twice diameter of a puncture. Glabrous.

Elytra 1.3 times as long as wide; sides almost straight and parallel on slightly less than basal two-thirds, rather narrowly rounded behind; basal margins with a distinctly elevated, irregular line; striae feebly if at all impressed, punctures rather small, deep; interstriae more than twice as wide as striae, smooth, shining, punctures uniseriate, close, only slightly smaller than those of striae. Declivity rather steep, convex; striae narrower, slightly impressed; interstriae feebly convex, surface shagreened, punctures weakly granulate. Vestiture largely confined to declivity, consisting of interstrial rows of short, stout bristles.

Female.- Similar to male except frons very slightly less strongly impressed; funicular tuft of hair shorter.

Distribution.-S Florida to the Virgin Islands.

USA: Florida: Key West, 13-III-I2, Ficus aurea, E. A. Schwarz. VIRGIN ISLANDS: St. Croix, X-XI-63, at light, L. I. Sanders.

Host.- Ficus aurea.
Biology.- Except for the very brief notes of Schwarz, nothing is known of the habits of this species. It was reared from fig branches.

Notes.- This species was named from a long series of syntypes, of which 185 were examined for the above treatment. The male holotype of Ceratolepis nubilus was also examined and compared directly to my specimens.

Because a type has not yet been assigned, I here designate the male specimen in the U.S. National Museum, which for years has been considered to be the type, as the lectotype of Loganius ficus Schwarz.

## 10. Cnemonyx confinis (Wood)

Loganius confinis Wood, 1961, Great Basin Nat. 2I:94 (Holotype, female; 4 miles E La Paz, Baja California; California Acad. Sci.)
Diagnosis.- This species is somewhat similar to nigrellus Wood, but it may be
distinguished by characters presented in the above key.

Male.- Length $1.4-1.9 \mathrm{~mm}, 2.3$ times as long as wide; body color rather dark reddish brown.

Frons broadly, rather deeply concave, from epistomal carina to upper margin of eyes; a smooth, shining, transverse band immediately above epistomal margin elevated and subcarinate, less well developed but similar to that of fastigius, extending almost from lateral margin to lateral margin; reti-culate-granulate above and at sides, finely punctured in lower part of concave area; vestiture confined to concave area, fine, rather long, more abundant below and laterally, fine, sparse epistomal brush apparently rising from beneath lower margin of lower slope of transverse carina. Eye and antenna as in prociduus (Wood).

Pronotum 0.95 times as long as wide, widest on basal third, sides converging somewhat toward constriction just behind rather narrowly rounded anterior margin; basal and lateral margins marked by a fine raised line; surface rather dull, indistinctly, minutely, longitudinally strigose, punctures moderately small, narrowly oval, rather close. Glabrous.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides straight and subparallel on basal two-thirds, rather narrowly rounded behind; humeral angles rounded; striae not impressed except first, punctures very fine, rather close; interstriae at least three times as wide as striae, punctures slightly if at all smaller than those of striae, rather close, in uniseriate rows, surface smooth, dull; elytral bases subcrenulately raised, except impressed near scutellum, several low crenulations on interstriae 2 to 6 ; scutellum small, oval in outline, rather strongly depressed. Declivity evenly convex, rather steep; striae feebly impressed, interstriae $1,2,3,4,7,9$, and 10 very weakly convex with exceedingly minute tubercles in uniseriate rows; interstriae 1 meets costal margin, 2 meets 10,3 meets fused 7 and 9; weakly elevated costal margin with setose punctures, not at all granulate. Vestiture almost obsolete, a few minute interstrial bristles on declivity, none longer than distance equivalent to one-third distance separating rows of bristles.

Female.- Similar to male in all respects. Distribution.- Baja California.
MEXICO: Baja California: 4 miles ( 7 km ) E La Paz, 23-XII-58, Sapium biloculare, H. B. Leech.

Biology.- The type series was reared from tunnels in the bark of branches of the above host.

Notes.- The above treatment was based on the type series of 90 specimens.

## 11. Cnemonyx nigrellus Wood

Loganius niger Wood, 1961 (nec. Eggers, 1933), Great Basin Nat. 21:95 (Holotype, female; 26 km W Tehuantepec, Oaxaca, Mexico; Wood Coll.)
Cnemonyx nigrellus Wood, 1974, Great Basin Nat. 34:278 (Replacement name)
Diagnosis.- This minute species is distinguished from the foregoing species by the black color, by the sexually dimorphic frons, by the simple structure of the elytral declivity, and by the small size. It is more closely allied to gracilens (Wood).

Female.- Length 1.2-1.8 mm, 2.6 times as long as wide; body color black, vestiture white.

Frons broadly flattened, indistinctly concave from epistomal margin to upper level of eyes, transversely impressed on lower third; surface minutely granulose, very finely, closely punctured in impressed area and densely pubescent from epistomal margin to upper level of eyes, setae subplumose, moderately long, pale yellow to almost white, epistomal brush not separated from other setae. Eye rather finely faceted, deeply sinuate on anterior margin. Antennal club about threefourths as long as combined length of scape and funicle; suture 1 reaching only one-third club length from base, all sutures rather broadly procurved.

Pronotum 0.72 times as long as wide, widest on basal third, sides arcuately converging slightly toward narrowly rounded anterior margin; basal and lateral margins marked by a fine, raised line; surface subshining, punctures fine, elongate, rather sparse. Glabrous.

Elytra 1.7 times as long as wide, sides straight and subparallel on slightly more than basal half, rather narrowly rounded behind; humeral angles rather narrowly rounded; striae not impressed, punctures small, distinct, separated by almost twice their own diameters, in regular rows; interstriae one to
three times wider than striae, 1 and 3 wider than 2 and 4, smooth, subshining, punctures sparse, fine, minutely subgranulate on 1 and 3 to base; basal margins almost straight, impressed toward scutellum, finely, irregularly raised from about interstriae 2 to 6 , a few submarginal subcrenulate elevations; scutellum small, depressed, longer than wide. Declivity evenly convex, moderately steep; striae weakly impressed, interstriae feebly convex; interstrial granules moderately large, rounded, rather widely spaced, in uniseriate rows on all interstriae except absent on 4, 6, 8 , and 10 ; costal margin finely raised and sinuate, confluence of interstriae with costal margin or with one another not clear, except possibly 3 and 9 , interstriae 10 minutely serrate on basal half of elytra, 9 minutely serrate on posterior half. Vestiture scanty, consisting of sparse rows of erect, blunt interstrial bristles on declivity and sides.

Male. - Similar to female except frons convex above, impunctate at center, and glabrous.

Distribution.- Oaxaca.
MEXICO: Oaxaca: El Cameron, 22-V1-67, 16 miles ( 26 km ) W Tehuantepec, 8-VII-53, 22-V1-67; all from the same host by S. L. Wood.

Biology. - This species constructed tunnels in the cambium region of its host, which was a low, shrubby, leafless, green plant that produced an abundance of white milky fluid when green stems were cut or broken.

Notes.- The above treatment was based on the type series of 30 specimens and on 80 other specimens.

## 12. Cnemonyx recavus Wood

Cnemonyx recavus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2)$ : 11 (Holotype, male; 48 km E Tehuantepec, Oaxaca, Mexico)
Diagnosis.- This distinctive species is somewhat allied to confinis Wood, but it is readily distinguished by characters summarized in the above key.

Male.- Length $1.5-1.8 \mathrm{~mm}, 2.1$ times as long as wide; color dark reddish brown.

Frons broadly, rather deeply concave from just below upper level of eyes to epistomal margin; concavity densely pubescent, setae moderately, uniformly long; surface of marginal and dorsal areas coarsely reticulate,
with fine, close punctures; surface in concavity obscured by pubescence. Scape short; funicle bearing a dense tuft of long hair; club obovate, with three strongly procurved sutures marked by setae, suture 1 extending almost two-thirds club length from base.

Pronotum 0.92 times as long as wide; basal margin bisinuate, marked by a fine, raised line; widest at base, arcuately converging to a slight constriction just before broadly rounded anterior margin; surface dull, minutely, longitudinally etched, punctures fine, oval, close, moderately deep. Glabrous.

Elytra 1.2 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, rather narrowly rounded behind; basal margins indistinctly raised along a fine line: striae impressed, punctures fine, distinctly impressed; interstriae almost twice as wide as striae, convex, dull. each with a uniseriate row (confused on 2) of fine, short, transverse crenulations, puncture posterior to each crenulation fine, obscure. Declivity convex, moderately steep: about as on declivity, with interstriae 9 weakly elevated and more coarsely tuberculate, 10 with a row of fine tubercles posteriorly. Vestiture confined to declivity, consisting of interstrial rows of very short, flattened bristles each about twice as long as wide.
Female.-Similar to male except frons very slightly less strongly impressed.
Distribution.- Puebla to Oaxaca.
MEXICO: Oaxaca: 48 km E Tehuantepec, 22-V1-67. 120 m, No. 84, S. L. Wood. Puebla: 16 km NW Acatlán, 15-V1-67, 1700 m, No. 36, in "Leche sillo," S. L. Wood.
Biology. - Specimens were attacking recently cut limbs $3-8 \mathrm{~cm}$ in diameter. The biramous parental galleries were transverse.

Notes.- One hundred and sixty-one specimens were examined, including the type series. In the Acatlán series the posterior half of the pronotum tended to be smooth and shining and the punctures behind the interstrial crenulations were more conspicuous. Because these characters overlapped in the two series, geographical races were not designated.

## 13. Cnemonyx splendens (Wood)

Loganius splendens Wood, 1961, Great Basin Nat. 21:88 (Holotype, male; Mexico; U.S. Nat. Mus.)

Diagnosis.- This species superficially resembles ficus Schwarz, but it is much more closely related to vagabundus Wood, from which it may be distinguished by characters summarized in the above key.

Male.- Length 1.7-2.2 mm, 2.3 times as long as wide; color reddish brown.

Frons convex above, transversely impressed above epistoma; epistomal submargin with an impressed line on median two-thirds; surface reticulate above, rather coarsely, closely, deeply sculptured, punctures moderately close above, very close below; vestiture short, inconspicuous. Eye elongate, weakly sinuate on anterior margin; coarsely grantlate. Antenna as in ficus.

Pronotum as long as wide, widest on basal third; sides weakly arcuate and converging toward narrowly rounded anterior margin; surface subshining, punctures rather large, deep, close, oval, somewhat larger in lateral areas. Glabrous.

Elytra 1.5 times as long as wide; sides straight and subparallel on basal two-thirds, rather broadly rounded behind; elytral bases weakly raised along a continuous, irregular line; scutellum small, rounded; striae weakly impressed, punctures moderately large, close deep; interstriae as wide as striae, moderately convex, smooth, subshining, punctures small, distinct, close. Declivity steep, convex; all striae more strongly, narrowly impressed and all interstriae more strongly convex than on disc; all interstriae finely tuberculate, tubercles becoming progressively larger laterally, largest on 9 ; interstriae $1,2,3$, and 5 meet 10,4 joins 5,6 and 8 end short, 7 and 9 fuse apically: 10 very narrow, largely reduced but bearing a few tubercles. Vestiture consisting of rows of short, narrow, scalelike setae, each seta arising from posterior margin of a tubercle.

Female.- Similar to male except frons flattened on a broad area to well above eyes and bearing a subcircular brush of moderately long hair, shorter toward center, extending from epistomal margin to upper level of eyes.

Distribution.- "Mexico."
The type series was intercepted at San Pedro, California, in the bark of Cyhistar donnell-smithii from Mexico.

Notes.- The above treatment was based on the type series of five specimens.

## 14. Cnemonyx squamifer Wood

Cnemonyx squamifer Wood, 1979, Great Basin Nat. 39:138 (Holotype, male; Tikal, Petén, Guatemala: Wood Coll.)
Diagnosis.- This species is distinguished from splendens (Wood) by the smaller size, by the smaller, less strongly impressed strial punctures, by the larger, broader interstrial scales, and by the more strongly impressed male frons.

Male.- Length $1.6-1.7 \mathrm{~mm}, 2.2$ times as long as wide; color yellowish brown.

Frons similar to splendens except more strongly, more broadly concave, vestiture extending slightly above upper level of eyes and closer to margins of eyes.

Pronotum as in splendens except punctures conspicuously smaller.

Elytra resembling splendens except more weakly impressed, punctures much smaller, very close, interstriae twice as wide on striae, less strongly convex, punctures only slightly smaller than those of striae; interstrial setae in rows, slightly longer and much wider than in splendens, each about three to four times as long as wide, about half as long as distance between rows, spaced within a row by length of a seta:

Distribution.- Guatemala.
CUATEMALA: Tikal, Petén, 13-IV-56, 100 m , at light.

Notes. - The above treatment was based on the type series of three males.

## 15. Cnemonyx vagabundus (Wood)

Loganius vagabundus Wood, 1961, Great Basin Nat. 21:89 (Holotype, male; Key West, Florida; U.S. Nat. Mus.)
Diagnosis.- This species is allied to splendens Wood, from which it is distinguished by characters summarized in the above key.

Male.-Length $1.2-1.7 \mathrm{~mm}, 2.5$ times as long as wide; body color light reddish brown.

Frons convex on upper half, flattened on a subtriangular area on lower half, more strongly impressed on a transverse line just above epistoma; narrow epistomal margin smooth and shining; surface reticulate, rather closely, deeply punctured above, punctures setose on flattened area; setae moderately abundant except at center, rather coarse, moderately long. Eye coarsely faceted;
outline sinuate on both anterior and posterior margins. Segments 2 to 7 of antennal funicle as broad as pedicel, each bearing a tuft of long setae on inner margin; club broad, not septate, conspicuously marked by three strongly procurved rows of setae.

Pronotum 0.98 times as long as wide; widest on basal fourth, sides convergently arcuate toward rather narrowly rounded anterior margin, very slightly constricted just behind anterior margin; surface shining, with very feeble indication of minute longitudinal lines, and a few very minute impressed points between moderately coarse, deep, broadly oval punctures. Glabrous.

Elytra 1.5 times as long as wide; sides straight and subparallel on basal two-thirds, narrowly rounded behind; elytral bases not raised along a continuous costa, but with a few finely subcrenulate punctures suggesting a partial raised line; striae feebly if at all impressed, punctures moderately large, very close, deep; interstriae subconvex, smooth, subshining, about one and one-half times as wide as striae, punctures almost as large as those of striae, rather shallow, sparse, spaced at distances about equal to width of interstriae. Declivity moderately steep, convex; striae 1 and 2 more strongly impressed, interstriae $1,2,3$, and 9 more strongly convex than others, their punctures closer than on disc and subserrate on anterior margins; interstriae 5 and 7 also minutely granulate; interstriae 1 and 2 reaching margin, 3,5, and 7 join 9 . Vestiture limited to declivity, consisting of sparse, short, narrowly flattened setae.

Female.-Similar to male except frons more strongly, broadly impressed, impression ending well below upper level of eyes; and declivital sculpture finer.

Distribution.- Florida, Puerto Rico, and Panama.

USA: Florida: Key West, 22, 30-V-12, Ichthyomethia piscipala, No. 9170, E. A. Schwarz. PUERTO RICO: Mona Island, $6,8-\mathrm{lV}-27$, W. A. Hoff. PANAMA: Barro Colorado 1sland, Canal Zone, IX-41, No. 41-20624, 20-V1-41, Z-4816, J. Zetek.

Host.- Pisidia piscipala.
Notes. - The above treatment was based on the type series of 43 specimens. Two additional specimens that probably belong to this species were collected at Little Harbor, British Virgin Islands, 1-IV-58, J. F. G. Clarke.
16. Cnemonyx impressus (Wood)

Loganius impressus Wood, 1961, Great Basin Nat. 21:90 (Holotype, male; Chilpancingo, Guerrero. Mexico; Wood Coll.)
Diagnosis.- This species is allied to prociduus (Wood), but may be distinguished by characters given in the above key.

Description.- Length $1.3-1.5 \mathrm{~mm}, 2.3$ times as long as wide; body color reddish brown.

Frons very shallowly, broadly concave almost to upper level of eyes; a rather wide, subtriangular, smooth, shining epistomal area immediately above epistomal brush; surface of impressed area finely granulate-punctate, largely obscured by abundant, subplumose yellow setae of moderate length. Eye large, coarsely faceted; anterior margin sinuate. Antennal scape short, stout, funicle as long as scape, with segments 2 to 7 each as wide as pedicel and bearing on ventral margin long setae, none of which extend beyond tip of club; club large, broadly obovate, about as long as scape and funicle combined, 1.3 times as long as wide, with three strongly procurved sutures indicated by rows of setae, first not quite reaching middle.

Pronotum 0.96 times as long as wide; widest on basal fourth, sides evenly, arcuately converging toward narrow, but broadly rounded, anterior margin; basal and lateral margins with a fine, raised line; surface apparently minutely, longitudinally strigose on anterior half, becoming smooth posteriorly, and with rather fine, longitudinally elongate punctures, becoming smaller posteriorly and with a few very minute pores interspersed posteriorly. Glabrous.

Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; sides straight and subparallel on slightly more than basal half, rather narrowly rounded behind; humeral angles abrupt; striae 1 distinctly impressed from base, others feebly impressed, punctures fine, distinct, in regular rows; interstriae about two to three times as wide as striae, their surface smooth but very dull, punctures in uniseriate median rows, small, all finely granulate; basal margins almost straight and irregularly raised, interstriae 2 to 6 with up to six poorly developed subcrenulate elevations near base; scutellum small, rounded in outline, scarcely at all depressed. Declivity evenly convex,
moderately steep, all striae rather narrowly, rather deeply impressed; interstriae $1,2,3,5$, 7 , and 9 moderately convex and tuberculate, costal margin and posterior portion of 10 also tuberculate, tubercles on lateral interstriae appearing somewhat larger; interstriae 1 joins costal margin, 2 joins 10,3 joins fused 7 and 9, 4 and 6 end short of 5 . In dorsal profile interstriae 9 appears very finely serrate on posterior half of elytra; 10 finely serrate on anterior half. Vestiture confined to declivity, consisting of rows of short, stout, semierect, almost scalelike setae arising from interstrial tubercles; longest setae about onethird as long as distance between rows.

Female.- Similar to male except frons evidently more strongly impressed.

Distribution.-Guerrero.
MEXICO: Guerrero: Chilpancingo, 22-X-4l, at light, D. M. DeLong.

Notes.- The above treatment was based on the three specimens in the type series. Nothing more is known of the habits or distribution of this species.

## 17. Cnemonyx prociduus (Wood)

Loganius prociduus Wood, 1961, Great Basin Nat. 21:91 (Holotype, female; La Ceiba, Honduras: Wood Coll.)
Diagnosis.- This species is distinguished from impressus (Wood) by the more coarsely sculptured elytra, by the longer, more scalelike, recumbent, declivital setae, and by the very different arrangement of the elytral interstriae.

Female.- Length $1.4-1.5 \mathrm{~mm}, 2.6$ times as long as wide; body color reddish brown.

Frons very shallowly, broadly concave from the sinuate epistomal margin to upper level of eyes; epistomal margin subcarinately raised and obscurely overlapping epistomal brush, with a rather narrow smooth subshining area immediately above epistomal brush; surface of impressed area finely granu-late-punctate, largely obscured by abundant, subplumose, yellow setae of short to moderate length. Eye and antenna essentially as in impressus.

Pronotum 0.95 times as long as wide; widest on basal third, sides converging somewhat toward broadly rounded anterior margin; basal and lateral margins marked by a fine raised line; surface dull, punctures
moderately abundant, rather small except larger in lateral areas, oval, interspaces with a few very minute pores. Glabrous.

Elytra about 1.5 times as long as wide, 1.6 times as long as pronotum; sides straight and subparallel on slightly more than basal half, rather narrowly rounded behind; humeral angles abrupt; striae slightly impressed, punctures moderately large, in regular rows; interstriae less than one and one-half times as wide as striae, punctures almost as large as those of striae, moderately spaced in rows, those toward base with anterior margin elevated, those near declivity appearing subvulcanate, surface almost smooth, dull; basal margins slightly impressed toward scutellum, subcrenulately raised, basal area somewhat irregular but not subcremulate; scutellum almost round in outline, very slightly if at all depressed. Declivity evenly convex, moderately steep, all striae narrower and more strongly impressed than on disc; costal margin and all interstriae except 8 convex and serrate; serrations uniseriate, moderately coarse, evidently larger laterally; interstriae $1,2,3$, and 5 (usually appearing fused to 7 and 9) all reaching costal margin, 4, 6, and 8 end near middle of declivity; 10 with two to five small tubercles near posterior extremity; interstriae 9 serrate on posterior half of elytra, 10 apparently minutely serrate on anterior half. Vestiture confined to posterior half of elytra and sides, consisting of interstrial rows of short, recumbent, spatulate scales arising from interstrial punctures; each scale equal in length to half distance between rows of scales, and each about four times as long as wide.

Distribution.- Veracruz to Honduras.
MEXICO: Veracruz: Lago Catemaco, 16-20-V1-69, D. E. Bright. HONDURAS: La Ceiba, 29-V-49, at light, E. C. Becker.

Notes.- The above treatment was based on the two female specimens that comprise the type series and on nine other specimens.

## 18. Cnemonyx opacus Wood

Cnemonyx opacus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):10 (Holotype, male; Playa del Coco, Guanacaste, Costa Rica; Wood Coll.)
Diagnosis.- This species, at least superficially, resembles insignis Wood, above, but
it is distinguished by the smaller size, by the narrow frontal carina, by the much more extensively granulate elytra, and by characters mentioned in the key. However, the antennal club has an entirely different shape and has three strongly procurved sutures clearly marked by rows of setae, suggesting that the relationship is superficial at best. It is much more closely allied to flavicornis (Chapuis).

Male.- Length $2.0-2.5 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown.

Frons shallowly concave on median half from upper level of eyes almost to epistoma; surface closely, deeply, rather coarsely punctured; median fourth of epistoma bearing a strongly elevated, procurved, transverse carina; vestiture consisting of short, erect, rather abundant, stout hair in concave area. Antennal funicle with inner angle of segments projecting and bearing tufts of long yellow hair; club obovate, longer than wide, with three strongly procurved sutures conspicuously marked by rows of closely set setae.

Pronotum about as long as wide; widest on basal third, sides rather weakly arcuate, converging to weak, transverse constriction just behind rather narrowly rounded anterior margin; surface smooth and shining behind, becoming reticulate anteriorly and toward lateral margins, punctures rather coarse, deep, close, somewhat larger in lateral areas. Glabrous.

Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; sides straight and parallel on more than basal half, rather narrowly rounded behind; scutellum very small, rounded, not depressed; basal margins of elytra marked by a fine, irregular, raised line; striae impressed, punctures rather large, deep, clearly impressed in basal area, obscure behind; interstriae convex, finely, completely reticulate-granulate to granulate (including striae) posteriorly, coarsely punctured on basal third of disc. Declivity moderately steep, convex; striae deeply impressed, punctures obscure; interstriae narrow, strongly convex, minutely granulate, finely subserrate; interstriae 9 moderately elevated, continuing to apex, highest at junction with 3 . Vestiture confined to declivity, consisting of uniseriate rows of minute interstrial scales.

Female.- Similar to male except frons less strongly impressed, almost flat.

Distribution.- Costa Rica.
COSTA RICA: Playa del Coco, Guanacaste, 18-A-63, 1 m . No. 233. Hippomane macinella S. L. Wood.

Blology. - This aggressive species attacked and killed branches up to 8 cm in diameter in vigorous host trees; it also attacked felled trees up to 30 cm in diameter. The biramous parental tunnels were transverse; they engraved both phloem and xylem tissues. Larval mines were moderately short and wandered without any special direction.

Notes.- The above treatment was based on the type series of 68 specimens.

## 19. Cnemonyx fastigius (Wood)

Loganius fastigius Wood, 1961, Creat Basm Nat. 21:93 (Holotype, female: 15 km NW Acatlán, Puebla, Mexico; Wood Coll.
Diagnosis.- This species is distinguished from prociduus (Wood) by the convex frons, by the transverse frontal carina, by the prominent crenulate tubercles of the elytral disc, and by the finer declivital sculpture.

Male.- Length $1.4-1.7 \mathrm{~mm}, 2.6$ times as long as wide; body color rather dark reddish brown.

Frons convex, with a broad, rather sharply elevated, transverse carina just above epistomal margin, its length equal to slightly more than half distance between eyes; lower slope of carina more gradual, smooth, shining, upper slope more abrupt, reticulate, and bearing several setae: surface above carina minutely granulose, impunctate in central area, finely, sparsely punctured at sides and above; vestiture longer and more conspicuous along upper slope of tarina and along epistomal margin, a glabrous area extending from above bases of mandibles across lower slope of carina. Eye and antemna as in prociduus.

Pronotum 0.95 times as long as wide, widest on basal third, sides weakly arcuate behind, abruptly converging anteriorly toward broadly rounded anterior margin; basal and lateral margins marked by a fine raised line; surface dull, minutely, longitudinally strigose, punctures moderately abundant, rather small, oval, interspaces with a few very minute pores. Glabrous.

Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; sides straight and
subparallel on slightly less than basal half, rather narrowly rounded behind: humeral angles abrupt; striae 1 moderately impressed, others feebly if at all impressed; strial punctures small, in regular rows; interstriae at least twice as wide as striae, surface marked by a few irregular lines, punctures slightly smaller than those of striae, each bearing on its raised anterior rim a low, transverse crenulation about equal in length to half width of an interstriae, except crenulations entirely absent on interstriae 4 and 6; basal margins straight, slightly impressed near scutellum, anterior margins subcrenulately elevated and with a few submarginal crenulations on interstriae 2 to 4 ; scutellum round in outline, distinctly depressed below general surface of elytra. Declivity evenly convex, rather steep; striae more strongly, narrowly impressed; interstriae feebly convex, crenulations much narrower, very slightly higher; interstriae 4, 6 , and 8 entirely unarmed; interstriae 1 evidently meets costal margin, 2 meets 10,3 meets fused 7 and 9, 4 and 6 join 5 and end before meeting fused 7 and 9 ; 10 bearing four or five small tubercles posteriorly; posterior costal margin with a few punctures, sinuate. not serrate; interstriae 10 subserrate on basal half of elytra, 9 on posterior half. Vestiture scanty, consisting of stout, sparse, almost scalelike interstrial setae on declivity and posterior portion of disc except on interstriae 4 and 6 , each seta equal in length to about half distance between rows of setae.

Fifth abdominal sternum bearing a low transverse ridge near middle of segment.

Female. - Similar in all respects to male.
Distribution.- Puebla.
MEXICO: Puebla: 9 miles ( 15 km ) NW Acatlán, 13-VII-53, and 17 km NW Acatlán 15-V1-67, 1700 m , No. 36. "Leche Sillo," S. L. Wood.

Biology.- This species was taken in series with recavus Wood from branches of a small tree identified by a local farmer as "Leche Sillo." The parental galleries were biramous and transverse.

Notes.- The above treatment was based on 34 specimens including the type series.

## 20. Cnemonyx liratus (Wood)

[^5]Diagnosis.- This species is very closely related to gracilens Wood and exilis (Wood), but it is distinguished by characters summarized in the above key.

Male.- Length 1.3-1.5 mm, 2.5 times as long as wide; body color dark reddish brown.

Frons convex above, transversely impressed on lower half, with a rather high, narrow, rounded, transverse carina occupying median half, rising abruptly below, sloping gradually above; epistoma with median portion produced in front of mandibles; surface reticulate-granulate, moderately punctured at sides and above; vestiture consisting of a conspicuous brush of short erect yellow hair on median half between carina and a point just below upper level of eyes, epistomal brush emerging from lower margin of smooth, shining, glabrous carina. Eyes and antenna as in prociduus (Wood.)

Pronotum equal in length and width; widest on basal third, sides arcuately converging to moderate transverse constriction just behind broadly rounded anterior margin; almost smooth and subshining posteriorly, punctures moderately coarse and deep, rather close, oval. Glabrous.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides straight and subparallel on basal two-thirds, rather narrowly rounded behind; sutural striae weakly, others not at all impressed; interstriae more than twice as wide as striae, punctures very fine, subgranulate, sparse, surface smooth, subshining; basal margins rounded, raised and subcrenulate, with a few small submarginal crenulations on interstriae 2 to 5 ; scutellum slightly depressed, almost round in outline. Declivity evenly convex; moderately steep; striae weakly impressed, odd-numbered interstriae more nearly convex; interstriae dull, 1 , $2,3,5,7,9$, and costal margin each bearing a row of fine, rather widely spaced tubercles, those on 7, 9, and costal margin larger, 5 devoid of tubercles on lower two-thirds; interstriae 1 joins raised costal margin, 2,3 , and 5 separately join fused 7 and 9,10 virtually obsolete in declivital region. Vestiture sparse, inconspicuous, confined to declivity, except extending onto disc on odd-numbered interstriae; each seta fine, blunt, bristlelike, about half as long as space between rows, separated
by three to four times their length from nearest bristle in same row.

Female.- Similar to male in all respects.
Distribution.- Puebla.
MEXICO: Puebla: 12 miles ( 20 km ) SE Matamoros, 3-VII-53, S. L. Wood.

Biology.- Specimens were collected from the phloem tissues of branches $1-5 \mathrm{~cm}$ in diameter in a tree having reddish peeling bark (Euphorbiaceae).

Notes.- The above treatment was based on 43 specimens including the type series.

## 21. Cnemonyx gracilens Wood

Cnemony.x gracilens Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. IO(2):10 (Holotype, male; 57 km SE El Cameron, Oaxaca, Mexico; Wood Coll.)
Diagnosıs.- This species is very closely related to exilis (Wood), but it may be distinguished by the smaller size, by the more broadly impressed frons with the epistomal carina higher, by the less numerous, more nearly oval pronotal punctures, and by the shorter, finer, less strongly flattened elytral setae.

Male.- Length 1.2-1.4 mm, 2.6 times as long as wide; color dark brown.

Frons as in exilis but more broadly planoconcave, transverse epistomal carina less procurved, slightly higher, occupying at least two-thirds width of epistomal margin; pubescence perhaps a little more abundant.

Pronotum 1.09 times as long as wide; punctures distinctly less numerous than in exilis, each about one and one-half times as long as wide. Glabrous.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; as in exilis except interstrial bristles on declivity much shorter, very weakly or not at all flattened, narrower, not increasing in width apically.

Female.- Similar to male except frons less strongly impressed.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 57 km SE El Cameron, 22-VI-67, No. 81, S. L. Wood.

Notes.- The above treatment was based on the type series of 100 specimens. They were collected from tunnels in the phloem tissues of twigs and small branches up to 3 cm in diameter of a small tree with thin peeling bark, simple leaves, and an abundance of white, milky latex (Euphorbiaceae).

## 22. Cnemonyx exilis (Wood)

Loganius exilis Wood, 1967, Great Basin Nat. 27:119 (Holotype, male; Volcán de Agua, Guatemala: Wood Coll.)

Diagnosis.- This species is rather closely related to liratus (Wood), but it is distinguished by the less strongly serrate costal margins of the elytral declivity, by the more strongly elevated alternate interstriae on the elytral declivity, by the poorly developed funicular tuft of hair, and by the somewhat narrower frons.

Male.- Length $1.3-1.6 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown.

Frons flattened or very feebly concave on lower half, convex above; surface rather coarsely, closely, deeply punctured in impressed area, more sparsely punctured above; median third of epistomal margin bearing a shining, elevated, procurved carina as in liratus; vestiture limited to impressed area, consisting of abundant, erect, stout, uniformly rather short setae.

Pronotum equal in length and width; widest near base, sides weakly arcuate and converging slightly toward rather narrowly rounded anterior margin; surface smooth, shining, punctures rather large, deep, moderately close, oval. Glabrous.

Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; sides straight and parallel on basal two-thirds, narrowly, subserrately rounded behind; striae weakly impressed, punctures moderately large, deep; interstriae shining, slightly wider than striae, very weakly convex, punctures uniseriate, rather small, widely spaced. Declivity rather steep, convex; striae narrower than on disc; interstriae subshining, $1,3,7$, and 9 moderately elevated, 7 joins 9 and continues almost to 3 , elevated interstriae and 2 (somewhat less) uniseriately granulate, granules moderately large, rounded, rather widely spaced; costal margin subserrate toward apex. Vestiture restricted to declivity, sparse; consisting of rows of erect, interstrial scales, each scale about five times as long as wide.

Female.- Similar to male except frons less strongly impressed below, more broadly rounded above.

Distribution.-Guatemala.
GUATEMALA: Volcán de Agua, 19-V-64, 1000 m , No. 592, S. L. Wood.

Biology.- This species attacked branches and small trees $5-10 \mathrm{~cm}$ in diameter. Parental galleries were transverse. The host tree is a Euphorbiaceae very similar to the one described above for gracilens.

Notes.- The above treatment was based on the type series of 83 specimens.

## Cnemonyx longicollis (Blandford)

Loganius longicollis Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6):128 (Holotype, female; "Mexico," tobacco refuse; British Mus. Nat. Hist.)
This species was among several species described by Blandford from material intercepted at Paris in tobacco crates that supposedly came from Mexico. It is definitely established above that one of these, Cnemo$n y x$ errans (Blandford), came from Brazil, not from Mexico as reported. The female holotype of longicollis (Blandford) is very elongate and has several characters not seen in any Central or North American species, but it is very closely related to difformis (Schedl), from Brazil. It should be removed from the Mexican fauna until proof of its existence there is found.

Female (Holotype)- Length $2.4 \mathrm{~mm}, 2.4$ times as long as wide; color dark reddish brown. In the above key it goes to couplet No. 5, but it does not fit either of the alternate statements. Whether or not it has been redescribed from Brazil under another name has not been determined.

## Genus CAMPTOCERUS Latreille

Camptocerus Latreille, 1829, Regne Animale, ed. II, 5:91 (Type-species: Hylesinus aeneipennis Fabricius, monobasic)
Diagnosis.- This genus is very closely related to certain species of Cnemonyx Eichhoff, but it is distinguished by the large, broad ( 1.5 or more times as wide as long) scutellum that is not depressed, not are the elytral bases noticeably depressed or notched for its reception; by the antennal club with suture 1 marked only internally by a septum; by the extensively excavated male frons; by the ambrosial habit; by the larger size; and by other characters noted in the key.

Description.- Length $2.7-8.5 \mathrm{~mm}$, 1.9-2.0 times as long as wide. Color dark brown to black, a metallic sheen on one
species; some species, particularly males, ornamented by variegated patterns formed by erect scales.

Frons broadly, deeply excavated in male from vertex to epistoma and ornamented by hair; convex in female and inconspicuously, finely pubescent. Antennal funicle 7 -segmented; club flattened, somewhat asymmetrical in outline, suture 1 indicated internally by a partial septum, surface very finely, closely pubescent. Pronotum large, broad, unarmed, actually or apparently wider than elytra, lateral margins acutely marked by a fine, raised line. Scutellum flush with elytral surface, moderately large, very broad. Elytral bases acutely marked by a fine, continuous, raised line, not emarginate toward scutellum; declivity gradual, unarmed except in one species. Abdomen ascending rather strongly to
meet elytra at apex. All tibiae with lateral margins unarmed except for large curved spine on outer apical angle.

Distribution.- The Neotropical realm; 17 species have been named from Central and South America; 5 of them occur in Central America.

Biology.-All species are ambrosia beetles. Several species construct a transverse, biramous tunnel in the cambium region. Near the center of this tunnel, but not below the entrance tumnel, a radial tunnel is constructed that penetrates deeply into the wood. This inner tunnel normally branches into two to four tunnels along which eggs are deposited in niches. The larvae expand these into short, broad, larval cradles where pupation occurs. The walls of the tunnels are stained black by a conspicuous fungal growth.

Key to the Species of Camptocerus

1. Discal interstriae 1 and 2 each ending in a large tooth at a point about onethird of elytral length from base, bases of these teeth join to form a fold overhanging base of declivity; Panama; 3.1 mm ................... 1. quadridens Blackman

- Elytra unarmed by conspicuous spines 2
2(1). Elytra glabrous, usually brightly shining, fully mature specimens, usually with a metallic sheen; posterolateral angles of pronotum acute as seen from lateral aspect; male frons broadly, deeply excavated and uniformly pubescent above antennal insertions, lateral margins strongly elevated below antennal insertions; Costa Rica to Brazil and Bolivia; Protium; 4.5-6.4 mm

2. aeneipennis (Fabricius)

- Elytra bearing at least a few lateral or declivital scales; posterolateral angles of pronotum obtuse as seen from lateral aspect 3
3(2). Pronotum closely, very finely punctured, interspaces about three times as wide as punctures; punctures of elytral interstriae sparse, uniseriate; Costa Rica; $2.7-3.2 \mathrm{~mm}$

3. infidelis Wood

- Pronotum densely, finely punctured, interspaces about equal in width to diameter of a puncture; punctures of elytral interstriae rather numerous, confused
4(3). Smaller species; male epistoma unarmed; setae on male declivity of shorter, blunt scales, similar to female; Costa Rica to Brazil; Protium; 2.6-3.5 mm $\qquad$

4. niger (Fabricius)

- Larger species; male epistoma with a conspicuous median tubercle and just dorsad from tubercle a low, slightly procurved, transverse carina; setae on lower half of male declivity long, slender, pointed; Nicaragua to Venezuela; Rheedia, Protitum, etc.; $3.3-4.0 \mathrm{~mm}$

5. auricomus Blandford
6. Camptocerus quadridens Blackman Fig. 113

Camptocerus quadridens Blackman, 1943, Proc. U.S. Nat. Mus. 94(3174):379 (Holotype, male;

Cooper's, near source of Rio Aejeta, Canal Zone, Panama: U.S. Nat. Mus., 56556)
Diagnosis.- The male is distinguished by the large, conspicuous spines on the basal half of the elytra and by other characters

Fig. 113. Scolytini spp.: Camptocerus quadridens, male; 14, Adult; 15, head; 16, antenna; 17, protibia; Cnemonyx bolitiae, male, 18, adult, 19, head; Scolytodes suieteniae, 20, adult, 21, antenna, 22, protibia, 23, female head, 24 , male head: Scolytodes levis; 25, adult. (After Blackman 1943:pl. 16.)
described below. The only species that is even remotely related is costatus Chapuis.

Male.- Length 3.1-3.4 mm, 1.9 times as long as wide; color dark reddish brown.

Frons broadly concave from eye to eye from level of antennal insertion to vertex, a rather strongly, acutely elevated transverse carina on median fourth at level of antennal insertion; concave area reticulate, rather coarsely, uniformly punctured, interspaces about equal to diameter of a puncture. Antenna about as in costatus.

Pronotum 0.88 times as long as wide; sides almost straight and converging anteriorly very slightly on more than basal half, base weakly bisinuate, anterior margin broadly rounded; basal and lateral margins with a fine, raised line; surface smooth, shining, obscurely reticulate in some areas; punctures very fine, distinct. Glabrous except near margins.

Elytra 1.1 times as long as wide, 1.2 times as long as pronotum; disc limited to basal one-fourth of elytra at suture, increasing to slightly more than basal half at lateral margins; discal surface almost smooth, subshining, striae from about 3 to 10 obscurely indicated by fine punctures, some finer interstrial punctures, mostly in rows, also indicated. Declivity beginning on basal fourth, its margin armed on interstriae 1 by a very coarse, pointed spine directed caudad on plane with disc; base of declivity below these spines abruptly, strongly impressed, basal margin more gradually rounded from striae 3 to 7, basal margin continuous with interstriae 7 ; strial punctures moderately coarse, distinct, very shallow; interstriae smooth, shining; interstrial punctures rather widely spaced, most at least slightly tuberculate on anterior margins; subapical margin rather acutely costate near suture. Vestiture consisting of rows of interstrial setae on declivity; setae near base in median area equal in length to up to three times distance between rows, very slender, gradually decreasing in length and increasing in width posteriorly to about one-fourth maximum length, almost scalelike near apex.

Distribution.- Panama.
PANAMA: Cooper's near source of Río Aejeta, Canal Zone, 19-VIII-23. No. 2198, from felled tree, J. Zetek; Cerro Jefe ( $\left.9^{\circ} 12^{\prime} \mathrm{N}, 79^{\circ} 21^{\prime} \mathrm{W}\right)$, Stockwell.

Notes. - The holotype and one other male were examined. Zetek took specimens of aeneipennis (Fabricius) at the same locality and on the same date that he took the holotype of this species. Because the only known host of several species of Camptocerus, including aeneipennis, is Protium, it is possible that the holotype of quadridens came from this host.

## 2. Camptocerus aeneipennis (Fabricius)

Hylesinus aeneipennis Fabricius, 1801, Systema Eleutheratorum 2:392 (Lectotype, male; Essequibo, British Guiana, Copenhagen Mus., present designation)
Hylesinus gibbus Fabricius, 1801. Systema. Eleutheratorum 2:392 (Holotype, female, Essequibo, British Guiana; Copenhagen Mus.); Wood, 1972, Bull. Ent. Res. 62:24. Synonymy
Diagnosis.- This distinctive species may be recognized by the submetallic sheen, by the glabrous pronotum and elytra, by the larger size, and by other characters mentioned in the above key.

Male.- Length $4.5-6.4 \mathrm{~mm}, 1.8$ times as long as wide; color black, elytra with a distinct metallic sheen.

Frons deeply concave from eye to eye from vertex to epistoma, floor of concavity in upper area ascending orad at level of antennal insertion and continuing as a broad trough to epistomal margin; lateral margins subacute from eye to level of antennal insertion then acutely elevated to epistomal margin; surface smooth, minutely punctured; vestiture of abundant, yellow, moderately long hair in upper three-fourths, a few sparse, short, recumbent hairs in troughlike portion. Antennal club 1.4 times as long as wide, devoid of sutures, surface finely pubescent; funicular fringe well developed.

Pronotum 0.8 times as long as wide; widest at base, sides almost straight, converging very slightly on posterior half then abruptly narrowed to distinct lateral constriction just before broadly rounded anterior margin; surface smooth, often wrinkled in posteromedian area, punctures very small, sparse, obscure on disc, larger, more distinct and closer in lateral areas. Glabrous.

Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; sides widest at base, almost straight but converging posteriorly on
basal half, narrowly rounded behind; scutellum twice as wide as long, flat; basal margins with a distinct, elevated line; striae not impressed, punctures fine, close, shallow; interstriae flat, smooth, shining, about six times as wide as striae, punctures minute, close, confused. Declivity gradual, convex; interstrial punctures largely uniseriate. Apparently glabrous; actually, most interstrial punctures bear a very minute hair.

Female.- Similar to male except frons weakly convex, with a very indistinct median carina, surface reticulate, with moderately abundant, short, frontal hair; flagellar fringe absent; pronotal disc smooth, shining.

Distribution.- Costa Rica to Brazil and Bolivia.

COSTA RICA: Peralta, Cartago, IO-III-64, 500 m , No. 465. S. L. Wood; Hamburgfarm on Rio Reventazon. Limon. IO-VI-23, F. Nevermann. PANAMA: Río dejeta, Canal Zone. I9-VIII-28, R. Zetek.

## Host.- Protium spp.

Biology.- Limbs and boles larger than 5 cm in diameter are attacked on cut or injured trees. In Costa Rica the male excavated a transverse, biramous tunnel just below the surface of the wood, about 3 cm in length. From this gallery, but not directly below the entrance hole, a radial tunnel is made extending the gallery directly into the xylem, usually about 3 to 6 cm below the cambium. This inner tunnel normally divides into two to four branches, along which egg niches are constructed at about 3 mm intervals. There are two rows of niches above and one row below the egg gallery. The larvae enlarge the niches into cradles as they grow and later use them as pupation chambers, each completed chamber measuring about 3 by 5 mm . All gallery surfaces are stained black by an ambrosial fungus that evidently served as the principal source of food. In most samples observed in Venezuela the transverse tunnel in the cambium area was omitted and the entrance hole led directly into the xylem.

Notes.- The above treatment was based on seven syntypes of aeneipennis, on the holotype of gibbus, on 45 Central American specimens, and on more than a thousand South American specimens. A male syntype from Essiquibo is here designated as lectotype of aeneipennis.

## 3. Camptocerus infidelis Wood

Camptocerus infidelis Wood, 1969. Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):1I Holotype female: Peralta. Cartago, Costa Rica: Wood Coll.)
Diagnosis.- This small and distinctive species may be recognized by characters summarized in the above key.

Female.- Length 2.7-3.2 mm, 2.0 times as long as wide; color black.

Frons rather strongly convex above, more nearly flattened below, with a distinct, transverse impression just above epistomal margin: surface rather coarsely reticulate and with rather abundant, shallow, indefinite punctures; vestiture sparse, inconspicuous. Antenna essentially as in auricomus Blandford.

Pronotum 0.98 times as long as wide; widest near base, sides rather weakly arcuate, converging slightly to rather strongly rounded anterior angles, broadly rounded in front; surface minutely reticulate and dull on anterior half, almost smooth and subshining behind; punctures minute, sharply impressed, separated by distances equal to two or more diameters of a puncture. Glabrous.

Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; widest at base, sides converging posteriorly to narrow, subemarginate posterior margin; striae not impressed, punctures small, shallow, rather widely spaced; interstriae twice as wide as striae, shining, somewhat irregular, very sparsely punctured, shallow punctures almost as large as those of striae. Declivity gradual, convex; striae weakly impressed. Vestiture consisting of very sparse interstrial scales on sides and declivity.

Distribution.- Costa Rica.
COSTA RICA: Peralta, Cartago. 10-HII-64, 500 m. No. 463. S. L. Wood.

Biology.- Two adult females and several larvae were removed from the same 15 cm longitudinal pith tunnel in a broken tree seedling 1 cm in diameter. The larval cradles were made on the upper and lower surfaces at an oblique angle to the egg gallery.

Notes.- The above treatment was based on the type series of two females.

## 4. Camptocerus niger (Fabricius)

Hylesinus niger Fabricius, 1801, Systema Eleutheratorum 2:393 (Lectotype, male; America meridionali. actually Essequibo, British Guiana: Copenhagen Mus., present designation)

Camptocerus squamiger Chapuis, 1869, Synopsis des Scolytides, p. 51 (Syntypes, a male and a female, Cayenne; Brussels Mus.): Eggers, 1934, Ent. Nachrbl. 8:27. Synonymy
Camptocervs striatulus Hagedorn, 1904, Bull. Mus. Paris 10:547 (Syntypes; French Guyana; Paris Mus.); Eggers, 1933, Ent. Nachrbl. 7:20. Synonymy
Diagnosis.- This species is distinguished from auricomus Blandford by the smaller size and by characters of the male frons described below.

Male.- Length $2.6-3.5 \mathrm{~mm}, 1.8$ times as long as wide; color dark brown, vestiture pale.

Frons as in auricomus except smooth, devoid of tubercle and carina.

Pronotum and elytra as in auricomus except vestiture usually uniformly pale and setae on lower half of declivity only slightly more slender than those on disc.
Female.- Similar to female auricomus except interstrial punctures usually more distinctly, more extensively impressed, with their anterior margins finely granulate.

Distribution.- Costa Rica to Brazil.
COSTA RICA: Hamburgfarm on Río Reventazon, Limón, 24-II-37, in trockenem holz, F. Nevermann. OTHER COUNTRIES: Brazil, Colombia, French Guiana, Peru.

Host.-Protium sp.
Notes.- Three female syntypes from the Copenhagen Collection and one female and one male syntype from the Kiel Collection, now at Copenhagen, were examined. The male is here designated as the lectotype of Hylesinus niger Fabricius. Four Dejean specimens of squamiger Chapius are now in the Chapius collection; of these, two are labeled "Amer. mer." and two are labeled Cayenne. The latter two, a male and a female, are considered to be syntypes. All four specimens are of niger.

Schedl (1940:205) reported this species from Costa Rica, although I have not seen Central American specimens. The above treatment was based on the five syntypes of niger, on the four Chapius specimens of squamiger, and on 20 other South American specimens.

## 5. Camptocerus auricomus Blandford

Camptocerus auricomus Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6):125 (Syntypes; Chontales, Nicaragua, Bugaba, and Volcán de Chiriquí, Panama; British Mus. Nat. Hist.)

Diagnosis.- This species is distinguished by the feebly elevated, procurved, transverse, male, frontal carina at the level of the antennal insertion, with a conspicuous, median, epistomal tubercle in the male, by the distinctive frontal vestiture in the male, and by other characters summarized in the above key.

Male.- Length 3.3-4.0 mm, 1.8 times as long as wide; color dark brown, with abundant, erect scales in a variegated pattern, sparse scales and no pattern in female.

Frons moderately concave from eye to eye, from vertex to level of antennal insertion, ascending orad to a weakly elevated, procurved, transverse carina (precipitous on ventral side only), then flat to epistomal margin; epistomal margin armed by a rather large, rounded, median tubercle; surface of concavity smooth, dull, finely punctured, vestiture of long yellow hair in patches on either side of median line, much longer above, tips of none of hair reaching level of antennal insertion. Antennal club 1.2 times as long as wide; lateral half of suture 1 clearly indicated, septate; funicular fringe well developed.

Pronotum 0.83 times as long as wide; widest near base, sides arcuate, converging very little anteriorly on basal two-thirds, lateral margins slightly constricted just before broadly rounded anterior margin; surface dull, very closely, deeply, finely punctured, interspaces equal to less than diameter of a puncture; vestiture of fine, abundant short hair, and a few longer, coarse bristles on anterior third.

Elytra 1.1 times as long as wide; widest at base, sides almost straight on basal half, conspicuously converging posteriorly, narrowly rounded behind; scutellum twice as wide as long, flat; basal margins indistinctly marked by a raised line; striae not impressed, punctures small, distinct, close; interstriae about six times as wide as striae, flat, shining, punctures rather fine, dense, confused to indistinctly three-ranked, squamiferous. Declivity convex, moderately steep; strial punctures larger, deeper; interstriae less than twice as wide as striae. Vestiture of abundant erect interstrial scales, each about six times as long as wide, except bristlelike and sharply pointed on lower half of declivity.

Female.- Similar to male except frons convex, devoid of carina, tubercle, and ornamental vestiture; funicular tuft absent; pronotum shining, usually glabrous; elytral scales unicolorous, fewer in number, fragile, usually abraded on basal half, not modified on lower half of declivity.

Distribution.- Nicaragua to Venezuela.
NICARAGUA: Chontales, Belt. COSTA RICA: Peralta, Cartago, 10 -III-64, 500 m , No. 465 , probably Protium, S. L. Wood; Río Damitas, Dota Mts., San José, I8-II-64, 200 m , No. 435, Rheedia edulis. S. L. Wood; Finca Gromaco on Río Coto Brus, Puntarenas, 14-VII-63, 500 m, No. 81, S. L. Wood; Guápiles, Limón, 22-VI-66, 100 m, S. L. Wood. PANAMA: Bugaba and Volcán de Chiriqui, Chiriquí, G. C. Champion; Madden Forest, Canal Zone, 70 m , No. $367, \mathrm{~S}$. L. Wood. OTHER COUNTRIES: Venezuela.

Host.- Reedia edulis, and presumably Cedrela sp. and Protium sp.

Biology.- The galleries of this species are basically similar to those of aeneipennis. The transverse tunnel was in the cambium region, although as short as 1 cm at times. More than two branches of the brood tunnel were not observed; and there was only one rank of larval cradles above and one below the egg gallery.

Notes.- The above treatment was based on the Blandford series at the British Museum (Natural History), including the syntypes, and on 71 other Central American specimens.

Genus SCOLYTOPSIS Blandford

Scolytopsis Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6):123 (Type-species: Scolytopsis puncticollis Blandford, monobasic)

Diagnosis.- This genus is very similar to Scolytus Geoffroy, but it may be distinguished by the conspicuously expanded metepisternum that fits into a broadly excised notch on the humeral margin of the elytra, and by the abdomen that ascends abruptly from the posterior margin of sternum 2.

Description.- Length $2.0-3.1 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown.

Frons broadly convex, punctured in female, in male broadly, subconcavely flattened from upper level of eyes to well back on vertex, lower area evidently evenly convex, central area above and below impunctate, smooth, brightly shining, lateral areas bearing a dense brush of long hair, some setae exceed epistomal margin and conceal most of central area above. Antennal club with suture 1 strongly procurved, represented only by remnants of a septum; funicle 7 segmented; scape much shorter than funicle. Pronotum large, unarmed, lateral margins acutely marked by a raised line. Elytral bases narrowly, strongly impressed along suture on basal fifth; scutellum reduced, pointed, elytral bases evidently notched for its reception; declivity very gradual, descending to meet strongly ascending abdomen. Abdomen ascending posterior to hind margin of sternum 2. Tibiae as in Scolytus; tarsi with segment 3 broad, emarginate.

Distribution. - Mexico and Cuba to Argentina; seven species have been named.

Biology.- These species infest the inner bark, where they construct biramous parental galleries and rather long larval tunnels in patterns very similar to those of Scolytus.

## Key to the Species of Scolytopsis

1. Striae weakly, interstriae not at all impressed; elytral surface reticulategranulate on more than posterior half; female frons strongly convex, devoid of a carina, pubescence short, sparse; Veracruz and Cuba to Argentina; 2.0-2.5 mm
2. puncticollis Blandford

- Striae and interstriae narrowly impressed at least on declivity; elytral surface brightly shining except near apical margin; female frons rather strongly, transversely impressed on lower half, a median carina from upper level of eyes to epistoma, vestiture long, fine, moderately abundant; Oaxaca; 2.5-3.1 mm

2. laticollis Wood
3. Scolytopsis puncticollis Blandford Fig. II4

Scolytopsis puncticollis Blandford, 1896, Biol. Centr. Amer., Coleopt. 4(6):123 (Syntypes; Torola, Las Nercedes, Zapote, and Rio María Linda, Guatemala; British Mus. Nat. Hist.)
Diagnosis.- This species may be distinguished by characters summarized in the above key.

Female.- Length 2.0-2.5 mm, 2.2 times as long as wide; color dark brown.

Frons strongly convex, moderately, transversely impressed above epistoma except for a median callus; epistoma weakly elevated, smooth, shining; surface rather coarsely, closely punctured, most punctures longitudinally strigose; vestiture of very short, stout bristles on lower half, a pair of small, longer tufts of hair on epistoma. Antennal club 1.3 times as long as wide, minutely, closely pubescent; sutures not evident except for remnants of a septum on suture 1 .

Pronotum 0.96 times as long as wide; large, widest near base, sides weakly arcuate, not converging on basal two-thirds, rather broadly rounded in front; surface shining, with many minute, impressed points, punctures moderately large on disc, widely spaced, coarse in lateral areas and closer, some reticulation laterally. Glabrous.

Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; slightly narrower than pronotum; sides conspicuously constricted on anterior third, rather broadly rounded behind; elytral bases not distinctly margined; sutural line narrowly, deeply impressed on basal third of elytral length; scutellum greatly reduced, angulate; striae feebly impressed, punctures coarse, deep, moderately coarse; interstriae slightly wider than striae, punctures almost as coarse as those of striae, deep,

Fig. II4. Scolytopsis puncticollis, outline of female. Note the emarginate costal margin of the elvtra.
close; surface dull, reticulate-granulate on about basal three-fourths (variable). Declivity gradual, descending only slightly more than in Scolytus. Vestiture consisting of interstrial rows of moderately long, slender scales.

Male.-Similar to female in all respects except frons as above in generic description.

Distribution.- Veracruz and Cuba to Argentina.

MEXICO: Veracruz: Malinga, I2-III-80, Laguncularia raccmosa, T. H. Atkinson. GUATEMALA: El Zapote, Río Maria Linda, and Torola, Esquintla; Las Mercedes, Quezaltenango; all by G. C. Champion. COSTA RICA: Cañas, Guanacaste, 13-VII-66, 50 m , No. 27, Malpighiaceae vine, S. L. Wood.

Host.- Malpighiaceae, probably Bauisteria cornifolia and Laguncularia racemosa.

Brology.- This species attacked a recently cut woody vine (liana) 8 cm in diameter. The transverse, biramous, parental tunnels included a very large nuptial chamber. Each egg gallery was about $2-3 \mathrm{~cm}$ long; the longitudinal larval mines were usually straight, but some reversed their direction to end near the parent gallery. The mines scored both bark and wood.

Notes.- The above treatment was based on the Blandford series in the British Museum (Natural History), one specimen from Costa Rica, three from Cuba, several from Veracruz, and four from Argentina.

Four specimens, identified as S. argentinensis Eggers, from Argentina, were compared to the type series of puncticollis and to a series from Cuba. This material suggests that the degree of elytral granulation has no taxonomic significance in this genus. Although additional material from other localities should be examined before synonymy is recognized, it is probable that argentinensis Eggers and cubensis Wood are no more than indistinct geographical races of Blandford's species.

## 2. Scolytopsis laticollis Wood

Scolytopsis laticollis Wood, 1968, Great Basin Nat. 28:14 (Holotype, female; 3I km SE Cameron, Oaxaca: Mexico: Wood Coll.)
Diagnosis.- This species is allied to puncticollis Blandford, but it is distinguished by the much smaller lateral punctures on the pronotum, by the narrowly, deeply impressed declivital interstriae, and, in the female, by
the more nearly flattened, much more pubescent frons, with a more prominent median carina.

Female. - Length 2.5-3.1 mm, 2.2 times as long as wide; color dark brown.

Frons broadly convex on upper two-thirds, transversely impressed below, epistomal margin rather abruptly elevated, shining; a narrow, rather strongly elevated median carina extending from upper level of eyes to epistomal elevation; surface coarsely, closely, deeply punctured; vestiture consisting of fine, rather long, moderately abundant, hairlike setae on a subtriangular area from epistoma to upper end of carina.

Pronotum 0.90 times as long as wide; widest just behind middle, sides rather strongly arcuate, converging somewhat on anterior half to the rather broadly rounded anterior margin; surface smooth and shining, with moderately abundant minute points and rather widely spaced, oval punctures of moderately large size, punctures spaced on disc by about one to two times their own diameter except on median line, in lateral areas punctures distinctly less than twice as large as on disc, surface very obscurely reticulate. Glabrous.

Elytra 1.4 times as long as wide, 1.4 times as long as pronotum, slightly narrower than pronotum; sides moderately constricted onefourth pronotum length from base, then arcuate and converging on posterior half to broadly rounded posterior margin; striae narrowly, rather deeply impressed from just behind base to just before apex, punctures rather small, distinct; interstriae at least twice as wide as striae, with punctures as large, deep, and close as those of striae, middle third of each interstriae not impressed on basal fourth of elytra, gradually impressed with increasing depth posteriorly until equal to striae on posterior fourth; general surface shining, with moderately numerous minute points; apical margin elevated, subserrate. Vestiture consisting of stout, short, interstrial setae, becoming almost hairlike on posterior fourth.

Male. - Similar to female except frons modified as in males of related species but with longer setae; setae of elytral declivity more nearly scalelike.

Distribution.- Oaxaca.

MEXICO: Oaxaca: 31 km SE Cameron, 21-VI-67, No. 79, S. L. Wood.
Biology.- This species infested logs and cut limbs of at least three very different host species in a disturbed area in a stone quarry. The biramous, transverse parental galleries and longitudinal larval mines were as in the genus Scolytus; both larval and adult mines scored the wood lightly. One of the host species resembled Plumeria.

Notes.- The above treatment was based on the type series of 15 specimens. All were dead specimens recovered from old, dry bark.

## Genus SCOLYTUS Geoffroy

Scolytus Geoffroy, 1762. Histoire abrégée des insects . . . 1:309 (Type-species: Bostrichus scolytus Fabricius, by designation under the plenary powers) Ekkoptogaster Herbst, 1793, Natursystem aller bekanten in- und auslandischen Insekten, Käfer 5:124 (Type-species: Bostrichus scolytus Fabricuis, designated by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:121)
Coptogaster Illiger, 1807, Mag. Insekenk. 6:321 (Typespecies: Bostrichus scolytus Fabricuis, designated by Hopkins. 1914, Proc. U.S. Nat. Mus. 48:118)
Eccoptogaster Gyllenhal, 1813, Insecta Svecica descripta Coleopt. 1(3):346 (An isotypical emendation of Ekkoptogaster Herbst.)
Scolytochelus Reitter, 1913, Wiener Ent. Zeit. 32(Beiheft):23 (Type-species: Ips multistriatus Marsham. present designation); Schedl, 1948, Zlb. Ges. Ent., Monogr. 1:4. Synonymy
Ruguloscolytus Butovitsch, 1929, Stettiner Ent. Zeit. 90:20 (Type-species: Bostrichus rugulosus Müller, present designation). New synonymy
Diagnosis.- This genus is distinguished from Scolytopsis Blandford by the normal metepisternum, with the costal margin of the elytra entire, and by the abdomen ascending from the posterior margin of sternum 1. It is distinguished from Cnemonyx Eichhoff by the antennal club that has only one or no sutures and by the depressed basal area of the elytra next to the scutellum.

Description.- Length $1.5-5.2 \mathrm{~mm}$, 2.0-2.4 times as long as wide; color dark reddish brown to almost black.

Frous usually sexually dimorphic, male usually less strongly convex or variously impressed, often pubescent, female more strongly convex, rarely with impressed areas, usually less conspicuously pubescent. Eye elongate, sinuate to shallowly emarginate; finely faceted. Antennal scape short; funicle 7 -segmented; club rather large, oval to
obovate, usually minutely pubescent, either devoid of sutures or with suture 1 partly or completely septate and with or without a surface groove. Pronotum large, lateral margins marked by a raised line. Scutellum large, depressed, its apex subacute. Elytra depressed toward scutellum, feebly declivous behind; striate. Anterior coxae rather narrowly separated. Abdomen ascending from posterior margin of sternum 1 to meet apex of elytra, sternum 2 usually ascending abruptly, often impressed, armed, or both: sexually dimorphic in most species.

Distribution.- Most of the northern hemisphere and South America; more than 100 nominate species are known; 28 species occur in North and Central America.

Biology.- The species are phloeophagous in both coniferous and broadleafed trees. All temperate species are monogamous: some of the tropical species are bigamous. The entrance tunnel of the (usually) biramous gallery system is formed by the female. The
parental gallery system engraves the wood moderately to deeply; it may be parallel, diagonal, or transverse to the grain of the wood. The larval mines wander aimlessly away from the parental tunnels in many species; in others they form a very definite pattern, usually engraving the wood rather deeply near their ends. Most species pupate in the cambium area; a few pupate $1-2 \mathrm{~cm}$ below the surface of the wood. Those species inhabiting the cooler regions produce one generation each year; evidently those in warmer climates may produce two or more generations annually.

Notes.- The larger European elm bark beetle, scolytus (Fabricius) has been intercepted in the United States on numerous occasions and has been successfully reared in native elm bolts; however, no successful introductions of this species are known. It is included below to avoid possible confusion with other species in the event that it does become established.

## Key to the Species of Scolytus

1. Suture between abdominal sterna 1 and 2 clearly visible, at least in lateral areas; suture 1 on antennal club strongly angulate, marked by a clearly visible external groove; temperate species, including all species north of Mexico and those from coniferous hosts in Mexico2

- Suture between abdominal sterna 1 and 2 entirely obsolete; antennal club without external evidence of a suture, a shining line indicated in one species; tropical species, never in coniferous hosts23

2(1). Abdominal sternum 2 oblique to subvertical, never armed; sternum 5 with subapical, transverse ridge absent in male, rather weakly developed in female; elytral disc conspicuonsly pubescent in two species; in broadleafed hosts3

- Abdominal sternum 2 vertical to concave, this or other sterna frequently armed by conspicuous spines; sternum 5 with a strongly elevated, transverse, subapical ridge (except male quadrispinosus); elytral disc always glabrous 6
3(2). Profile of abdominal sternum 2 convex; disc of pronotum with punctures coarse, close; strial and interstrial punctures in rows, equally coarse; elytral setae in rows extending to base, each seta about equal in length to distance between rows; S Canada to N Mexico; Malus, Pyrus, Prumus; 1.5-2.7 mm

1. rugulosus (Müller)

- Profile of abdominal sternum 2 flat to concave; pronotal punctures on dise smaller; larger species4

4(3). Strial and interstrial punctures moderately coarse, equal in size; elytral dise with rows of fine, very long, interstrial hair; frons rather coarsely aciculate and moderately pubescent in both sexes; North Dakota and Pennsylvania to Texas and Florida; Celtis; 2.8-4.2 mm
2. muticus Say

- Strial punctures larger than those of interstriae; elytral disc glabrous
5(4). Frons finely aciculate and glabrous in both sexes; Ohio and Ontario to
Maryland; Malus, Pyrus, Ulmus; $3.1-4.1 \mathrm{~mm} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ~ 3 . ~ m a l i ~(B e c h s t e i n) ~$
- Frons rather coarsely, closely punctured, not at all aciculate, pubescent from epistoma to near vertex, vestiture shorter and rather sparse in female, rather abundant and longer in male; Illinois to Texas; Fagus, Celtis; 3.5-4.5 mm

4. fagi Walsh

6(2). Antennal club broad 1.3 times as long as wide; transverse subapical ridge on sternum 5 poorly developed; male sternum 2 deeply concave, 3 armed by three coarse spines, 4 armed by one median spine, segment 5 shorter than 3 or 4 , female sterna unmodified, unarmed, opaque; striae slightly impressed, punctures rather coarse, interstrial punctures very fine; Iowa and Quebec to Texas and Georgia; Carya; 2.9-5.0 mm
5. quadrispinosus Say

- Antennal club more slender, at least 1.5 times as long as wide; transverse ridge on sternum 5 more strongly developed; sternum 3 never armed 7

7(6). Transition from sternum 2 to 3 oblique or rounded, 2 always with a well
developed median spine in both sexes ..... 8

- Transition from sternum 2 to 3 abruptly angulate, margin often strongly produced in males, those species with male angle poorly developed lack median spine, females either with spine absent or represented by a small granule if margin not produced as in male
8(7). Sternum 2 with base of spine touching its anterior margin; striae and interstriae equally, narrowly impressed, their punctures subequal in size; British Columbia and Nova Scotia to California and Florida: Ulmus; 1.9-3.1

6. multistriatus (Marsham)

Base of spine remote from anterior margin of sternum 2; interstriae never
impressed, punctures smaller than those of striae; in coniferous hosts ...................... 9
$9(8)$. Spine on sternum 2 at middle of segment, its base remote from posterior margin of segment; abdominal sterna more coarsely punctured; male frons flattened from eye to eye, rather coarsely aciculate-punctate (about equal to laricis); Alaska and Nova Scotia to California and New York; Picea; 2.2-2.8 .........
7. piceae (Swaine)

- Base of spine on sternum 2 in contact with posterior margin of segment; abdominal sterna more finely punctured
10(9). Frons shallowly, finely aciculate, punctures fine, male feebly convex between eyes; female spine on sternum 2 conical, male spine more slender; British Columbia and Alberta to California and New Mexico; Pseudotsuga; $2.0-2.4 \mathrm{~mm} . .$. 8. unispinosus LeConte
- Frons deeply, rather coarsely aciculate-punctate, male frons flat between eyes; female spine on sternum 2 laterally compressed, male spine stouter; British Columbia and Montana to Oregon:2 .4-3.0

9. laricis Blackman

11(7). Male and female sternum 2 without any indication of a median spine, tubercle,
or carina (some male praeceps with a feeble tubercule or carina) ............................ 12
Male sternum 2 with a median spine, tubercle, or carina (rather weakly
developed in some species), female usually with a similar but smaller structure ..... 17
12(11). Frons granular, pubescence rather dense, fine, moderately short; abdominal sterna 3 and 4 shining, each armed by a median tubercle on posterior margin; introduced from Europe but not established; Ulmus; 3.5-5.2 mm

[^6]13(12). Angle formed at junction of sterna 1 and 2 usually obtuse, margin never projecting caudad, sternum 2 at least weakly convex; posterior apical margin of elytra sometimes with a small, abrupt emargination in line with interstriae 3; crest of transverse carinate ridge on male sternum 5 sometimes as close or closer to anterior margin than to posterior margin of segment $14 a$
Posterior margin of sternum 1 acutely projecting, 2 concave; apical margin of
elytra entire, either smooth or minutely serrate; male sternum 5 with
transverse ridge much closer to apical margin than basal margin of segment ....... 14 c
14a(13). Transverse carina on male sternum 5 much more strongly elevated, particularly on median third, its crest at median line closer to anterior margin than to posterior margin of segment; posterior margin of elytra distinctly notched at a point in line with interstriae 3 ; largest setae on median half of abdominal sternum 1 as coarse and as long as those on metasternum; Wyoming to Durango and Nuevo León; Pseudotsuga; 2.2-3.5 mm (see also 11. virgatus Bright) $\qquad$ 12. reflexus Blackman

- Transverse carina on male sternum 5 more uniformly, less strongly elevated, its crest at median line closer to posterior margin than to anterior margin; elytral margin not emarginate at position of interstriae 3 ; setae on median half of sternum 1 much shorter and finer than longest setae on metasternum
$14 \mathrm{~b}(14 \mathrm{a})$. Striae narrowly, distinctly impressed from base to declivity, punctures larger, closer, spaced by one to two diameters of a puncture; color uniformly very dark brown; odd-numbered discal interstriae almost never with setae; declivity more gradual, shorter; British Columbia to N California and E Montana; Tsuga; 2.2-3.5 mm ............................................................................. 14. tsugae Swaine
- Striae not impressed, occasionally part or all of 1 or 2 weakly impressed, punctures smaller, spaced by two to three diameters of a puncture; elytra usually of conspicuously lighter color; odd-numbered interstriae usually with a few setae; declivity more abrupt, slightly longer; British Columbia and N California to Wyoming and N Utah; Pseudotsuga; 2.2-3.0 mm

13. monticolae Swaine
$14 \mathrm{c}(13)$. Surface of abdominal sterna brightly shining; projecting margin of male ster-
num l more than twice as high as thick at median line; male frons above upper
level of eyes flat to weakly convex ......................................................................... 15

- Surface of abdominal sterna dull, reticulate; height of projecting margin of male sternum 1 about equal to its thickness; male frons above eyes moderately to rather strongly convex
$15(14 \mathrm{c})$. Punctures on elytra and on abdominal sterna much smaller; male frons less deeply, less closely aciculate; Nuevo León to Puebla; Abies religiosa; 3.0-3.7 mm 15. hermosus Wood
- Punctures of elytra and abdominal sterna rather coarse; male frons more deeply, more closely aciculate; Utah and Colorado to Arizona and New Mexico; Abies concolos; 2.5-3.1 mm

16. robustus Blackman
$16(14 \mathrm{c})$. Larger species; median length of sternum 2 equal to 1.2 times combined lengths of 3 and 4 ; male sternum 2 with surface of concave area small, irregular, its anterior margin very thick; male frons below upper level of eyes weakly convex to transversely impressed; Oregon to California; Pseudotsuga; 2.7-3.3 mm 17. oregoni Blackman

- Smaller species; median length of sternum 2 equal to 1.7 times combined lengths of 3 and 4 ; male sternum 2 with floor of concave area flat, extensive, its anterior margin rather thin, particularly in lateral areas; male frons below upper level of eyes more strongly convex; British Columbia and Idaho to California; Abies; $2.0-2.7 \mathrm{~mm}$

18. praeceps LeConte

17(11). Very large species; apical margin of elytra shallowly to rather deeply emarginate at interstriae 3; posterior margin of male abdominal sternum 1 weakly produced, less than half as high as thick (male aztecus not seen), summit of spine at posterior margin of segment 2 ; abdominal surfaces brightly shining

- Smaller species; apical margin of elytra entire, usually minutely serrate; abdominal surfaces dull, usually reticulate
18(17). Apical margin of elytra with a weak to moderate emargination in line with interstriae 3; strial and interstrial punctures subequal in size; margin of epistomal process almost straight; elytra almost black; Puebla-Tlaxcala to Mexico; Abies religiosa; 3.6-4.5 mm

19. mundus Wood

- Apical margin of elytra rather deeply emarginate at interstriea 3 and 6; strial punctures about twice as large as those of interstriae; margin of epistomal process strongly recurved: elytra reddish brown; Michoacán; Abies religiosa; $4.5-5.3 \mathrm{~mm}$

20. aztecus Wood

19(17). Summit of spine on male sternum 2 at or anterior to middle of segment, carina descending to posterior margin of segment; female sternum 2 with a weak median carina on posterior half present or absent but never with a tuberculate summit at posterior margin of segment (some females apparently indistinguishable from some females of praeceps and obelus); Oregon and Montana to California and Colorado; Abies, Picea, Tsuga; 2.0-2.6 mm
21. opacus Blackman

- Summit of spine on male sternum 2 at posterior margin of segment 20

20(19). Posterior margin of male sternum 1 weakly produced, about half as high as thick, small pointed tubercle on 2 at posterior margin; British Columbia and Montana to California and New Mexico; Abies, rare in other hosts; 2.5-3.8 mm
22. ventralis LeConte

- Posterior margin of male sternum 1 strongly produced, about twice as high as thick

21(20). Smaller species; male frons largely convex, weakly flattened on median third below upper level of eyes, vestiture sparse; epistomal process weakly developed, its lateral angles not elevated; male spine on posterior margin of sternum 2 conspicuous, sharply pointed; Nevada and Colorado to New Mexico; Abies concolor; $2.0-2.4 \mathrm{~mm}$
23. obelus Wood

- Larger species; male frons broadly flattened on at least lower half, flat to rather weakly convex to vertex, vestiture moderately abundant, rather long 22

22(21). Male sternum 4 unarmed; female interstrial punctures with their anterior margins elevated to form a tubercle; British Columbia to California; Abies; 2.9-4.4 mm
24. subscaber LeConte

- Male sternum 4 with a median spine on posterior margin, 2 and 3 with a feeble tubercle in comparable position; female interstrial punctures normal, unarmed; California; Abies bracteata; $3.2-3.8 \mathrm{~mm}$

25. dentatus Bright

23(1). Male frons flat or convex, without a conspicuous median elevation; abdominal sternum 2 armed or not, if armed then longitudinal basal width of process greater than its height, except male nodatus, which also bears a spine on sternum 4; monogamous species

- Male frons with a conspicuous median elevation slightly below center; abdominal sternum 2 with a conspicuous subconical spine arising from its anterior half, sternum 4 never armed; bigamous species

24(23). Male sternum 1 with posterior margin abruptly, subacutely carinate on median half, 2 unarmed; female transition from sternum 1 to 2 rounded, anterior fourth of 2 with a rounded, ovate elevation about half as high as wide, about twice as long as wide; Costa Rica to Brazil; 3.2-3.9 mm
26. costellatus Chapuis

- Male sternum 2 armed by a process higher than wide 25
$25(24)$. Sternum 2 armed by a strongly, laterally compressed process, its basal length arising from anterior two-thirds of segment in both sexes, sternum 4 never armed; frons finely aciculate, subglabrous in male, pubescence moderately abundant in female; Jalisco to Venezuela; $2.0-2.6 \mathrm{~mm}$

27. cristatus Wood

- Male sternum 2 armed by a blunt spine arising from less than anterior half of segment, sternum 4 armed by a large, rounded, median nodule, female sterna marmed; transition from sternum 1 to 2 abruptly angulate in both sexes; Costa Rica to Panama; 2.7-3.7 mm

28. nodatus Wood

26(23). Abdominal sternum 2 coarsely, rather deeply punctured, width of interspaces average about half diameter of a puncture; male sternum 2 oblique, spine conical; male frons convex, median elevation feebly developed, its width about one-sixth as wide as space between eyes, vestiture in lateral areas short, more generally distributed; female frons weakly convex, with a sparse row of long hair on lateral and dorsal margins; Costa Rica; 2.0-2.4 mm (see also 33. marginatus Chapuis)
34. torulus Wood

- Abdominal sternum 2 finely punctured, width of interspaces two or more times greater than diameter of a puncture; abdominal sternum 2 vertical; median frontal elevation of male conspicuous, wider: female frons with vestiture much more abundant
27(26). Male frontal elevation dorsoventrally compressed, area between elevation and epistoma concavely impressed, area above eyes convex; female frons weakly convex, reticulate, aciculate, upper and lateral margins ornamented by a dense brush of very long hair; Vera Cruz and Cuba to Venezuela; 2.1-3.2 mm (see also 31. incognitus Eggers)
- Male frons not concave between epistoma and frontal elevation; female frons shallowly concave, vestiture abundant, uniformly distributed, sparse above upper level of eyes (see also 32. nevermami Schedl)
28(27). Male frons flattened from epistoma to vertex, its surface obscurely, finely reticulate, median elevation obtusely conical: male abdominal vestiture abundant, short, stout except for tuft of long hair immediately posterior to spine on sternum 2; Nayarit and Vera Cruz to Costa Rica; 2.4-3.6 mm

29. propinquus Blandford

- Male frons moderately convex, strongly reticulate. low median elevation dorsoventrally compressed; abdominal sternum 2 with vestiture long, without a tuft of hair posterior to spine; Navarit; 2.4-2.6 mm 35. laetus Wood

## 1. Scolytus rugulosus (Müller)

Scolytus rugulosus intermedius Sokanovskii, 1960, Ent. Obozr. 39:674 (Bukhara, Central Asia; not seen)
Diagnosis.- This introduced species resembles certain Cnemonyx species much more closely than it does native American Scolytus species. It is distinguished from other species of Scolytus by the more nearly declivous elytra that are pubescent to their bases and by the gradually ascending abdominal sternum 2.

Male.- Length $1.5-2.7 \mathrm{~mm}, 2.2$ times as long as wide; color very dark brown.

Frons broadly convex, weakly impressed on lower fourth toward median line; surface subshining, rather finely aciculate; punctures fine, rather obscure; vestiture fine, moderately abundant, rather long.

Pronotum 1.0 times as long as wide; widest one-third pronotum length from base, sides strongly arcuate, converging anteriorly to rather broadly rounded anterior margin; surface shining, punctures coarse, close, deep,
much larger in anterolateral areas, most interspaces narrower than punctures, with a few impressed points.

Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal half, then arcuately converging to broad, shallow, sutural emargination; surface shining; striae and interstriae closely, coarsely, equally, uniseriately punctured, striae weakly impressed, interstrial punctures setose. Declivity moderately steep for this genus; posterior margin finely subserrate. Vestiture of interstrial rows of erect, stout hair to base of elytra, of moderate length.

Female.-Similar to male except frons more strongly convex and frontal vestiture slightly less abundant.

Distribution.- Cosmopolitan, wherever the hosts are cultivated.
CANADA: All southem provinces where apples grow: USA: All states. MEXICO: Chihuahua.

Hosts.- Malus spp., Prunus spp., Pyrus sp., and less common in Crataegus spp., Cydonia sp., Ulmus spp., etc.

Biology.- Cut, broken, or unthrifty limbs and branches are usually selected for attack. The female forms the entrance tunnel and the uniramous egg gallery without a nuptial chamber. The male joins her early in the process of gallery formation and removes frass

Fig. 115. Scolytus rugulosus: a, b, adult; c, pupa; d, larva. (After Chittenden 1909:1.)
that she excavates. Larval mines are irregular; pupation occurs about $1-2 \mathrm{~cm}$ below the surface of the wood in the overwintering brood chamber, but may take place in the cambium region during the summer months. The larvae pupate during the late winter or early spring and emerge from about midApril to mid-May. Up to four generations may be produced each year in warmer climates; this may be reduced to less than two in the northern areas.

Notes.- Several hundred specimens were examined. No attempt was made to locate or evaluate the types of this introduced species. In Europe and Asia distinct geographical races have been reported as indicated in the above synonymy.

## 2. Scolytus muticus Say

Fig. 117
Scolytus muticus Say, 1824, J. Acad. Nat. Sci. Philadelphia 3(1):323 (Syntypes; Missouri; lost)
Diagnosis.- In this species, mali (Bechstein,) and fagi Walsh the male sternum 5 is inflated and its posterior margin is poorly developed in both sexes. This species is distinguished from the other two by the very long, fine hair. on the elytra, by the sculpture of the frons, and by the male sternum 5 .

Male.- Length 2.8-4.2 mm, 2.1 times as long as wide; color very dark reddish brown.

Frons impressed from eye to eye from epistoma to vertex, flat to obscurely concave on upper half, lower half irregularly, weakly concave, epistoma shallowly, broadly emarginate; surface shining, strigose, punctures fine, mostly obscure. Vestiture of very long, fine hair, rather sparse in central area, abundant on margins.

Pronotum 0.92 times as long as wide; widest just behind middle, sides moderately arcuate from base, a narrow, abrupt constriction immediately behind anterior margin; surface brightly shining, impressed points obscure, punctures rather small, moderately close, deep, distinctly larger in anterolateral areas. Vestiture confined to lateral areas, of fine hair.

Elytra 1.13 times as long as wide, 1.1 times as long as pronotum; sides straight and parallel on basal half, arcuately converging very slightly on posterior half, then abruptly rounded to broad, feeble emargination on median third at sutural apex; surface brightly
shining; striae and interstriae rather narrowly, weakly impressed, striae slightly deeper, punctures of equal size, rather small, moderately deep, decreasing in size toward declivity. Declivity gradual, short; subapical margin a smooth costa, apical margin subserrate. Vestiture of very long, fine hair in interstrial rows to base; each hair two to four times as long as distance between rows.

Sternum 2 ascending abruptly on its basal two-thirds. Sternum 5 with a pair of rather strongly elevated areas on basal two-thirds, subconcavely, rather strongly impressed on posterior third; inflated area with abundant, fine, long hair.

Female.- Similar to male except frons less extensively, less strongly impressed, more nearly convex, vestiture greatly reduced; sternum 5 without elevated or impressed areas, weakly concave on median half, subapical costa moderately developed, vestiture sparse, rather short; sterna shining.

Distribution.- North Dakota and Pennsylvania to Texas and Florida.

USA: District of Columbia, Florida, Kansas, Kentucky, Maryland, Mississippi, Missouri, New Jersey, North Dakota, Ohio, Oklahoma, Pennsylvania, South Carolina, Texas, West Virginia.
Host.- Celtis occidentalis.
Biology.- This species attacks limbs and boles of cut and unthrifty material. The biramous parental tumnels are transverse.

Notes.- The type is lost, but the species is easily identified from the original description. My material was comapred to that of LeConte, Blackman, etc., and is of the same species as reported by them.

## 3. Scolytus mali (Bechstein)

Bostrichus mali Bechstein, 1805, Vollstandige Naturgeschichte der Schädlichen Forstinsekten 3:882 (Syntypes, presumably Germany; not located)
Eccoptogaster pruni Ratzeburg, 1837, Die Forstinsekten, p. 186 (Syntypes; presumably Germany; not lo(ated); Reitter, 1913, Wiener Ent. Zeit. 32(Beiheft ): 19. Synomymy
Eccoptogaster pyri Ratzehurg, 1837, Die Forstinsekten. p. 186 (Syntypes; presumably Germany; not to(ated); Ratzeburg, 1839, Die Forstinsekten, p. 229. Synonymy

Eccoptogaster castaneus Ratzeburg, 1837, die Forstinsekten, p. 187 (Syntypes; presumably Germany; not located); Eichhoff, 1880, Die Europäischen Borkenkäfer, p. 154. Synonymy
Scolytus sulcatus LeConte, 1868, Trans. Amer. Ent. Soc. 2:167 (Holotype, female; New York; Mus. Comp.

Zool.); Brown, 1950, Canadian Ent. 82:203. Synonymy
Scolytus nitidulus Chapuis, 1869, Synopsis des Scolytides, p. 59 (Holotype, female: France meridionale; presumably Brussles Mus.); Hagedorn, 1910, Coleopt. Cat. 4:85. Synonymy
Scolytus mali abberation strigilatus Reitter, 1913, Wiener Ent. Zeit. 32(Beihett):19 (No status in nomenclature)
Scolytus bicallosus Eggers, 1933. Ent. Nachrbl. 7:75 (Holotype, male; Sagver, Ungarn; U.S. Nat. Mus. 60494): Eggers, 1942, Arb. Morph. Taxon. Ent. Berlin-Dahlem 9:280. Synonymy
Diagnosis.- This introduced European species is distinguished from native American species by the oblique abdominal sternum 2, however sternum 5 is very similar to that of fagi Walsh, suggesting at least a distant relationship. From fagi this species is distinguished by the aciculate frons, by the more finely punctured pronotum, and by the finer strial punctures.
Male.- Length 3.1-4.1 mm, 2.2 times as long as wide; color very dark brown.

Frons shallowly, subconcavely impressed on median two-thirds from epistoma to upper level of eyes; surface shining, aciculate on impressed area, punctures fine, deep, rather numerous, evident on upper half and in lateral areas; vestiture of fine hair, short and sparse on upper half, longer and more abundant below.

Pronotum 1.0 times as long as wide; about as in muticus except slightly narrower than in front; punctures fine to minute. Glabrous.

Elytra 1.2 times as long as wide; about as in muticus; striae feebly impressed, punctures fine; interstriae about four times as wide as striae, smooth, shining, punctures about half as large as those of striae, confused toward base, uniseriate on more than posterior half. Almost glabrous.

Sternum 2 subvertical to oblique. Sternum 5 subinflated on its apical half before apex as in fagi, not transversely carinate; vestiture of minute hair.

Female.-Similar to male except frons rather strongly convvex, punctures smaller, less clearly impressed; abdominal sternum 5 almost flat, with subapical carina moderately elevated, acute.

Distribution.- Ontario and New York to Ohio and Maryland; most of Europe, N Asia, and N Africa.

CANADA: S Ontario. USA: Connecticut, Maryland, New Jersey, New York, Ohio, Pennsylvania.

Hosts.- Malus spp., Prunus spp., Pyrus sp., Ulmus spp.

Biology.- This species attacks unthrifty or cut limbs and boles. The gallery system apparently is as in rugulosus except that a large nuptial chamber is formed at the end of the entrance tunnel, from which one longitudinal egg gallery extends. Pupation occurs in the wood as in rugulosus. The winter may be passed as partly grown larvae in the cambium or as mature larvae in pupation cells (Pechuman 1938). There is one generation each year in New York.

Notes.- The above treatment was based on 38 European specimens, on the holotype of sulcatus, and on 16 other specimens.

## 4. Scolytus fagi Walsh

Scolytus fagi Walsh, 1967, Practical Ent. 2:58 (Six syntypes: Southern Illinois; not located)
Diagnosis. - This species is distinguished from mali (Bechstein) by the closely punctured frons, with no indication of aciculation, by the larger pronotal and strial punctures,

Fig. 116. Scolytus rugulosus, galleries. (After Ratzeburg 18.37:Taf. X1.)
and by the uniseriate interstrial punctures on the basal half of the elytra.

Male.- Length $3.5-4.5 \mathrm{~mm}$, 2.1 times as long as wide; color dark reddish brown.

Frons almost flat on median two-thirds from epistoma to upper level of eyes; surface shining, punctures close, of irregular size, many with a margin finely granulate; median

18.

AREdnson

Fig. 117. Scolytus spp:: 17, 20, 21, quadrispinosus, male, 22, same, female; 18, 23, muticus, female, 24, same, male; 19, rugulosus. (After Blackman 1922:pl. IV.)
line almost impunctate; vestiture of rather abundant, uniformly distributed, moderately long, fine hair, not longer or more abundant at margins.

Pronotum as in mali except punctures distinctly larger.

Elytra as in mali except strial punctures larger, interstriae two to two and one-half times as wide as striae; interstrial punctures about one-fourth as large as those of striae and uniseriate to base.

Sternum 2 vertical on its basal half. Sternum 5 with its apical fourth subvertical, transversely impressed, and modestly pubescent, subinflated just anterior to this point, entirely devoid of a subapical carina.

Female.-Similar to male except frons convex, devoid of granules; sternum 5 coarsely, densely punctured, transverse subapical carina rather strongly elevated.

Distribution.- Illinois to Texas. USA: Illinois: "Southern Illinois." Texas "Tex."
Hosts.- Fagus grandifolia and Celitis sp.
Notes. - The types were not located, although several specimens from the type series were examined. The above treatment was based on specimens labeled "Tex."

## 5. Scolytus quadrispinosus Say

Fig. 117
Scolytus quadrispinosus Say. 1824, J. Acad. Nat. Sci. Philadelphia 3(1):323: (Holotype, male: Missouri; lost)
Scolytus carya Riley, 1867, Prairie Farmer 19:68, 2 Febmary (Syntypes; Princeton, Illmois; not located); LeConte, 1876, Proc. Amer. Philos. Soc. 15:371. Synonymy
Scolytus caryae Walsh, 1867, Practical Ent. 2:58, in latter part of February (Four female syntypes: Princeton, Illinois; not located; synonymy)
Diagnosis.- The sculpture of the male abdomen of this species is unique in the genus. The female is distinguished from the female of muticus Say by the glabrous elytra, by the uniformly short, stout setae on the abdomen, by the coarse strial punctures, and by the serrate posterior margin of the elytra.

Male.- Length 2.9-5.0 mm, 2.0 times as long as wide; color very dark reddish brown.

Frons as in muticus except epistomal process more strongly elevated and marginal pubescence longer and much more abundant.

Pronotum about as in muticus except punctures much finer, glabrous.

Elytra 1.03 times as long as wide, 1.1 times as long as pronotum; about as in fagi Walsh except striae more distinctly impressed, punctures larger, deeper; interstriae one to one and one-half times as wide as striae, punctures very fine, uniseriate; declivital area shorter and steeper than in fagi and posterior margin much more coarsely serrate.

Sternum 2 opaque, strongly concave, its anterior margin strongly produced and with an obtuse median prominence, median line weakly carinate on posterior half. Sternum 3 opaque, armed by three large spines, one on median line, others at lateral margins. Sternum 4 opaque, armed by a median spine. Sternum 5 shorter than 4, a somewhat poorly defined transverse elevation at its middle, its posterior half pubescent.

Female.- Similar to male except frons and abdomen about as in female muticus; abdominal sterna opaque.

Distribution.- Iowa and Quebec to Texas and Georgia.

CANADA: Ontario, Quebec. USA: Alabama, Connecticut, District of Columbia, Georgia, Illinois, Indiana, Lowa, Louisiana, Michigan, Mississippi, Missouri, New Jersey, New York, North Carolina, Ohio, Pennsylvania, South Carolina, Temnessee, Texas, Virginia, West Virginia, Wisconsin.

Hosts. - Carya spp.
Biology.- The limbs and bole are attacked. The female forms the entrance tunnel and a uniramous, longitudinal gallery without a nuptial chamber. Mating takes place either with the male on the bark surface and the female just inside, or with both just inside the burrow (Blackman 1922:45). The males rarely enter the tunnels and, when they do enter, remain for only a brief time. Egg galleries vary from $2-7 \mathrm{~cm}$ in length and contain 20-140 egg niches. Larval mines usually begin in the transverse direction then curve to parallel the grain of the wood during the late instars. When mature, the larvae bore into the outer phloem tissues, where they pupate. Newly emerged adults feed in the bark of twigs before seeking a new host. Two generations occur annually. This is said to be the most destructive insect in hickory.

Notes.- The types of quadrispinosus are lost; however, this species is easily recognized from the original description. My material was compared to that of LeConte, Blackman, etc., and is of the same species.

## 6. Scolytus multistriatus (Marsham) Figs. 118, 119

Ips multistriatus Marsham, 1802, Ent. Britannica, p. 54 (Syntypes?; presumably England; not located) Scolytus flavicormis Chevrolat, 18.38, in GuérinMéneville, Iconographie du règne animal de G. Cuvier 7:181 (not seen); Hagedorn, 1910, Gen. Ins. 4:86. Synonymy
Scolytus ulmi Redtenbacher, 1849, Fauna Austriaca, die Käfer, p. 361 (Syntypes?; presumably Austria; not located); Schedl, 1948, Zlb. Ges. Ent., Monogr. 1:61. Synonymy
Scolytus javanus Chapuis, 1869, Synopsis des Scolytides, p. 56 (Holotype, male; Java; Brussels Mus.); Schedl, 1954, Philippine J. Sci. 83:137. Synonymy Scolytus multistriatus var.? triornatus Eichhoff, 1880, Die Europäischen Borkenkäfer, p. 160 (Syntypes; Thüringen, Germany; not located); Schedl, 1948, Zlb. Ges. Ent., Monogr. I:61. Synonymy
Eccoptogaster orientalis Eggers, 1910, Deutsche Ent. Zeitschr., p. 557 (Lectotype, male, Elisabetpol, Caucasiae rossicae; U.S. Nat. Mus., 60419, designated by Anderson and Anderson, 1971, Smithsonian Contrib. Zool. 94:23); Schedl, 1948, Zlb. Ges. Ent., Monogr. 1:61. Synonymy
Scolytus nodifer Reitter, 1913, Wiener Ent. Zeit. 32(Beiheft); 24 (Holotype, male, Walachia, Romania; Budapest Mus.); Schedl, 1948, Zlb. Ges. Ent., Monogr. 1:61. Synonymy
Eccoptogaster abhorrens Wichmann, 1913, Wiener Ent. Zeit. 32:210 (not seen); Schedl, 1948, Zlb. Ges. Ent., Monogr. 1:61. Synonymy
Eccoptogaster affinis Eggers, 1914, Ent. Blätt. 11:108 (Holotype, male; Mazedonien; U.S. Nat. Mus., 60409); Schedl, 1948, Zlb. Ges. Ent., Monogr. 1:61. Synonymy
Scolytus multistriatus therondi Hoffmann, 1939, Misc. Ent. 11:36 (not seen); Schedl, 1948, Zlb. Ges. Ent., Monogr. 1:61. Synonymy

Scolytus papuanus SchedI, 1936, J. Fed. Malay St. Mus. 18:8 (Syntypes; Kap Koenig Wilhelm, New Guinea; Berlin Zool. Mus.); Schedl, 1962, Ent. Blätt. 58:201. Synonymy
Diagnosis.- This introduced European species is distinguished from other American representatives of the genus by the large median spine on the anterior half of sternum 2 and by the fine tubercles on the posterolateral margins of abdominal sterna 2-4.

Male.- Length $1.9-3.1 \mathrm{~mm}, 2.2$ times as long as wide; color dark reddish brown, elytra often slightly lighter.

Frons feebly concave from eye to eye, from epistoma to vertex; surface rather coarsely aciculate, punctures not clearly defined. Vestiture of fine, rather long, moderately abundant, uniformly distributed hair.

Pronotum 1.0 times as long as wide; outline as in other species; surface brightly shining, punctures moderately coarse, deep, rather close, interspaces averaging about twice diameter of a puncture. Glabrous.

Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; outline as in most other species; striae moderately impressed, interstriae weakly impressed, punctures of striae and interstriae uniseriate, rather small, moderately deep, close, interstrial punctures often slightly smaller than those of striae; surface smooth. Glabrous except for a few setae on declivity. Declivity gradual, rather short; posterior margin smooth.

Fig. 118. Scolytus multistriatus, female: a, protibia; b, antenna; c, male head. (After Kaston 1936:615.)

Sternum 2 subvertical, anterior half on median margin armed by a coarse cylindrical, projecting spine; posterolateral margins of 2-4 each bearing a small, pointed tubercle; occasional males also with small median tubercle on posterior margin of 3 and 4 .

Female.-Similar to male except frons rather strongly convex, with vestiture sparse, very short.

Distribution.- British Columbia and Nova Scotia to California and Florida. Europe and N Asia.

CANADA: Southern Provinces, presumably from British Columbia to Nova Scotia. USA: All states.

Biology.- This species is the principal American vector of the Dutch elm disease fungus, Ceratocystis ulmi; consequently, it is

Fig. 119. Scolytus multistriatus, gallery system. (After Welch, Rankin, and Readio 1945:9.)
the most important insect attacking elms. They overwinter as larvae in the brood tree and emerge as adults in May. Emerging beetles construct feeding tunnels in healthy elm twigs, at which time disease spores are introduced into the living phloem. They then fly to a new host tree to rear their brood. Cut, unthrifty, or diseased trees are selected for attack where uniramous, longitudinal egg galleries are formed by the females. Larval mines radiate from the parental mine along a more or less definite course. Pupation occurs in the bark. From one and one-half (Canada) to three generations (southern U.S.) may occur annually.

Notes.- No attempt was made to locate the types of this introduced species. More than 1,000 specimens from Europe and America were examined.

## 7. Scolytus piceae (Swaine)

Fig. 120
Eccoptogaster piceae Swaine, 1910, Canadian Ent. 42:32 (Lectotype, male; "Ste. Ann's" or Ste. Anne de Bellevue, Quebec; Cornell Univ. Coll., designated by Bright, 1967, Canadian Ent. 99:674)
Diagnosis.- This species is distinguished from all other American species by the position of the spine on abdominal sternum 2.

Male.- Length 2.2-2.8 mm, 2.2 times as long as wide; color very dark reddish brown, pronotum often almost black.

Frons flat to weakly convex to vertex, ascending slightly toward epistomal process; surface shining, moderately aciculate, moderately abundant, fine granules uniformly distributed; vestiture of rather abundant, long hair.

Pronotum as in multistriatus (Marsham) except punctures more widely spaced, varying in size within a series from rather fine to moderately coarse.

Elytral outline about as in multistriatus; striae usually feebly impressed, punctures rather small, moderately impressed; interstriae smooth, shining, about three times as wide as striae, punctures uniseriate, usually smaller than those of striae (strial and interstrial punctures vary within and between series from minute to moderately coarse); posterior margin subserrate.

Sternum 2, subvertical, its basal margin meeting 1 at an obtuse angle; armed on
middle third by a coarse, rather long, conical, median spine, its base remote from both anterior and posterior margins of segment; surface subreticulate, somewhat dull, punctures variable between series, very fine to rather coarse; vestiture of minute, sparse, fine hair.

Female.-Similar to male except frons rather strongly convex, vestiture much less abundant, shorter; spine on sternum 2 distinctly smaller (variable).

Distribution.- Alaska and Nova Scotia to California and New York.

ALASKA: Several localities. CANADA: Alberta, British Columbia, Manitoba, Northwest Territories, Ontario, Quebec. USA: California, Colorado, Idaho, Maine, Massachusetts, Michigan, Montana, New Mexico, New York, North Dakota, Oregon, Utah, South Dakota, Washington, Wisconsin, Wyoming.

Hosts. - Picea spp., rare or accidental in other conifers.

Biology.- Longitudinal, biramous parental galleries are constructed in shaded-out branches of living trees. Larval mines radiate

16
15

17

18

Fig. 120. Scolytus piccae, male: 15, dorsal aspect: 16 , antennal club); 17, caudal aspect; 18, profile of posterior area. (After Edson 1967:40.)
from the parental mine along a directed course.

Notes. - The above treatment was based on the lectotype and on 81 other specimens. Fossil fragments of this species were recovered from prehistoric lake deposits at East Grand Forks, Minnesota, estimated age 10,000 years; at Scarborough, Ontario, estimated age 70,000 years; and from several other dates and localities between these areas.

## 8. Scolytus unispinosus LeConte Fig. 121

Scolytus unispinosus LeConte, 1876, Proc. Amer. Philos. Soc. 15:372 (Lectotype, male; Oregon; Mus. Comp. Zool. 965, present designation) Scolytus sobrinus Blackman, 1934, U.S. Dept. Agric. Tech. Bull. 431:23 (Holotype, male; Kent, Washington; U.S. Nat. Mus., 43840); Wood, 1966, Great Basin Nat. 26:30. Synonymy
Scolytus fiskei Blackman, 1934, U.S. Dept. Agric. Tech. Bull. 431:25 (Holotype, male; Capitan Mts., New Mexico; U.S. Nat. Mus., 43840); Wood, 1977, Great Basin Nat. 37:388. Synonymy
Diagnosis.- This species is distinguished from piceae (Swaine) by the posterior basal margin of the spine on abdominal sternum 2 attaining the posterior margin of the segment, the spine also being slightly, longitudinally compressed in the male; by the reticulate area on and near the posterior margin of the elytra; and by the weakly convex male frons, with the aciculation evidently finer.

Male.- Length $2.0-2.4 \mathrm{~mm}, 2.1$ times as long as wide, color very dark brown, elytra usually slightly lighter.

Frons feebly concave, rather finely aciculate, granules not evident, surface shining; vestiture of rather short, fine, uniformly distributed hair.

Fig. 121. Scolytus unispinosus, male: 25, caudal aspect; 26, profile of posterior area. (After Edson 1967:42.)

Pronotum as in piceae except punctures much finer.

Elytra as in piceae except punctures on declivital area much finer; surface on posterior half of declivital area reticulate (smooth in piceae).

Sternum 2 with anterior margin rounded, not angulate as in piceae, spine laterally compressed, its base extending from posterior margin to middle of segment; surface dull, reticulate; punctures on all sterna very fine.

Female.-Similar to male except frons rather strongly convex, surface feebly aciculate, punctures fine, clearly impressed; spine on sternum 2 greatly reduced (variable), conical, its summit near posterior margin.

Distribution.- British Columbia and Alberta to California and New Mexico.

CANADA: SW Alberta. British Columbia. USA: Arizona, California. Colorado, ldaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, Wyoming.

Host.- Pseudotsuga menziesii, rare or accidental in other conifers.

Biology. - This species attacks the unthrifty tops and limbs of living trees and slash where longitudinal uniramous or biramous parental galleries are formed. Larval mines radiate from the egg gallery along a directed course. Pupation occurs in the phloem. Chamberlin (1958:48) reports two generations annually in Oregon, with flight periods in May and July. One generation apparently is the rule in cooler areas.

Notes.- The above treatment was based on the holotypes of sobrinus and fiskei, on the syntypes of unispinosus, and on 164 other specimens. The species unispinosus was based on two syntypes, only one of which is now in the LeConte Collection. This syntype, labeled "type," is here designated as the lectotype of unispinosus LeConte.

Blackman described sobrinus and fiskei on minor differences in sculpture, which I regard as individual variation. Although there is a slight geographical association with the variation in size and shape of the spine on sternum 1 and, apparently, in the uniramous or biramous parental galleries, both features are variable within a given area. At the present time there is insufficient evidence to warrant the recognition of subspecies.

## 9. Scolytus laricis Blackman

Fig. 122
Scolytus laricis Blackman, 1934, U.S. Dept. Agric. Tech. Bull. 431:24 (Holotype, male; Moscow, Idaho; U.S. Nat. Mus., 43839)

Diagnosis.- This species is distinguished from unispinosus LeConte by the more strongly flattened male frons, by the more coarsely aciculate frons in both sexes, and by the larger spine on the male sternum 2; this spine is also laterally compressed in the female.

Male.- Length $2.4-3.0 \mathrm{~mm}, 2.1$ times as long as wide; color very dark reddish brown, elytra slightly lighter.

Frons as in unispinosus except transversely flat at upper level of eyes, feebly concave below, surface coarsely aciculate, vestiture more abundant.

Pronotum and elytra as in unispinosus except declivital area near posterior margin smooth, without any indication of reticulation. Sternum 2 as in unispinosus except spine much stouter.

Female. - Similar to male except sexes differing as in unispinosus; spine on sternum 2 at least slightly laterally compressed.

Distribution.- British Columbia and Oregon to Montana.

CANADA: British Columbia. USA: N Idaho, W Montana, Oregon, Washington.

Hosts.- Larix occidentalis and L. lyallii.
Biology. - Apparently as in umispinosus.
Notes. - The above treatment was based on the holotype and on 54 other specimens.

## 10. Scolytus scolytus (Fabricius)

Bostrichus scolytus Fabricius, 1775, Systema Entomologiae. p. 59 (types not located)
Scolytus punctatus Müller, 1776, Zoologiae Danicae, 57 (types not located): Goeze, 1777, Ent. Beytr. 1:143. Synomymy

21

Fig. 122. Scolytus laricis, male: 21, caudal aspect: 22, profile of posterior area. (After Edson 1967:41.)

Scolytus niger Geoffroy, 1785, in Fourcroy, Ent. Paris., p. 139 (not located): China, 1962, Bull. Zool. Nomencl. 19:6. Synonymy
Scolytus destructor Olivier, 1795, Entomologie 4(78):1 (Syntypes; Europe; not located); Gyllenhal, 1813. Insecta Svecica Descripta 1(3):347. Synonymy
Scolytus californicus LeConte, 1868, Trans. Amer. Ent. Soc. 2:166 (Holotype, male; California; Mus. Comp. Zool.); Blackman, 1934, U.S. Dept. Agric. Tech. Bull. 431:5. Synonymy
Scolytus destructor var. sulcifrons Rey, 1892, LExchange, p. 20 (a variant form, apparently with no status in nomenclature); Schedl, $194 \dot{8}$. Zlb. Ges. Ent., Monogr. 1:45. Synonymy
Scolytus destructor var. ciliatus Rey, 1892, L'Exchange, p. 30 (a variant form, apparently with no status in nomenclature); Schedl, 1948, Zlb. Ges. Ent., Monogr. 1:45. Synonymy
Scolytus eichhoffi Reitter, 1894, Verh. naturf. Ver. Brünn 33:10 (Holotype, male; Talyschgebirge, am Kaspischen Meere; Budapest Mus.): Schedl, 1948, Zll. Ges. Ent., Monogr. 1:45. Synonymy
Eccoptogaster leonii Eggers, 1908, Nat. Siciliano 20:194 (Lectotype, male; Cerchio, Aquilensi, Italy: U.S. Nat. Mus., 70152, designated by Anderson and Anderson, 1971, Smithsonian Contrib. Zool. 94:17); Schedl, 1948. Zlb. Ges. Ent., Monogr. 1:45. Synonymy
Eccoptogaster triarmatus Eggers, 1912, Ent. Blätt. 8:205 (Holotype, female; origin uncertain, possibly France; U.S. Nat. Mus., 60587); Schedl, 1948. Zlb. Ges. Ent., Monogr. 1:45. Synonymy
Scolytus fuchsi Reitter, 1913, Wiener Ent. Zeit. 32(Beiheft): 15 (Two male syntypes; Russischarmenisches Gebirge, am Alagoes; Budapest Mus.); Schedl, 1948, Zlb. Ges. Ent., Monogr. 1:45. Synonymy
This European species has been introduced on numerous occasions into the United States, but it is not known to be established here. It is distinguished from established and native American species by the large size, by the granular frons, and by the armature of abdominal sterna 3 and 4 as indicated in the above key.

In Europe it is the most serious vector of Dutch elm disease; consequently, its establishment in America would be of immediate concern.

## 11. Scolytus virgatus Bright

Scolytus cirgatus Bright, 1972, Canadian Ent. 104:1490 (Holotype, male; Cerro Potosí, Nuevo León, Mexico; Canadian Nat. Coll.)

Diagnosis.- This species is distinguished from reflexus Blackman by characters of the venter of the abdomen as indicated below.

Male.- Length $3.0-3.5 \mathrm{~mm}, 2.1$ times as long as wide; color almost black.

As in female reflexus except frons less strongly convex (more strongly convex than in male reflexus, but less strongly aciculate), vestiture as in male reflexus; venter resembling female reflexus except posterior margin of segment 1 more angulate, projecting slightly as in female ventralis LeConte, posterior margin of 2 at median line with a feeble, elevated, subtuberculate crest, resembling poorly developed equivalent of structure seen in ventralis; transverse, elevated carina on sternum 5 as in female reflexus.

Female.- Apparently identical to female reflexus except lower frons more evenly convex, epistomal process less conspicuously elevated.

Distribution.- Nuevo León.
MEXICO: Nuevo León: Cerro Potosí, 2-V-71, 2800 m , Pscudotsuga menziesii, D. E. Bright.

Notes. - The above treatment was based on the type series of six specimens.

## 12. Scolytus reflexus Blackman Fig. 123

Scolytus reflexus Blackman, 1934, Dept. Agric. Tech. Bull. 431:13 (Holotype, male; Santa Catalina Mts., Arizona; U.S. Nat. Mus., 43831)
Scolytus wickhami Blackman, 1934, U.S. Dept. Agric. Tech. Bull. 4:31:13 (Holotype, male; Buena Vista, Colorado; U.S. Nat. Mus., 438.32); Wood, 1977. Great Basin Nat. 37:388. Synonymy
Diagnosis.- This species is distinguished from monticolae Swaine by the larger average size, by the marginal notch in line with the apex of elytral interstriae 3, by the much more strongly elevated transverse carina of the male abdominal sternum 5, with its median crest closer to the basal margin than to the apical margin of the segment, and by the longer, coarser hair on abdominal sternum 5.

Male.- Length 2.2-3.5 mm, 2.1 times as long as wide; color very dark brown.

Essentially as in monticolae except as indicated above. Elytral surface sculpture variable, mostly intermediate between monticolae and tsugae.

Female.-Similar to male except sexes differing as in tsugae; abdominal sternum 5 with transverse carina as in tsugae.

Distribution.- Wyoming to Durango and Nuevo León.
USA: Arizona: Kaibab N.F., Santa Catalina Mts. Colorado: Boulder, Buena Vista, Estes Park, Evergreen. New Mexico: Jemez Springs. Wyoming: Saratoga, Clarks Fork Road in Shoshone N.F. MEXICO: Chihuahua: San Juanito. Durango: Durango. Nuevo León: Cerro Potosí.

Host.-Pseudotsuga menziesii.
Biology.- Longitudinal parental tunnels may occur in shaded-out branches of living trees, but there is a great tendency for this species to occur in slash, tops, and the bole of small trees.

Notes.- The above treatment was based on the holotypes of reflexus and wickhami and on 108 other specimens. There appears to be a north-south cline in the intensity of elevation of the male abdominal sternum 5 and in the degree to which it is reflexed cephalad. Some series in the southern half of the range also have longer setae on all abdominal sterna, but this character is inconsistent and apparently without pattern.

## 13. Scolytus monticolae Swaine

Figs. 124, 135
Scolytus monticolue Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):32 (Lectotype, female; Arrowhead, British Columbia; Canadian Nat. Coll., 9240, designated by Bright, 1967, Canadian Ent. 99:674)
Diagnosis.- As indicated in the above key, this species is distinguished from tsugae Swaine by the unimpressed striae, by the more widely spaced strial punctures, by presence of setae on some odd-numbered interstriae (easily abraded), by the lighter color of the elytra, by the host, and by the longitudinal egg gallery.

Male.- Length $2.2-3.0 \mathrm{~mm}, 2.1$ times as long as wide; color very dark brown, elytra distinctly lighter.

Essentially as in tsugae except as noted above.

Female.- Similar to male except sexes differing as in tsugae.

Distribution.- British Columbia to N California and N Utah.

CANADA: British Columbia: Arrowhead, Merritt in Midday Valley, Trinity Valley. USA: California: Angwin, Callistoga. Idaho: Elk River in Clearwater Co., Fernan Lake in Kootenai Co., Franklin Basin in Franklin Co., Malta, St. Maries. Oregon: Paulina. Utah: Logan Canyon, Provo Canyon. Washington: Cliffdell. Wyoming: Cody.

Host.-Pseudotsuga menziesii.
Biology. - Shaded-out branches on living trees are preferred for attack, although they do breed in tops, seedlings, and occasionally in slash. The parental galleries are longitudinal.

Notes.- The above treatment was based on two specimens from Midday Valley that were compared to the lectotype and on 72 other specimens. The exact southern limits of distribution for this species are unknown, apparently because it breeds largely in shadedout branches of living trees and is overlooked by collectors.

## 14. Scolytus tsugae (Swaine)

Fig. 135
Eccoptogaster tsugae Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):32 (Lectotype, female; Glacier, British Columbia; Canadian Nat. Coll., 9239, designated by Bright, 1967, Canadian Ent. 99:674)

Fig. 123. Scolytus reflexus, male: 11, dorsal aspect; 12 , antennal club; 13 , caudal aspect; 14 , profile of posterior area. (After Edson 1967:39.)

Diagnosis.- This species is distinguished by the modestly convex, unarmed abdominal sternum 2, by the emargination on the apical margin of the elytra that is in line with interstriae 3, by the crest of the transverse carina on abdominal sternum 5 being as close to the anterior margin as to the posterior margin of the segment, by the host, and by other characters in the above key.

Male.- Length $2.2-3.5 \mathrm{~mm}, 2.1$ times as long as wide; color dark brown.

Frons broadly, rather weakly convex from epistoma to upper level of eyes; surface moderately aciculate, punctures deep, moderately coarse, rather sparse, uniformly distributed; epistomal process rather strongly elevated on median half; vestiture of coarse, moderately long, uniformly distributed hair.

Pronotum 0.96 times as long as wide; essentially as in piceae (Swaine) except punctures much smaller. Glabrous except near anterior margin.

Fig. 124. Scolytus monticolae, male: 39, dorsal aspect: 40 , antennal club; 41, caudal aspect; 42 , profile of posterior area. (After Edson 1967:46.)

Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; outline as in piceae except posterior margin with a distinct emargination in line with interstriae 3; striae narrowly, distinctly, moderately impressed, punctures, rather coarse, spaced by one to two diameters of a puncture, deep; interstriae about three times as wide as striae, distinctly convex, smooth, shining, punctures fine, shallow, uniseriate. Declivital area with punctures larger and deeper than on dise, confused. Vestiture confined to declivity, of a few stout, interstrial hairs.

Sternum 2 subvertical on basal threefourths, rather weakly convex; surface smooth, shining to opaque, punctures rather coarse, close; vestiture minute. Sternum 5 with transverse carina arcuate, commencing at anterolateral angles, attaining a point slightly behind middle of segment at median line; area posterior to carina rather closely pubescent.

Female.- Similar to male except frons more strongly convex, its vestiture much finer; sternum 2 more evenly convex; carina on sternum 5 much closer to posterior margin than to anterior margin of segment.

Distribution.- British Columbia and E Montana to N California.

CANADA: British Columbia. USA: California: Vista Trail, Yosemite. Idaho: Big Sand Creek and Priest River Expt. For. in Latah Co., Deception Creek in Kootenai Co. Montana: E Montana. Oregon: Crater Lake, Reedport. Washington: Seattle.

Hosts.-Tsuga sp.
Biology.- Shaded-out limbs, slash, and tops of trees are selected for attack. The transverse parental gallery is either mono- or biramous. Larval mines follow a directed course away from the parental system. Pupation occurs in the bark. Apparently only one generation each year occurs in most areas, although this may not be true in warmer areas along the Pacific Coast.

Notes. - The above treatment was based on the lectotype of tsugae and on 81 other specimens. The shining abdominal sterna found universally in specimens from the southeastern parts of the range is gradually replaced by opacity in those of the northwest, commencing with segment 5 and extending cephalad, reaching its greatest intensity in northwestern California. Because
the opaque surface feature could be mechanically peeled from some specimens, its significance is not clear. More information on this species is needed before this problem can be settled.

## 15. Scolytus hermosus Wood

 Fig. 128Scolytus hermosus Wood, 1968, Great Basin Nat. 2S:12 (Holotype, male; 15 km N Tlaxco (Tlaxcala), Puebla, Mexico: Wood Coll.)
Scolytus sylcaticus Bright, 1972, Canadian Ent. 104:1459 Holotype, male; Cerro Potosí, Nuevo León, Mexico: Canadian Nat. Coll.); Wood, 1975. Great Basin Nat. 35:22. Synonymy
Diagnosis. - This species is distinguished from robustus Blackman by the larger size, by the more finely punctured pronotum and elvtra, by the brightly shining, very finely, densely punctured abdominal sterna, and by the somewhat less strongly elevated anterior margin of abdominal sternum 2.

Male.- Length $3.0-3.7 \mathrm{~mm}, 2.1$ times as long as wide: color black with dark reddish brown elytra.

Frons broadly, weakly convex to vertex, with slight transverse impressions just above eyes and just above epistoma; surface shining, rather coarsely punctate-aciculate; vestiture consisting of rather sparse, uniformly distributed, long, dark hair. Antennal club 1.7 times as long as wide; suture 1 distinct.

Pronotum as in robustus except punctures distinctly smaller.

Elytra essentially as in robustus except strial and interstrial punctures distinctly smaller; interstrial punctures minute, distinctly smaller than those of striae; posterior margin finely serrate on median third.

Abdominal sternum 2 with anterior margin about two-thirds as high as in robustus, general contours otherwise similar to that species; surface of sterna 2 to 5 brightly shining, very finely, closely, deeply punctured; each puncture bearing a fine, semirecumbent, short hair about two to three times as long as diameter of a puncture.

Female.- Similar to male except frons much more strongly convex; anterior margin of abdominal sternum 2 weakly elevated, elevation about as high as thick.

Distribution.- Nuevo León to Puebla.
MEXICO: Nuevo León: Cerro Potosí, 3-V-71, 3300 m , Pseudotsuga menziesii, D. E. Bright. Puebla: 18 km N

Tlaxco ( 2 km N state boundary line), 9-Vll-67, 2900 m . No. 182, Abies religiosa, S. L. W'ood.

Host.-Abies religiosa, Pseudotsuga menziesii.

Biology.- Specimens were taken from transverse, biramous parental tumnels in slash larger than 10 cm in diameter.

Notes. - The above treatment was based on the type series of 24 specimens of hermosus and the type series of three specimens of sylvaticus.

## 16. Scolytus robustus Blackman

 Figs. 125, 135Scolytus robustus Blackman, 1934. U.S. Dept. Agric. Tech. Bull. 431:19 Holotype, male; Prescott, Arizona; ('S. Nat. Mus.. 43835)
Diagnosis.- This species is distinguished from hermosus Wood by the smaller size, by the slightly more coarsely punctured pronotum and elytra, by the obscurely reticulate abdominal sterna, and by the more strongly

Fig. 125. Scolytus robustus, male: 47, dorsal aspect; 48, antennal club: 49, caudal aspect; 50 , profile of posterior area. (After Edson 1967:48.)
projecting posterior margin of male sternum 1.

Male.- Length 2.5-3.1 mm, 2.0 times as long as wide; color very dark brown, almost black, elytra often reddish brown.

Frons broadly, feebly convex, deeply, rather coarsely aciculate, punctures obscure; surface shining; epistomal process rather strongly elevated, broadly emarginate; vestiture of fine, rather long, moderately abundant hair.

Pronotum 0.90 times as long as wide; as in tsugae (Swaine).

Elytra 1.1 times as long as wide, 1.4 times as long as pronotum; outline about as in piceae (Swaine) except lateral and posterior margins serrate; striae not impressed, punctures fine; interstriae about three times as wide as striae, smooth, punctures fine, uniseriate. Declivital area longitudinally strigose; posterior margin rugose-reticulate, finely serrate.

Sternum 1 with posterior margin projecting caudad, projection twice as high as thick; 2 vertical, flat, obscurely reticulate, shining, punctures rather coarse, deep, moderately close, vestiture minute; 3-5 of similar surface sculpture.

Female.-Similar to male except frons much more strongly convex, finely aciculate, small punctures clearly impressed, vestiture less abundant, shorter; sternum 1 weakly projecting, 2 weakly convex.

Distribution.- Utah and Colorado to Arizona and New Mexico.

USA: Arizona, Colorado, Nevada, New Mexico, Utah.
Host.- Abies concolor.
Biology.- This species breeds in limbs, tops, and slash. The biramous galleries are most commonly oblique, but may vary from almost transverse to almost longitudinal. The larval mines tend to be longitudinal. Pupation occurs in the cambium area.

Notes.- The above treatment was based on the holotype and on 65 other specimens.

## 17. Scolytus oregoni Blackman

Figs. 126, 135
Scolytus oregoni Blackman, 1934, U.S. Dept. Agric. Tech. Bull. 431:18 (Holotype, male; Ashland, Oregon; U.S. Nat. Mus., 43834)
Diagnosis.- This species is distinguished from robustus Blackman by the reticulate,
much more coarsely punctured abdominal sterna, and, in the male, by the much thicker, less strongly projecting posterior margin of sternum 1.

Male.- Length $2.7-3.3 \mathrm{~mm}, 3.1$ times as long as wide; color dark brown.

Frons, pronotum, and elytra as in robustus except punctures of pronotum and elytra finer; setae on declivital area of elytra much finer.

Sternum 1 with thick posterior margin projecting caudad less than its thickness; 2 vertical on slightly more than anterior half, this area irregularly impressed, usually more strongly impressed on anteromedian portion; sterna 2-5 reticulate, dull, much more finely punctured than in robustus. Vestiture minute.

Female.-Similar to male except frons rather strongly convex, less strongly aciculate, vestiture finer, shorter; sternum 1 projecting only slightly, 2 weakly convex.

Distribution.- Washington(?) to California.

USA: California: Angwin, Fenner Canyon. Oregon: Ashland, Woods. Washington: Seattle.

Hosts.- Pseudotsuga macrocarpa, P. menziesii.

Biology.- This species breeds in limbs, tops, and slash. The longitudinal parental tunnels are biramous. Apparently its flight period is in August and, consequently, it has been largely overlooked by those studying forest insects.

Notes.- The above treatment was based on the holotype and on 21 other specimens. I have seen one specimen labeled Seattle, Washington, but this record should be confirmed by additional collections before it is accepted.

Fig. 126. Scolytus oregoni, male: 45, caudal aspect; 46, profile of posterior area. (After Edson 1967:47.)

## 18. Scolytus praeceps LeConte <br> Figs. 127, 136

Scolytus pracceps LeConte, 1876. Proc. Amer. Philos. Soc. 15:373 (Lectotype, female; Calaveras. California; Mus. Comp. Zool., 967, present designation)
Diagnosis.- This species is distinguished from oregoni Blackman by the smaller size, by the thinner projecting posterior margin of the male abdominal sternum 1, by the more extensively flattened, vertical, male sternum 2, which often has a weak, subcarinate summit at its posteromedian margin, and by the rather stout, almost scalelike, minute setae as on the other abdominal sterna.

Male.- Length 2.0-2.7 mm, 1.9 times as long as wide; color very dark brown, elytra usually slightly lighter.

Frons as in oregoni except very slightly more strongly convex. Pronotum more coarsely punctured than in oregoni, about as in robustus Blackman. Elytra as in oregoni. Sternum 1 as in robustus except usually arising more abruptly from 2 and projecting less strongly. Sternum 2 flat, as in robustus, but often with a feeble median crest at posterior margin, surface reticulate, dull, punctures fine: vestiture on all sterna of minute, stout, almost scalelike setae.

Female.-Similar to male except frons more strongly convex; posterior margin of sternum 1 poorly developed, projecting very slightly.

Distribution.- British Columbia and Idaho to California.
CANADA: British Columbia. USA: California, N Idaho, Oregon. Washington.

Host.-Abies concolor; records from other conifers may be accidental.

Biology.- Apparently as in obelus except that the biramous parental galleries tend to be transverse.

Notes.- The LeConte collection contains six specimens under this name, the first four of which are of this species. The first two are females, and the third and fourth specimens are males; one male has no carina whatever on sternum 2, and the other has a weak carina. The first female is labeled as the type, but has never been so designated; I designate that female as the lectotype of praeceps LeConte. More than 80 specimens were examined.

## 19. Scolytus mundus Wood

Fig. 129
Scolytus mundus Wood, 1968, Great Basin Nat. 28:13 (Holotype, male; 18 km N Tlaxco (Tlaxcala), Puella, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from ventralis LeConte by the larger size, by the more finely punctured elytra, with the surface of the posterior margin smooth and the margin more nearly sinuate, by the subemarginate notch on the posterior margin of the elytra, which is in line with striae 3, by the more coarsely punctured abdominal sterna, and by the larger spine on sternum 2.

Male.- Length 3.6-4.5 mm, 2.3 times as long as wide; color black.

Frons moderately convex with a shallow, rather broad, median impression just above epistoma; surface longitudinally, rather coarsely punctate-aciculate, with a slight median, longitudinal carina on middle third: vestiture of moderately abundant, uniformly distributed, fine, long hair.

Fig. 127. Scolytus praeceps, male with maximum development of spine: 71, dorsal aspect; 72, antennal club): 73, caudal aspect; 74, profile of posterior area. (After Edson 1967:54.)

Pronotum essentially as in ventralis.
Elytra about as in ventralis except punctures smaller, deep; strial and interstrial punctures about equal in size; posterior margin almost smooth, with a weak to moderate notch in line with interstriae 3.

Abdominal sternum 2 abruptly declivous (about a 90 degree angle) but margin not projecting posteriorly; posteromedian margin of 2 armed by a rather large, sharply pointed spine, its apex at suture, its anterior slope descending gradually to about middle of segment much as in obelus Wood; all sterna shining, rather finely, closely, deeply punctured; each puncture bearing a fine, long hair, each hair about equal in length to length of sternum 3.

Female.- Similar to male except frons much more strongly convex, impression obsolete, but with a small median impression on vertex, surface much less strongly aciculate: abdominal sternum 2 more nearly convex, not as steeply declivous, spine rudimentary (not entirely obsolete in any female at hand); abdominal vestiture abraded.

Distribution.- Puebla to Mexico.
MEXICO: Mexico Cerro Tlaloc, 24-IV-80, T. H. Atkinson. Puebla: 18 km N Tlaxco $(2 \mathrm{~km} \mathrm{~N}$ state boundary line), 9-VII-67, 2900 m , No. 182, Abies religiosa, S. L. Wood.

Biology.- Specimens were taken from transverse, biramous parental tunnels in slash larger than 10 cm in diameter.

Notes.- The above treatment was based on the type series of 34 specimens.

9. S. hermosus ơ

## 20. Scolytus aztecus Wood

Scolytus aztecus Wood, 1967, Great Basin Nat. 27:120 (Holotype, female: 43 km or 27 miles E Morelia, Michoacán, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from mundus Wood by the very large size and by other characters summarized in the above key.

Female.- Length 4.5-5.3 mm, 2.3 times as long as wide; color very dark brown, elytra reddish brown.

Frons convex, transversely impressed just above epistoma, a slight median impression at vertex; surface shining, punctures small, rather close, substrigose above; epistoma with a distinctly elevated, dorsally arched ridge above epistomal brush, its lateral extremities blending into a marginal callus; vestiture short, sparse, inconspicuous.

Pronotum 1.03 times as long as wide; widest just behind middle, sides very weakly arcuate, not converging until anterior third, rather strongly constricted at sides just before anterior margin, anterior margin broadly, very feebly emarginate; surface smooth, shining, punctures fine, deep on disc, about twice as large in lateral areas; vestiture confined to lateral areas.

Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two thirds, then converging very slightly to rather abrupt posterolateral angles; median half of posterior outline (of apical margin) occupied by two pairs of

10. S. mundus ơ

Fig. 128-129. Scolytus spp., males: 128. hermosus; 129. mundus. (After Wood 1968:12.)
broad serrations, each serration half as long as wide; striae not impressed, punctures small, deep, regular; interstriae about three to four times as wide as striae, almost flat, shining, punctures moderately large, deep, uniseriate except confused on 2; declivity descending slightly; glabrous, except more coarsely punctured, the feeble, carinate elevation at posterior margin of sternum 2 present on all four specimens.

Distribution.- Michoacán.
Mexico: Michoacán: 43 km ( 27 miles) E Morelia, 14-V1-65, 26i(0) m, No. 52, Abics religiosa, S. L. Wood.

Biology.- Specimens were taken from transverse biramous parental galleries in the bole of a standing tree 60 cm in diameter.

Notes.- The above treatment was based on the type series of four specimens.

## 21. Scolytus opacus Blackman <br> Figs. 130, 135, 136

Scolytus oparus Blackman, 1934, L'S. Dept. Agric. Tech. Bull. $431: 20$ Holotype, male; Ouray, Colorado; U.S. Nat. Mus., 4.38.36)
Scolytus abietis Blackman, 1934, U.S. Dept. Agric. Tech. Bull. 431:21 (Holotype, male; Sandpoint. Idaho: U.S. Nat. Mus., 43837); Wood, 1977, Creat Basin Nat. 37:388. Synonymy
Diagnosis.- This species is distinguished from other species in the genus by the median, male spine on sternum 2 that increases in height from the posterior margin to a point slightly anterior to the middle of the segment, where it terminates abruptly, and by the more strongly produced posterior margin of the female sternum 1 .

Male.- Length 2.0-2.6 mm, 2.0 times as long as wide; color very dark brown, elytra slightly lighter.

Frons, pronotum, and elytra as in praeceps LeConte.

Sternum 2 similar to pracceps except anterior margin more evenly arcuate, spine considerably larger, its crest begimning at posteromedian margin, rising to a summit about two-thirds of segment length from posterior margin, its shape geographically variable; surface dull, reticulate, apparently more sparsely punctured than in praeceps. Other sterna as in pracceps.

Female.-As in female praeceps except posterior margin of sternum 1 more strongly produced, projection at least as high as thick (less than half as high as thick in praeceps).

Distribution.- Oregon and Montana to Califormia and Colorado.
USA: N Arizona, N California, Colorado, Idaho, Montana. Oregon. Utah, Washington, Wyoming,

Hosts.-Abies concolor, A. grandis, A. lasiocarpa, Picea engelmannii, Tsuga sp.

Biology.- This species apparently prefers small branches and tops of weakened, broken, or cut material. The biramous parental galleries vary from oblique to transverse.

Notes. - The above treatment was based on the holotypes of opacus and abietis and on 69 other specimens. Specimens from the Pacific Coast states and northern Idaho have a slightly smaller spine on the male sternum 2, the summit more narrowly rounded and the crest acute, and the vertex of the head more strongly convex. In some male specimens from the southern Rocky Mountain area the spine on sternum 2 may have the crest flattened or sulcate, as well as the opposite extremes of the other characters mentioned above. However, these features appear to intergrade over a broad area to such an extent that I camnot justify the continued recognition of two names for this taxon.

## 22. Scolytus ventralis LeConte <br> Figs. 131, 136

Scolytus ventralis LeConte, 1868, Trans. Amer. Ent. Soc. 2:167 (Lectotype, male, Washington Territory; Mus. Comp. Zool., 970, present designation)
Diagnosis.- This species is distinguished from all preceding species by the presence of a small, definite, carinate, median tubercle at the posterior margin of male sternum 2 (this elevation is more poorly developed in the female) and by the vertical sternum 2 , with the posterior margin of sternum 1 projecting only feebly in the male, not projecting in the female.

Fig. 130. Scolytus opacus, male: 57, caudal aspect: 58. profile of posterior area. (After Edson 1967:50.)

Male.- Length 2.5-3.8 mm, 2.0 times as long as wide; color very dark brown, elytra usually lighter.

Frons broadly convex, slight transverse impressions at vertex and just above epistoma; epistomal process distinctly elevated; surface shining, rather coarsely aciculate, as in oregoni Blackman; vestiture uniformly distributed, of rather short, fine hair.

Pronotum 0.90 times as long as wide; as in allied species, punctures slightly larger than in oregoni, separated by about two to four times diameter of a puncture. Glabrous except at margins.

Elytra as in oregoni.
Sternum 1 with posterior margin projecting less than half its thickness, 2 vertical, feebly convex, median area at posterior margin slightly elevated, weakly tuberculate, surface dull, obscurely reticulate in some areas, punctures moderately coarse, rather deep, spaced by about two to four diameters of a puncture. Vestiture of very minute, fine hair.

Female.-Similar to male except frons more strongly convex, more finely pubescent; sternum 1 with posterior margin much less strongly projecting, sternum 2 more feebly elevated at median line on posterior margin and usually without a tubercle.

Distribution.- British Columbia and Montana to California and New Mexico.
CANADA: British Columbia. USA: Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, Wyoming.

Hosts.- Abies concolor, A. grandis, A. magnifica, probably accidental in other conifers.

Biology.- This species infests the bole, tops, and slash larger than 10 cm in diameter. Under certain circumstances it evidently is capable of killing healthy trees. The parental
tunnels are biramous and transverse; the larval mines are longitudinal. One generation occurs annually. Details of the life history are reported by Ashraf and Berryman (1969).

Notes.- This species was based on two syntypes, only one of which, a male, remains in the LeConte collection. This male is here designated as the lectotype of ventralis LeConte. The above treatment was based on the lectotype and on 134 other specimens.

The abdominal sterna of specimens from the Pacific Coast are more finely, less deeply impressed than those from inland areas; however, the difference does not appear to be of sufficient magnitude to warrant taxonomic distinction.

## 23. Scolytus obelus Wood <br> Figs. 132, 1.36

Scolytus obelus Wood, 1962. Great Basin Nat. 22:81 (Holotype, male; Payson Canyon, Utah; Wood Coll.)
$\mathrm{D}_{\text {Iagnosis. }}$ - This species is distinguished from praeceps LeConte by the much more finely aciculate frons and by the more strongly concave male sternum 5, which is subshining and armed by a conspicuous median denticle at its posterior margin.

Male.- Length $2.0-2.4 \mathrm{~mm}, 2.0$ times as long as wide; color very dark brown, elytra usually lighter.

Frons as in praeceps except much more finely aciculate. Pronotum and elytra as in praeceps.

Sternum 1 with posterior margin more strongly produced than in praeceps, 2 more strongly concave, subshining, punctures distinctly larger, carinate on posterior fourth of median line, carina ending at margin of segment in a moderate to very strong denticle (variable). Vestiture minute, hairlike.

Fig. 131. Scolytus ventralis, male: 65, caudal aspect; 66, profile of posterior area. (After Edson 1967:52.)

Fig. 132. Scolytus obelus, male: 77, caudal aspect; 78, profile of posterior area. (After Edson 1967:55.)

Female.- Similar to male except frons more strongly convex; sternum 1 with posterior margin projecting slightly more than in female praeceps; sternum 2 weakly carinate on median line at posterior margin.

Distribution.- Nevada and Colorado to Arizona and New Mexico.
USA: N Arizona, Colorado, w Nevada (Baker), New Mexico, Utah.
Host.-Abies concolor.
Biology.- Specimens were taken from diagonal, biramous parental galleries in limbs, tops, and slash $5-10 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the type series of 15 specimens and on 26 other specimens.

## 24. Scolytus subscaber LeConte

 Figs. 133, 136Scolytus subscaber LeConte, 1876, Proc. Amer. Philos. Soc. 15:373 (Lectotype, female; Vancouver, British Columbia; Mus. Comp. Zool., 968, present designation)
Diagnosis.- This species is distinguished from praeceps LeConte by the much larger size, the flattened male frons, the very finely punctured pronotum, and the much more strongly concave male sternum 2.

Male.- Length 2.9-4.4 mm, 2.0 times as long as wide; color very dark brown, elytra lighter.

Frons flat to feebly impressed from epistoma to vertex, rather finely aciculate; vestiture fine, long, moderately abundant.

Pronotum as in praeceps except much more finely punctured.

Elytra as in praeceps except rather obscurely reticulate to base.

Sternum 2 about as in obelus Wood except surface subreticulate, punctures minute, carina and tubercle at posterior margin rather poorly developed.

Fig. 133. Scolytus subscaber, male: 69, caudal aspect; 70, profile of posterior area. (After Edson 1967:53.)

Female.- Similar to male except frons strongly convex; anterior margin of each interstrial puncture finely crenulate; sternum 2 as in female ventralis LeConte.

Distribution.- British Columbia to California.

CANADA: British Columbia. USA: California, N Idaho, Oregon, Washington.

Hosts.- Abies concolor, A. grandis, A. magnifica.

Biology.- This species breeds in the shaded-out limbs and tops of overmature trees. It is virtually unknown in slash. The distinctive parental galleries form a somewhat rounded E-shape. Larval mines radiate in all directions and do not score the wood until almost mature.

Notes.- The above treatment was based on the first two female syntypes in the LeConte Collection; the third syntype is of ventralis LeConte. I here designate the first syntype as the lectotype of subscaber. Thirtyone other specimens were also examined.

## 25. Scolytus dentatus Bright <br> Figs. 134, 1.35

Scolytus dentatus Bright, 1964, Pan-Pacific Ent. 10:167 (Holotype, male; Cone Peak, Monterey Co., California; California Acad. Sci.)
Diagnosis.- This species is distinguished from subscaber LeConte by the more strongly convex male frons, by the presence of a median spine on male sternum 4, and by the normal, unarmed female interstrial punctures.

Male.- Length 3.2-3.8 mm, 1.9 times as long as wide; color very dark brown to almost black, elytra dark reddish brown.

Frons as in subscaber except feebly convex on lower half, more strongly convex above, vestiture slightly coarser, longer.

Fig. 134. Scolytus dentatus, male: 53, caudal aspect: 54, profile of posterior area. (After Edson 1967:49.)

Pronotum and elytra similar to subscaber except pronotal punctures averaging slightly larger; elytra with discal surface smooth, posterior margin more strongly serrate.

Sterna as in subscaber except more coarsely punctured; sternum 4 armed by a coarse, median spine, sterna 2 and 3 with a small, median, subtuberculate elevation at posterior margin.

Female.-Sinilar to male except frons strongly convex; sterna about as in subscaber except more coarsely punctured, and posterior margin of 1 projecting slightly.

Distribution.-California.
USA: California: Cone Peak, Monterey Co., 29-VI-63. Abics bractecta, C. J. Wray.

Biology.- Specimens were taken from longitudinal, biramous galleries in the limbs and bole of a dying tree.

Notes.- The above treatment was based on the holotype and on more than 40 paratypes.

Fig. 135. Scolytus spp., gallery systems: 85, tsugae; 86, monticolae; 87, oregoni; 88, robustus; 89, dentatus; 90, opacus. (After Edson 1967:57.)

## 26. Scolytus costellatus Chapuis

Scolytus costellatus Chapuis, 1869, Synopsis des Scolytides, p. 58 (Holotype, female; Nova-Fribourg, Brazil; Brussels Mus.)
Diagnosis.- This species is distinguished by characters presented in the above key and by the unique frontal, elytral, and abdominal characters.

Male.- Length 3.2-3.9 mm, 1.8 times as long as wide; color black.

Frons flat from eye to eye, from epistoma to vertex, epistoma rather deeply emarginate; surface shining, rather finely aciculate over entire surface; vestiture fine, moderately abundant, rather long.

Pronotum 0.96 times as long as wide; basal margin conspicuously bisinuate; sides widest slightly behind middle, moderately arcuate on basal two-thirds, then rather strongly converging to broadly rounded anterior margin; surface brightly shining, with numerous

Fig. 136. Scolytus spp., gallery systems: 91, opacus; 92, ventralis; 93, subscaber; 94, pracceps; 95, obelus. (After Edson 1967:58.)
minute points, punctures fine on disc, becoming rather coarse laterally; surface longitudinally etched in lateral areas. Glabrous except at margins.

Elytra 0.88 times as long as wide, 0.94 times as long as pronotum; scutellum absent; striae and interstriae strongly, narrowly, equally impressed, interspaces as wide as grooves, smooth and shining, strial and interstrial punctures fine, distinctly impressed; approximately alternate interstrial punctures each bearing a rather stout, short, dark hair; posterior margin smooth.

Junction of sterna 1 and 2 with an abruptly elevated, strongly arcuate costa on median two-thirds extending from anterior margin at median line to middle of segment at its lateral extremities; surface of 2 smooth, shining, punctures coarse, rather close, their interiors reticulate and often with a small granule at their centers; other sterna more finely punctured. Vestiture of erect, stout, rather short hair.

Female.- Similar to male except frons weakly convex above, vestiture less abundant; elytral punctures evidently slightly larger; junction between sterna 1 and 2 rounded, costa absent, anterior third of sternum 2 with a low, rounded median elevation half as high as wide, its summit punctured.

Distribution.- Costa Rica to Brazil.
COSTA RICA: Guápiles, Limón, 22-V1I-66, 100 m , No. 107, woody vine, S. L. Wood; Turrialba, Cartago, 9-III-64, 700 m , No. 468 , woody vine, S. L. Wood. OTHER COUNTRIES: Brazil, Venezuela.

Notes.- The above treatment was based on the holotype and on 84 other specimens.

## 27. Scolytus cristatus Wood

Fig. I37
Scolytus cristatus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 12$ (Holotype, male; Lower Río Tempisque, Guanacaste, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from other American species by the convex, finely aciculate frons in both sexes, with a median subcarinate ridge, and by the low carina arising from the anterior two-thirds of sternum 2.

Male.- Length $2.3-2.7 \mathrm{~mm}, 2.0$ times as long as wide; color dark reddish brown.

Frons convex, somewhat flattened below; surface convergently strigose, grooves usually
wider than ridges, median ridge higher, subcarinate, extending from epistomal margin almost to upper level of eyes; vestiture fine, long, rather abundant, uniformly distributed.

Pronotum very slightly wider than long; widest on basal third, sides moderately arcuate and converging slightly to constriction just behind broadly rounded anterior margin; surface smooth, shining, with some very minute points and rather widely separated, moderately small, deep, oval punctures, punctures larger in lateral areas and in front; glabrous.

Elytra 1.1 times as long as wide, 1.2 times as long as pronotum; striae and interstriae strongly, equally impressed, punctures moderately large, shallow, ridges between rows of punctures smooth, shining, convex, almost as wide as grooves; declivity descending slightly; a few scattered, slender scales on declivity. Venter with sternum 2 ascending abruptly, not sharply, armed by a median, laterally compressed, rather high elevation extending from near anterior margin of segment two-thirds of its length, highest point on elevation near its posterior limits; sternum 2 very coarsely, shallowly punctured, surface within each puncture reticulate, interspaces subreticulate; sternum 3 with one row of punctures, 4 and 5 not clearly punctured, dull.

Female.- Similar to male except frons subglabrous; carinate armature of sternum 2 not as high, occupying middle third of length of segment.

Fig. 137. Scolytus cristatus, male: posterolateral aspect of abdomen. (After Wood 1969:13.)

Distribution.- Jalisco to Venezuela.
MEXICO: Colima, Jalisco. COSTA RICA: Cañas and Río Tempisque in Guanacaste. OTHER COUNTRIES: Venezuela.

Host.- Woody vine.
Biology.- This species was taken from transverse, biramous parental tunnels in recently cut woody vines (lianas).

Notes.- The above treatment was based on the type series of 31 specimens and on 47 other specimens.

## 28. Scolytus nodatus Wood Fig. 138

Scolytus nodatus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):12 (Holotype, male: Santa Ana, San José, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from other American members of the genus by the armature of the male abdomen as described below.

Male.- Length 3.1-3.8 mm, 2.0 times as long as wide; color dark brown, anterior margin of thorax and bases and apices of elytra may be reddish brown.

Frons weakly convex; surface coarsely, somewhat convergently strigose toward
shallowly, broadly emarginate epistomal margin; punctures not evident; vestiture consisting of fine, rather long, moderately abundant hair. Eye emarginate; very finely granulate. Antennal club 2.0 times as long as wide; sutures not evident, very finely, closely pubescent.

Pronotum equal in length and width; widest at base, sides moderately arcuate and converging to distinct constriction just behind broadly rounded anterior margin; surface smooth, brightly shining, punctures rather small, deep, oval, larger in lateral and anterior areas; glabrous on disc, sparse hair at sides and in front.

Elytra 1.1 times as long as wide, 1.1 times as long as pronotum; sides straight and parallel on basal half, converging slightly behind to broadly rounded posterolateral angles, almost straight on median half; posterior margin smooth, striae and interstriae moderately impressed, punctures small, rather deep, those of striae very slightly larger; elytra descending very slightly near posterior margin; vestiture confined to scutellar impression. Sternum 2 ascending sharply, margin not

Fig. 138. Scolytus nodatus: male, left and below; female, right. (After Wood 1969:12.)
produced, armed by a laterally compressed, median spine, its base extending from anterior margin to middle of segment, longitudinal length of base and height of spine about equal; sternum 4 armed by a large, rounded tubercle, 2 and 3 each armed at lateral margins by a pair of small teeth; surface finely, obscurely punctured, dull except anterior half of 2 shining; pubescence sparse, hairlike.

Female.-Similar to male except frons more nearly flat; all abdominal sterna unarmed.
Distribution.- Costa Rica to Panama.
COSTA RICA: Santa Ana, San José, 8-XI-63, 1300 m , No. 254, tree limb, S. L. Wood. PANAMA: Ft. Clayton, Canal Zone, 22-XII-63, 30 m , No. 328, woody vine, S. L. Wood.

Brology.- The Panama series made longitudinal, biramous parental galleries in a large, spiny vine. The Costa Rica specimens apparently were estivating in shallow tunnels in the outer phloem tissues.

Notes.- The above treatment was based on the type series of 25 specimens.

## 29. Scolytus propinquus Blandford

Scolytus propinquus Blandford, 1896, Biol. Centr. Amer., Coleopt. $4(6): 121$ (Syntypes; Mexico, Guatemala, and Cuba; British Mus. Nat. Hist.)
Scolytus penicillus Schedl, 1973, Papeis Avulosos Zool. 26:165 (Holotype, male; Veracruz, Mexico: Schedl Coll.): Wood, 1977. Great Basin Nat. 37:210. Synonymy
Diagnosis.- This species is distinguished from dimidiatus Chapuis by the very different frons and abdominal sterna in both sexes as described below.

Male.- Length 2.4-3.6 mm, 1.8 times as long as wide; color very dark brown, almost black.

Frons almost flat from epistoma to well above eyes, a slight, transverse impression above epistoma; a stout, moderately large, conical, median elevation slightly below middle; surface obscurely reticulate, punctures fine, not close, longitudinally elongate; vestiture confined to lateral margins, consisting of a dense row of long hair from near base of mandible to slightly above upper level of eyes, setae reduced in size and number on vertex.

Pronotum and elytra about as in dimidiatus.

Sterna as in dimidiatus except anterior margin of 2 very weakly produced; vestiture of very abundant, short, stout (somewhat scalelike) setae; a conspicuous tuft of long hair immediately posterior to spine on 2 as in dimidiatus.

Posterior face of metatibia with a conspicuous brush of very long hair.

Female.- Similar to male except frons shallowly, broadly concave from epistoma almost to upper level of eyes, obscurely reticulate, with dense, deep, rather fine punctures, vestiture uniformly distributed throughout impressed area, of very long, fine hair; sterna with longer, finer setae, 2 unarmed, subvertical, its anterior margin not projecting, tuft of hair absent.

Distribution.- Nayarit and Veracruz to Costa Rica.

MEXICO: Chihuahua: Rio Urique, 1-I-80, L. Kirkendall. Nayarit: 8 km N Rosamorada, 15-Vil- $65,100 \mathrm{~m}$, No. 251, tree limb, No. 249, Inga paterno, S. L. Wood. Veracruz: 5 km W' Jáltipan, 25-V1-67, No. 99, tree limbs, S. L. Wood; 24 km W Veracruz, $30-\mathrm{VI}-53$, tree limbs, S. L. Wood. COSTA RICA: Cañas, Guanacaste, 13-VII-56, 50 m, No. 136. leguminous tree, S. L. Wood.

Hosts.- Inga paterno, etc.
Biology.- This species is bigamous; two females are normally associated with each male. Transverse, biramous parental galleries are cut in limbs and boles larger than 5 cm in diameter.

Notes.- The above treatment was based on Blandford's three syntypes and on 105 other specimens.

## 30. Scolytus dimidiatus Chapuis <br> Fig. 139

Scolytus dimidiatus Chapuis, 1869, Symopsis des Scolytides, p. 57 (Syntypes: Toxpam, Cuba; Brussels Mus.)
Diagnosis.- This species is distinguished from torulus Wood as described below.

Male.- Length 2.1-3.2 mm, 1.8 times as long as wide; color very dark brown, almost black.

Frons almost flat above upper level of ocular emargination, this area minutely reticulate, with a few rather widely spaced, fine punctures; lower third strongly, transversely impressed, subconcave on its median third; a rather strongly developed, transverse elevation on median fifth immediately above impressed area; transverse axis of elevation
about twice as great as its longitudinal axis; vestiture confined to lateral margins, consisting of a dense row of very long, dark hair from near base of mandible to upper level of eye.

Pronotum 0.98 times as long as wide; outline as in allied species; punctures fine on disc, becoming moderately coarse in lateral areas.

Elytra 0.99 times as long as wide, 1.0 times as long as pronotum; outline as in costellatus Chapuis; striae feebly impressed, punctures rather small, spaced by more than diameter of a puncture; interstriae smooth, shining, three times as wide as striae, punctures very fine, uniseriate. Vestiture of a few long, stout setae on declivity.

Sternum 2 with basal two-thirds vertical, flat, anterior margin subangulate, not projecting, armed on anterior third by a coarse, median, subconical spine; surface subreticulate, dull, punctures rather fine, moderately deep; surface of sterna 3-5 similar; vestiture of rather short, stout, moderately sparse setae; sternum 2 with a conspicuous tuft of long hair immediately posterior to spine.

Female.-Similar to male except frons weakly concave from epistoma to vertex, reticulate, median half with coarse, longitudinal striations, margins on upper half bearing
a dense row of very long hair, tips of some attaining mandibles; sternum 2 weakly convex, spine slightly smaller, tuft of hair absent.

Distribution.- Veracruz and Cuba to Venezuela.

MEXICO: Veracruz: 5 km W Jaltipan, $25-\mathrm{VI}-67,50$ m, No. 99; tree limbs. S. L. Wood; 24 km W Veracruz, 30-VI-53. tree limbs. S. L. Wood. COSTA RICA: San Ignacio de Acosta, San José, 5-VII-63, 1500 m, No. 29, fence post. S. L. Wood; Santa Ana, San José, 4-X-63, 1300 m , No. 320 , tree bole, S. L. Wood. OTHER COUNTRIES: Venezuela (in Lonchocarpus margaritensis).

Biology. - This species is normally bigamous, with two females associated with each male. It attacks the limbs and boles of recently cut or unthrifty trees, apparently including a rather broad spectrum of host species. The biramous parental galleries are transverse.

Notes.- The above treatment was based on the Chapuis syntypes and on 283 other specimens.

## 31. Scolytus incognitus Eggers

Scolytus incognitus Eggers. 1951, Ent. Blätt. 45-46:154 (Holotype, female; "Mexico"; deposited in but not now in Eggers Collection, presumably on loan to Schedl)
Diagnosis.- This species differs from nevermanni Schedl only by the sculpture and ornamentation of the frons and, in all probability, is the female of that species. It is

Fig. 139. Scolytus dimidiatus, head and abdomen: A, B, male; C, D. female.
distinguished from dimidiatus Chapuis in details of sculpture as noted below.

Female.- Length $1.4 \mathrm{~mm}, 2.2$ times as long as wide; callow cotype yellowish brown.

Frons about as in dimidiatus except upper areas very obscurely subaciculate, a distinct median callus in position of nevermanni elevation; lateral areas adjacent to dorsomedian margin of eye abruptly, more strongly impressed; vestiture confined to margins, hair on lateral margins below eye longer and slightly more abundant than in dimidiatus, hair above eyes much shorter and less abundant than in dimidiatus, with tips of longest setae reaching slightly below middle of frons.

Pronotum, elytra, and abdominal sterna as in nevermanni.

Distribution.- "Mexico."
MEXICO: "Mexico, ded. 30-VI-1897, C. Höge."
Notes.- The above treatment was based on a male in the Schedl collection bearing five labels: (1) Scolytus incognitus n. sp. ot type, Eggers 1925; (2) of ; (3) the locality record quoted above; (4) cotype; (5) $\circ$. The last label was added by Schedl. The first label suggests that this specimen is the holotype although label four places doubt on such a conclusion. This species is not represented in the Eggers collection, although the type and only cotype were deposited there. Schedl (1979:123) lists both type and cotype as being in his collection.

## 32. Scolytus nevermanni Schedl

Scolytus nevermanni Schedl, 1935, Stylops 4:272 (Lectotype, male; Hamburgfarm on Rio Reventazón, Ebene Limón, Costa Rica; Schedl Coll., present designation)
Diagnosis.- This species is distinguished from proximus Chapuis by the larger size, by the more coarsely sculptured frons, by the slightly smaller pronotal and elytral punctures, and by the much more slender elytral scales.

Male.- Length about 3.4 mm , about 2.0 times as long as wide (slightly crushed); color very dark brown.

Frons as in proximus except punctures slightly larger, upper half more strongly subaciculate; median elevation positioned as in proximus but higher, slightly wider, its dorsal face subconcave; vestiture finer, slightly less abundant.

Pronotum as in proximus except punctures averaging slightly smaller.

Elytra as in proximus except strial and interstrial punctures on basal two-thirds much finer; interstrial scales similar but more slender and evidently slightly longer (mostly abraded). Abdominal sterna evidently as in proximus (partly obscured by debris).

Distribution.- Costa Rica.
COSTA RICA: Hamburgfarm on Río Reventazón, Limón, 3-XIl-24, Sapium, F. Nevermann; Bananito, Limon.

Notes.- The above treatment was based on the specimen referred to by Schedl as the female; actually, it is a male. The specimen is here designated as the lectotype of this species.

## 33. Scolytus marginatus Chapuis

Scolytus marginatus Chapuis, 1869. Synopsis des Scolytides, p. 56 (Holotype, female; Yucatán: Brussels Mus.)
Diagnosis.- This species is distinguished from torulus Wood by the more strongly convex frons, with the surface smooth except for weak reticulation near the elevation, by the larger frontal elevation, and by the obscure to absent impressed points on the pronotum.

Female.- Size and proportions as in torulus; elytral punctures apparently average smaller; distinguished from torulus as indicated in the above diagnosis.

Distribution.- Yucatán.
MExiCO: Yucatán, Deyr.
Notes.- The above treatment was based on the holotype.

## 34. Scolytus torulus Wood

Scolytus torulus Wood. 1975. Great Basin Nat. 35:25 (Holotype. male: Rincón de Osa, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from dimidiatus Chapuis by the smaller average size, by the subvertical, somewhat convex abdominal sternum 2, by the absence of a tuft of hair on sternum 2 immediately posterior to the spine, by the very different male frons, and by other characters described below.

Male.- Length $2.0-2.4 \mathrm{~mm}, 2.1$ times as long as wide; color very dark brown to black, elytra slightly lighter.

Frons rather weakly convex above, a distinct, moderately deep, transverse impression just above epistoma, deepest in median area, a distinct but weak, rounded, median elevation immediately above impressed area; surface strongly reticulate above, more shining and obscurely aciculate in impressed area, punctures fine, rather deep, sparse in median area, more numerous laterally; vestiture of fine hair on margins and impressed area, a few of them rather long.

Pronotum as in dimidiatus except punctures in lateral areas considerably larger.

Elytra 1.1 times as long as wide, 1.2 times as long as pronotum; surface about as in dimidiatus but much more finely punctured, a few to many longitudinal lines or striations sometimes present. Sparse setae shorter and much stouter than in dimidiatus.

Sternum 2 subvertical, moderately convex, spine similar to dimidiatus but smaller; surface dull, very coarsely, deeply, closely punctured; sterna 3-5 similar but more finely punctured; vestiture of very fine, short hair, without a specialized tuft posterior to spine on 2.

Female.-Similar to male except frons without impression or elevation, not strigose, vestiture similar to but finer and about onethird as abundant as in dimidiatus female; spine on sternum 2 about half as large as in male.

Distribution.- Costa Rica.
COSTA RICA: Rincón de Osa, Puntarenas, 11-VIII$66,30 \mathrm{~m}$, No. 72 , leguminous tree, S. L. Wood.

Notes.- The above treatment was based on the type series of 12 specimens.

## 35. Scolytus laetus Wood

Scolytus laetus Wood, 1975, Great Basin Nat. 35:25 (Holotype, male; 48 km or 30 miles N Rosamorada, Nayarit, Mexico: Wood Coll.)
Diagnosis.- This species is distinguished from torulus Wood by the flattened sternum 2 , which is much more finely, sparsely punctured, with longer, more abundant hair, and by characters of the frons described below.

Male.- Length $2.4-2.5 \mathrm{~mm}, 2.4$ times as long as wide; color very dark brown.

Frons as in torulus except elevation wider, area above elevation more distinctly, more broadly impressed, vestiture on lateral margins more abundant, much longer.

Pronotum and elytra as in torulus.
Sternum 2 vertical, almost flat, surface dull, punctures small, not clearly evident, spines as in torulus, vestiture much longer, some setae as long as spine.

Female.- Similar to male except frons as in torulus but with vestiture slightly more abundant and longer, particularly in lower areas; sternum 2 unarmed, spine absent, vestiture finer, more abundant.

Distribution.- Nayarit.
MEXICO: Nayarit: 48 km N Rosamorada, I5-VII-65, 100 m , No. 257, Inga paterno, S. L. Wood.

Biology.- Specimens were mixed with a series of propinquus Blandford and, presumably, have similar habits.

Notes. - The above treatment was based on the type series of five specimens.

# Tribe CTENOPHORINI 

Ctenophoridae Chapuis, 1869, Synopsis des Scolytides, p. 49 (Type-genus: Scolytodes Ferrari, $1867=$ Ctenophorus Chapuis, 1869)
Problechilidae Eichhoff, 1878, preprint of Mem. Soc. Roy. Sci. Liége (2)8:298 (Type-genus: Gymnochilus Eichhoff, $1867=$ Problechilus Eichhoff, 1878)
Hexacolidae Eichhoff, 1878, preprint of Mem. Soc. Roy. Sci. Liége (2)8:306 (Type-genus: Hexacolus Eichhoff, 1868 $=$ Scolytodes Ferrari, 1867)

Anatomical features.- The frons is usually sexually dimorphic, with the male impressed and the female flat to convex in Pycnarthrum and Gymnochilus; sexual differences are not readily apparent in Microborus; the male is convex and the female variously sculptured' and ornamented in Scolytodes. In addition, the posterior face of the head is truncate, the eye is entire to sinuate, the antennal funicle is $6-7$-segmented, the club is usually marked by sutures, the pronotum is armed or not, its lateral margins are costate, the procoxae are rather widely separated, the protibiae have one or more nonsocketed denticles on the lateral margin, with the apical one extending beyond the level of the tarsal insertion, and the pleural suture is essentially as in the Scolytini.

Biological features.- All species are monogamous except for a few Scolytodes, and all except one (Scolytodes multistriatus Wood is xylophagous) are phloeophagous. The parental tunnels vary in Scolytodes from a simple cave to an irregular or elongate cavity; in Pycnarthrum and Gymnochilus they are biramous, and in Microborus an indefinite, nondirectional tunnel is excavated after entry is made into the host through the tunnel of another insect. The eggs may be scattered loosely or placed in crude niches in Scolytodes; in Pycnarthrum and Gymnochilus definite egg niches are formed. The larvae usually feed communally and extend the parental galleries in Scolytodes; in Pycnarthrum and Gymnochilus they are individual and follow a somewhat definite direction, but commonly cross one another. Symbiotic relationships with fungi are not known.

Taxonomy.- This tribe is restricted to the American tropics, except that Microborus boops Blandford was introduced into tropical Africa. Microborus and Scolytodes are closely allied to one another; Pycnarthrum and Gymnochilus are remotely related to those and to one another. Pycnarthrum could just as easily be placed in the Hylesininae as in its present position. This tribe marks a transition from Scolytini to the more highly evolved tribes in this subfamily.

## Genus MICROBORUS Blandford

Microborus Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):175 (Type-species: Microborus hoops Blandford, monobasic)
Pseudocrypturgus Eggers, 1919, Ent. Blätt. 15:236
(Type-species: Pseudocrypturgus camerumus Eggers $=$ Microborus boops Blandford, monobasic); Wood, 1961, Great Basin Nat. 21:101. Synonymy
Diagnosis.- This genus is distinguished from Pycnarthrum Eichhoff by the very large, approximate eyes, by the unsegmented, subglobular antennal club, by the more slender body form, and by the hairlike vestiture.

Description.- Length 1.1-1.5 mm, 2.7-2.9 times as long as wide; color dark reddish brown; vestiture hairlike, bristles or occasional scales on declivity.

Frons convex; eyes narrowly separated above and below, shallowly emarginate, very coarsely faceted. Antennal club subglobular, feebly flattened, unmarked by sutures; funicle 6 -segmented; scape short. Pronotum elongate, unarmed, acutely margined laterally by elevated line. Scutellum small, flush with elytral surface. Elytral striae conspicuous; declivity rather steep, convex, armed on interstriae 2 in some species.

Sexually dimorphic characters usually limited to elytral declivity.

Distribution.-Guatemala to Surinam; one introduced species in tropical Africa; eight species are known, and four of them occur in Central America.

Bıology.- Species of this genus live in unusually moist habitats, where they infest logs and limbs previously infested by other beetles. The species are monogamous; they do
not construct their own entrance tunnel but utilize that of another species. The tunnels are somewhat nondirectional for both larvae and adults. Evidently several generations may be completed in one piece of bark; the converging brood tunnels become new egg galleries. The tumnels penetrate all parts of the phloem, but in thick-barked trees they are most abundant at the fracture point between inner and outer bark.

## Key to the Species of Microborus

1. Pronotal surface smooth, shining, with no suggestion of reticulation, punctures coarse, pronotum less than 1.26 times as long as wide; elytral vestiture more abundant, extending to base on both striae and interstriae, little if any longer on declivity

- Pronotum slightly to entirely reticulate, punctures fine to moderately coarse, pronotum more slender, at least 1.27 times as long as wide; elytral vestiture largely absent from disc, strial setae rarely present, interstrial setae conspicuously longer on declivity3

2(1). Elytral declivity without an acutely elevated carina from junction of interstriae 7 and 9 to sutural apex; frons smooth. shining; pronotum more slender, 1.26 times as long as wide; Puerto Rico; 1.3-1.6 mm ...................................... lautus Wood

- Elytral declivity with an acutely elevated carina from junction of interstriae 7 and 9 to sutural apex; frons uniformly, strongly reticulate; pronotum stouter, 1.1 times as long as wide; Morelia; Bursera; $1.0-1.1 \mathrm{~mm}$............. 1. mexicanus Wood

3(1). Punctures on at least discal interstriae 3 and 4 minute, almost obsolete, very widely spaced; vestiture absent except sparse and minute on declivity; tubercles on male declivital interstriae 2 small, not larger than in female4

- Punctures on discal interstriae closer, more regular; elytral vestiture more abundant, longer; one or more tubercles on male declivital interstriae 2 conspicuously wider than on female
4(3). Discal striae not impressed, punctures small; pronotal punctures fine, rather sparse; declivital interstrial granules minute, scarcely visible; Costa Rica; 1.3-1.5 2. limatus Wood
- Discal striae distinctly impressed, punctures rather coarse; pronotal punctures rather coarse, close; declivital interstrial granules larger, clearly visible; Veracruz to Tabasco; 1.3-1.4 mm 3. ambitus Wood

5(3). Eyes broadly separated above by twice width of an eye; tubercles on male declivital interstriae 2 only slightly enlarged; setae on all declivital interstriae uniseriate, none longer than distance between rows; crest of subapical declivital carina of almost uniform height, only feebly serrate; Venezuela; Clusia; $1.4-1.5 \mathrm{~mm}$ lectus Wood

- Eyes narrowly separated above by half width of an eye; one to four tubercles on male declivital interstriae 2 enlarged; setae (except on a few females) on at least declivital interstriae 2 abundant, confused, most much longer than distance between rows; crest of subapical declivital carina more strongly serrate

6(5). Discal striae more strongly impressed, as wide or wider than interstriae; setae on declivital interstriae as long as distance between rows, those on 3 usually uniseriate; crest of subapical declivital carina strongly serrate; Guatemala to Panama, etc.; Rheedia, lianas, etc.; $1.2-1.4 \mathrm{~mm}$ $\qquad$ 4. boops Blandford

- Declivital striae feebly impressed, narrower than interstriae; setae on declivital interstriae up to two or more times longer than distance between rows, those on 3 abundant and confused; crest of subapical declivital carina only moderately serrate; Venezuela to Surinam; Clusia; 1.3-1.4 mm $\qquad$ imitans Eggers

## 1. Microborus mexicanus Wood

Microborus mexicamus Wood, 1981. Great Basin Nat. 41:12:3 (Holotype, male; Las Piedras, Moyotepec. Morelia, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from lautus Wood by the darker color, by the stouter body and pronotum, by the different declivity, and by other characters described below.

Male.-Length $1.0-1.1 \mathrm{~mm}, 2.3$ times as long as wide; color almost black.

Frons convex, reticulate; eyes separated above by 2.5 times width of an eve. Antenna typical of genus, with funicle stouter than normal.

Pronotum 1.1 times as long as wide; sides straight and parallel on basal half, rather broadly rounded in front; surface smooth, shining, punctures rather coarse, deep, spaced by less than diameter of a puncture. Short hairlike setae arise from punctures, each about as long as diameter of a puncture.

Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; outline and dise as in lautus except striae more distinctly impressed; declivity steeper than but similar to lautus except on declivity interstriae 7 and 9 more acutely carinate, acute carina continuing from their junction to apex; strial setae continue to base, only very slightly shorter than those of interstriae; interstrial setae extend to base, close, uniseriate on disc, each three-fourths as long as distance between rows, slightly longer on declivity, slightly confused on 2 and 3.

Female. - Similar to male except setae on declivital interstriae 2 and 3 less obviously confused.

Distribution.- Morelia.
MEXICO: Morelia: Las Piedras, Moyotepec, 17-VII$80,1060 \mathrm{~m}$, No. S-077, Bursera, T. H. Atkinson.

Notes.- The above treatment was based on the type series of five specimens.

## 2. Microborus limatus Wood

Microborus limatus Wood, 1969. Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):13 (Holotype, male; Finca Gromaco on Río Coto Brus, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- This species may be distinguished by characters summarized in the above key.

Male.- Length 1.3-1.5 mm, 2.7 times as long as wide; body color dark brown, elytra medium brown.

Frons narrow and feebly convex between eyes, protruding very slightly just above antennal bases; surface smooth and polished, with a few scattered, minute punctures; almost glabrous. Eyes very large, almost touching below; anterior margin very broadly emarginate; very coarsely faceted. Antennal scape short, about twice as long as pedicel; funicle 6 -segmented; club subglobular, sutures obscurely marked by rows of setae.

Pronotum 1.25 times as long as wide; sides almost straight and parallel on basal threefourths, rather broadly rounded in front; anterior angles not narrowed; surface shining, weakly reticulate, punctures rather small, shallow, separated from one another by one to two diameters of a puncture. Glabrous.

Elytra 1.9 times as long as wide; sides almost straight and parallel on basal threefourths, narrowly (subangulately) rounded behind; striae 1 moderately, 2 weakly impressed, narrow, punctures small, separated by distances equal to their own diameters; interstriae distinctly wider than striae, smooth, brightly shining, each with a sparse row of minute punctures. Declivity rather steep, not precipitous; striae and interstriae about as on disc, except interstrial punctures very finely granulate; interstriae 7 and 9 acutely elevated from declivital base to point of fusion, acute elevation continuing to apex. Vestiture short, sparse, almost entirely
restricted to declivity; each hairlike seta about equal to half width of an interstriae, and separated from one another by about one and one-half to two times length of a setae.

Female.-Similar to male except more finely sculptured; declivital granules scarcely visible.

Distribution.- Costa Rica.
costa rica: Finca Gromaco on Río Coto Brus, Puntarenas, 14-V11-63, $50(0) \mathrm{m}$. No. 87, S. L. Wood.

Biology.- This species was taken in series with a species of Gnatholeptus from thick bark of recently cut limbs 20 cm in diameter.

Notes.- The above treatment was based on the type series of 13 specimens.

## 13. Microborus ambitus Wood

Microborus ambitus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. I0(2);13 (Holotype, female; 25 km E Coatzocoalcos, Veracruz, Mexico: Wood Coll.)
Diagnosis.- This species may be distinguished by characters summarized in the above key.

Female.- Length 1.3-1.4 mm, 2.9 times as long as wide; color of head and pronotum very dark brown, posterior areas and legs reddish brown.

Head, pronotum, and elytral disc as in limatus Wood except as noted in the key. Pronotal punctures slightly deeper. Elytral declivity convex, steep; striae slightly impressed, punctures coarse, deep; interstriae slightly narrower than striae, very slightly convex, each bearing a uniseriate row of fine granules; interstriae 7 very acutely, strongly elevated, joining 9 and continuing but declining in height slightly along costal margin to sutural apex, 9 narrowly, not strongly elevated from level of hind coxae to junction with 7. Vestiture confined to declivity, consisting of interstrial rows of fine, short, almost hairlike bristles.

Male.- Both sexes probably represented in series at hand but sexual differences not apparent.

Distribution.- Veracruz and Tabasco.
MExICO: Veracruz: 25 km E Coatzocoalcos, 26-VI$67,30 \mathrm{~m}$, No. 110 . Tabasco: 22 km W Cárdenas, 26-V1$67,30 \mathrm{~m}$, No. 106, all by S. L. Wood.

Biology.- Both series were taken from the same host species in cut limbs and boles
$10-20 \mathrm{~cm}$ in diameter. It was taken in series with a species of Pityophthorus.

Notes.- The above treatment was based on the type series of six specimens.

## 4. Microborus boops Blandford

Microborus boops Blandford, 1897, Biol. Centr. Amer., Coleopt. $4(6): 175$ (Holotype, female; Tamahú, Alta Verapaz, Guatemala; British Mus. Nat. Hist.)
Pscudocrypturgus camerunus Eggers, 1919, Ent. Blätt. 15:236 (Sex ?: Kamerun; Schreiner Coll., destroyed with Hamburg Mus.). New synonymy
Diagnosis.- This species may be distinguished by characters summarized in the above key.
Female.- Length $1.2-1.4 \mathrm{~mm}, 2.7$ times as long as wide; color dark reddish brown.
Head, pronotum, and elytral disc as in limatus except as noted in key. Elytral declivity steep, convex; striae slightly impressed, punctures deep, rather coarse; interstriae as wide as striae, weakly convex, shining, most minute punctures finely granulate; interstriae 7 and 9 acutely elevated, converging posteriorly and continuing to apex, about as high as thick. Vestiture consisting of moderately abundant long hair on declivity, each seta about equal in length to twice width of an interstriae.

Male.- Similar to female except striae more strongly impressed on dise, interstriae on disc more coarsely sculptured; declivital interstriae more convex, 2 usually slightly elevated and frequently armed by one to six small teeth, granules on other interstriae slightly larger than in female; lateral costa on declivity slightly higher, often scalloped or subserrate; vestiture coarser. Declivity, particularly interstriae 2 , variable within and be tween series, left and right sides of same specimen may differ strikingly.

Distribution.-Guatemala to Panama, Jamaica, and Africa.

GUATEMALA: Tamahú, Alta Verapaz, G. C. Champion. HONDURAS: La Ceiba, 29-V-49, and Olanchito, 19-V-49, both at light, E. C. Becker. COSTA RICA: Turrialba, Cartago, 9-III-64, 700 m , No. 469 , woody vine; Río Damitas, Dota Mts., San José, 18-II-64, 250 m , No. 434, Rheedia edulis, both by me. PANAMA: Barro Colorado Island, Canal Zone, I6-IV-67, H. Hespenheide.

Hosts.- Rheedia edulis and a woody vine (liana).

Biology.- As described for the genus.
Notes.- More than 60 specimens of this species were examined, including the female holotype from Guatemala, 7 specimens from Africa (including a male cotype of Pseudocrypturgus camerunus), 2 from Jamaica, 2 from Honduras, and 56 from Costa Rica. The females are relatively constant in anatomical features, but the males present a surprising degree of variation.

In two males from Río Damitas, declivital interstriae 2 is armed by two pairs of pointed denticles; the declivital setae are almost as coarse and only slightly longer than on males from Africa and Honduras. Of the 12 males from Turrialba, Cartago Prov., the declivital interstriae 2 is unarmed by denticles on 7 specimens, but on the 5 remaining specimens there are from one to five denticles on each side (the total number on both sides varying from one to seven). In addition, declivital interstriae 1 to 7 bear rounded granules in all specimens; these granules vary from minute in some specimens to moderately large, rounded nodules in others. The transition is gradual within the series and is not related to the presence or absence of teeth on interstriae 2. The vestiture is rather coarse and is about equal in length to twice the distance between rows of bristles. Some specimens clearly are the same as the African and Honduras specimens, others are like the Rio Damitas specimens. Because the entire Turrialba series came from the same small piece of host material, it is clear that only one species is represented. In view of this, it appears that camerunus (Eggers), from Africa and Honduras, represents only one variation of a widely distributed, variable species.

## Genus PYCNARTHRUM Eichhoff

Pycnarthrum Eichhoff, 1878, preprint of Mém. Soc. Roy. Sci. Liége (2)8:41, 104 (Type-species: Pycnarth-
rum gracile Eichhoff $=P$. hispidum Ferrari, subseguent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:128)
Nemohius Chapuis, 1869 (nec. Serville, 1839), Synopsis des Scolytides, p. 41 (Type-species: Nemohius lambottei Chapuis $=P$. hispidum Ferrari, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48: I28). Preoccupied
Monebius Hopkins, 1914, Proc. U.S. Nat. Mus. 48:125
(Replacement name)
Nomebius Navas, 1915. Bol. Soc. Aragonesa Cienc. Nat. 14:34 (Replacement name)
Diagnosis.- This genus is distinguished by the large, very coarsely faceted eyes, by the 6 -segmented funicle, by the asymmetrical, flattened antennal club, with two or three suboblique sutures, by the dense, short vestiture, and by other characters summarized in the above key.

Description.- Length $1.3-2.1 \mathrm{~mm}, 2.2$ times as long as wide; color pale yellow to black.

Frons dimorphic, flattened to convex in female, flattened to concave in male; eye elongate, approximate below, separated above by a distance as great or greater than width of eye, rather coarsely faceted. Antennal scape long; funicle 6 -segmented; club flattened, asymmetrical, sutures 1 and 2 clearly marked by setae, 1 partly septate. Pronotum quadrate, unarmed, punctured; lateral margins acutely elevated. Scutellum small, oval; elytra striate, declivity rather steep, flattened or convex; unarmed; vestiture short, rather abundant. Tibiae characteristic of tribe.

Distribution.-S Florida and Mexico to Brazil. More than a dozen names have been proposed in the genus, but there is a great deal of synonymy; seven species occur in North and Central America.

Biology. - These monogamous species construct biramous parental galleries in the cambium region of the host tree, where they deposit eggs individually in specially prepared niches as in other bark beetle groups. The larval mines wander at random. Populations frequently are so dense that gallery patterns are completely obliterated.

Key to the Species of Pycnarthrum

1. Interstriae completely devoid of all traces of median rows of bristles; bristles or long hair also absent on head, thorax, or other parts of body; interstrial

punctures confused, uniformly minute; male frons flattened; Honduras; 1.6
mm

1. inornatum Wood

- Interstriae each with a median row of closely set, longer, stouter setae in addition to ground cover; longer setae also present on anterior or lateral areas of thorax and other areas; a median row of interstrial punctures usually evident in addition to fine, confused punctures

2(1). Interstrial ground cover scalelike or subplumose on both disc and declivity; erect bristles on anterior half of disc stout, usually less than four times as long as wide, each shorter in length than width of an interstriae

- Interstrial ground cover on anterior half of disc very fine, hairlike; erect bristles on anterior half of disc slender, at least six times as long as wide, each equal in length to width of an interstriae .5

3(2). Male frons rather deeply concave from upper level of eyes to epistoma, female frons convex, very finely granulate; mature color yellow; elytral declivity more narrowly convex, strial punctures less deeply impressed, somewhat confluent toward apex; Chiapas to Venezuela; Ficus; 1.6-1.7 mm
2. reticulatum Schedl

- Male frons flattened; female frons convex, reticulate, clearly punctured; color darker

4(2). Striae not impressed, punctures rather small, shallow, distinct; setae in elytral ground vestiture more slender, scarcely if at all subplumose; pronotum more finely punctured; color black; Honduras; 1.3-1.4 mm .................. 3. furnerium Wood

- Striae often weakly impressed, punctures rather coarse, deep; setae in elytral ground vestiture stouter, more nearly subplumose; pronotal punctures coarser; color dark brown, elytra often lighter; S Texas and Florida to Panama and British Guiana; Ficus; 1.5-2.1 mm

4. hispidum (Ferrari)

5(2). Male frons flattened; pronotal punctures moderately coarse, not as close; strial punctures on disc deeper, those toward base wider than long; elytral declivity steeper, strial punctures smaller, not as deep, vestiture shorter, more abundant; color very dark brown; Honduras; 1.3-1.6 mm
5. perditum Wood

- Male frons either flattened or concave; pronotal punctures rather dense, fine; strial punctures not as deep or as crowded, circular; elytral declivity not as steep, strial punctures larger, deeper, vestiture less abundant, longer; color yellowish to light brown

6(5). Male frons flattened; declivity more evenly convex, including central area; punctures on male striae 1 smaller, as on 2 , granules on male interstriae 2 min ute; elytral setae averaging stouter, slightly shorter; Costa Rica; Cedrela; $1.5-1.9 \mathrm{~mm}$
6. lucidum Wood

- Male frons moderately concave; declivity distinctly impressed in central area; punctures on male striae 1 much larger than those on 2; granules on male discal interstriae 2 larger; elytral setae more slender, slightly longer; Costa Rica to Colombia and Venezuela; Brosimum; 1.9-2.2 mm

7. brosimi Wood

## 1. Pycnarthrum inornatum Wood

Pyonarthrum inomatum Wood, 1971. Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):11 (Holotype, female; Olanchito, Honduras; Wood Coll.
Diagnosis.- This species, at least superficially, is very similar to hispidum (Ferrari) except that all long setae or bristles are absent from the entire body: the vestiture consists only of the very short ground cover of scales.

Female.- Length 1.6 mm , about 2.2 times as long as wide (elytra of type spread slightly); color very dark brown, elytra lighter.

Frons weakly convex except indistinctly concave on central third: eyes separated above by distance greater than width of an eye; surface reticulate, punctures moderately coarse, rather close, sharply, not deeply impressed; vestiture of minute hair and scales, each not longer than twice diameter of a puncture. Antennal club and flagellum missing on type.

Pronotum about equal in length and width; widest at middle, sides weakly arcuate. broadly rounded in front; surface shining, subreticulate on anterior surface, with minute points moderately abundant, punctures moderately coarse, deep, close, interspaces not wider than distance equal to diameter of a puncture. Vestiture inconspicuous, consisting of short, slender hair and on anterior half some equally short, stout setae intermixed.

Elytra about 1.4 times as long as wide; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae 1 moderately, others not impressed, punctures coarse, deep, rather close; interstriae as wide as striae, subshining, very obscurely subreticulate, punctures small, moderately abundant, confused. Declivity steep, broadly convex; interstriae 2 somewhat impressed, narrower than others. Vestiture consisting of minute strial hair on disc only, and short, confused, subplumose, narrow scales equally abundant on disc and declivity; rows of erect bristles found in other species of this genus entirely absent.

Distribution.- Honduras.
HONDURAS: Olanchito, Yero, 7-X-49, at light. E. C. Becker.

Notes.- The above treatment was based on the holotype.

## 2. Pyncnarthrum reticulatum Schedl

Pycnurthrum reficulutum Schedl, 1940, An. Esc. Nac. Cienc. Biol. (Mexico) 1:355 (Lectotype, female: Tonalá, Chiapas, Mexico; Schedl Coll., designated by Wood, 197t, Great Basin Nat. 3425 \%
Pycharthrum fici Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):11 (Holotype, male: 5 km W El Pino, Merida, Venezuela: Wood Coll.); Wood. 1974. Great Basin Nat. 34: 257. Synonymy

Diagnosis. - This species superficially resembles hispidum (Ferrari), but it may be distinguished by the deeply concave male frons, by the pale yellow, mature body color, by the more narrowly convex elytral declivity, and by the shorter elytral vestiture.

Female.- Length $1.6-1.7 \mathrm{~mm}, 2.2$ times as long as wide; color pale vellow.

Frons moderately convex to near epistoma; surface reticulate to very finely subrugulose, punctures minute, indistinct; eves rather narrowly separated above, separated by distance equal to 1.5 times width of an eye; vestiture of rather fine, short, moderately abundant setae. Antennal club 1.6 times as long as wide, sutures 1 and 2 distinct, 3 obscurely indicated.

Pronotum proportions and outline as in hispidum; surface reticulate on anterior third, obscurely subreticulate behind, punctures uniformly rather small, shallow, close. Vestiture very short, of fine and stout setae intermixed.

Elytra 1.4 times as long as wide; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae weakly impressed, punctures very shallow, obscurely impressed, of moderate size; interstriae about one and one-half times as wide as striae, surface not regular, evidently very minutely rugose, punctures minute, many very minutely elevated, particularly along median row. Declivity rather steep, convex; striae and interstriae slightly narrower, striae more distinctly impressed, punctures less distinct. Vestiture consisting of short, stout, moderately abundant ground cover mostly in indefinite marginal rows on each interstriae, not subplumose, and interstrial rows of erect, stout bristles, each bristle about one and onethird times as long as ground setae, very slightly shorter in length than width of an interstriae, at least six times as long as wide.

Male. - Similar to female except frons rather deeply concave from upper level of eyes to epistoma; frontal surface perhaps a little more granulate.

Distribution.- Chiapas to Venezuela.
MEXICO: Chiapas: Tonalá, 30-V11-32, Dampf. GUATEMALA: Cuyotenango, Suchitepiquez, 10-IV-65, J. M. Campbell. HONDURAS: La Ceiba, Atlántida, $15-$ V, 26-VIII-49, at light, E. C. Becker; Olanchito, Yoro, 21-VI, 8-1X-49, at light, E. C. Becker. OTHER COUNTRIES: Venezuela, Jamaica.

Host. - Ficus spp.
Biology.- In Venezuela this species attacked limbs and bole of the host. Parental galleries were biramous and transverse; larval mines so completely riddled the inner bark that a pattern could not be ascertained.

Notes. - The above treatment was based on the lectotype of reticulatum, on the type series of fici, and on five specimens from Honduras.

## 3. Pycnarthrum funerium Wood

Pycnarthrum funerium Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):11 (Holotype, female; La Ceiba, Atlántida, Honduras: Wood Coll.)
Diagnosis.- This species is distinguished from hispidum (Ferrari) by the very small size, by the black color, by the small, shallowly impressed strial punctures, and by the more slender, less plumose setae in the elytral ground vestiture.

Female.- Length 1.3-1.4 mm, 2.2 times as long as wide; color black.

Frons rather strongly, evenly convex to epistoma; surface reticulate, becoming subrugulose below, punctures fine, shallow, obscure; eyes separated by distance greater than width of an eye; vestiture of rather sparse, stout, erect, moderately long, white bristles. Antennal club 2.0 times as long as wide; two sutures indicated.

Pronotum 0.93 times as long as wide; widest at or slightly in front of middle, sides weakly arcuate, very broadly rounded in front; surface strongly reticulate on anterior third, obscurely reticulate behind, subshining, punctures small, close, moderately deep. Vestiture of fine hair and stout bristles intermixed over entire surface, moderately long.

Elytra about 1.4 times as long as wide; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind;
striae not impressed, punctures rather small, distinct, very shallow; interstriae almost twice as wide as striae, evidently obscurely subreticulate, median row of punctures uniseriate, very small but almost twice as large as confused supplementary punctures. Declivity rather steep, rather narrowly convex, not at all impressed; essentially as on disc, except strial punctures very slightly deeper. Vestiture consisting of short ground cover of rather fine (anteriorly) to stout (posteriorly), semirecumbent, hairlike bristles, a few exhibit indications of being subplumose; and longer, erect, uniseriate rows of stout, almost scalelike setae, each slightly less than twice as long as ground vestiture and about four to six times as long as wide; not longer on declivity.

Distribution.- Honduras.
HONDURAS: La Ceiba, 27,29-V, 10-VI-49, at light, E. C. Becker.

Notes.- The above treatment was based on the four females in the type series.

## 4. Pycnarthrum hispidum (Ferrari)

Fig. 140

Hypoborus (?) hispidus Ferrari, 1867, Die Forst- und Baumzuchtschädlichen Borkenkäfer, p. 19 (Sex?; Cuba; lost, missing from its pin at Vienna Mus.)
Nemohius lambottei Chapuis, 1869, Synopsis des Scolytides, p. 42 (Lectotype, female; Teapa, Mexico: Brussels Mus., designated by Wood, 1973, Great Basin Nat. 3.3:183). Synonymy
Pycnarthrum gracile Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:41, 104 (Lectotype, male; Cuba; U.S. Nat. Mus., designated by Wood, 1973, Great Ba$\sin$ Nat. 33:183). Synonymy
Pycnarthrum quadraticolle Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2):8:41, 106 (Lectotype, male; Mexico; U.S. Nat. Mus., designated by Wood, 1973, Great Basin Nat. 33:183). Synonymy
Pycnarthrum transversum Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):177 (Lectotype, female; Mirandilla, Guatemala; British Mus. Nat. Hist., designated by Wood, 1973, Great Basin Nat. 33:183). Synonymy
Pycnarthrum reimoseri Schedl, 1934, Ent. Blätt. 30:208 (Female syntypes; Jimenez on Osa Peninsula, and Volcán Irazu, Costa Rica; Viemma Mus. and Schedl Coll.); Wood, 1973, Great Basin Nat. 33:183. Synonymy
Diagnosis.- This very abundant species is taken or seen by almost anyone who collects insects at light within its range for any length of time. The above key summarizes the distinguishing characters.

Female.- Length 1.5-2.1 mm, 2.2 times as long as wide; color very dark brown, elytra, legs, and antennae somewhat lighter, vestiture light yellowish white.

Frons moderately convex to epistoma; surface reticulate, punctures moderately coarse, distinctly impressed, rather close; eyes widely separated; vestiture of fine and stout setae of moderate length intermixed. Antennal club 1.5 times as long as wide, two sutures indicated.

Pronotum 0.94 times as long as wide; widest at or in front of middle, sides weakly arcuate, broadly rounded in front; surface reticulate on anterior third, subshining, with rather numerous, very minute points behind, punctures irregular in size, moderately coarse, close, deep. Vestiture of rather short, fine, and stout setae intermixed.

Elytra 1.3 times as long as wide; sides almost straight and parallel on basal two-thirds, broadly rounded behind; striae usually weakly impressed, punctures coarse, deep, rather close; interstriae as wide as striae, almost smooth, punctures fine, confused, an indefinite median row (bearing erect bristles) indistinctly larger. Declivity rather steep, broadly flattened; striae more distinctly impressed, punctures slightly smaller; interstriae weakly convex, l slightly elevated, median rows of punctures more conspicuous. Vestiture of moderately abundant, short,
subplumose scales in ground cover, and median rows of erect, stout bristles, each bristle slightly less than twice as long as ground setae, at least six times as long as wide, about equal in length to width of an interstriae.

Male.-Similar to female except frons flat from upper level of eyes to epistoma, feebly concave near center; frontal vestiture distinctly longer.

Distribution.-S Texas and Florida to Panama and British Guiana.

USA: S Florida, S Texas. MEXICO: Chiapas, Colima, Jalisco, Michoacán, Oaxaca, Puebla, Tabasco, Tamaulipas. Veracruz, Yucatán. OTHER COUNTRIES: Costa Rica, Guatemala, Honduras, Panama, El Salvador, Cuba, Guadeloupe, Jamaica, Puerto Rico, Virgin Islands, British Guiana.

Host.- Ficus spp.
Biology.- This abundant species occurs in fig trees from sea level to an elevation of about 1300 m ; it is rather uncommon at higher elevations. It infests almost any area of bark on cut or injured limbs or bole larger than 5 cm in diameter. Parental galleries are biramous, transverse, and almost entirely in the bark. Larval mines wander aimlessly and usually completely obliterate parental mines. Development evidently is very rapid, thus permitting more than one generation to attack the same felled tree.

Notes.- The holotype of hispidum is missing from its pin and is presumed lost. Eichhoff (1878:105) appears to have examined

Fig. 140. Pycnarthrum hispidum female: 1, dorsal aspect; 2, antenna; 3, metatibia.

Ferrari's specimen and considered it to be synonymous with his gracile. If Eichhoff's generic placement of hispidum is correct, then the synonymy is acceptable because it is the only representative of the genus known from Cuba.

The above treatment was based on the lectotypes of lambottei, gracile, quadraticole, and transversum, on at least 2 syntypes of reimoseri, and on more than 1000 other specimens.

This very common species is attracted to light, where it is often collected in large numbers.

## 5. Pycnarthrum perditum Wood

Pycnarthrum lucidum Wood, 1971, Brigham Young Univ. Sci. Bull. Biol. Ser. I5(3):12 (Holotype, male; Finca Gromaco on Río Coto Brus, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- This species and lucidum Wood have the small setae on the basal half of the elytra much more slender, and the erect bristles longer than in other representatives of the genus. From lucidum this species is distinguished by the larger, more widely spaced pronotal punctures, by the more abrupt slope of the elytral declivity, and by the less strongly impressed male frons.

Female. - Length $1.3-1.6 \mathrm{~mm}, 2.3$ times as long as wide; color very dark brown, elytra, legs, and antennae lighter, vestiture pale yellowish white.

Frons convex from upper level of eyes to epistoma; surface reticulate, rather finely, shallowly punctured, a conspicuous median fovea at center; eyes separated above by 1.4 times width of an eye. Antennal club 2.0 times as long as wide; sutures 1 and 2 indicated.

Pronotum proportions, outline, and sculpture as in hispidum except punctures uniformly rather large, deep, not as close; vestiture of fine hair except intermixed with stouter setae on margins and on anterior fifth.

Elytra 1.5 times as long as wide; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae 1 feebly, others not impressed, punctures moderately large, rather deep; interstriae as wide as striae, punctures of two sizes, a median row of small punctures and less abundant
very minute punctures on margins of interstriae. Declivity rather steep, convex; striae distinctly impressed, narrower than on disc; interstriae weakly convex. Vestiture of fine strial hair and equally fine, short, recumbent, sparse interstrial hair, and interstrial rows of longer, erect, slender bristles, each bristle one and one-half times as long as ground vestiture, equal in length to width of an interstriae, more than eight times as long as wide.

Male.-Similar to female except frons more weakly convex, flattened on median area on lower half; frontal fovea present; interstrial bristles slightly stouter.

Distribution.- Honduras.
honduras: La Ceiba, Atlántida, 26-vill-49, at light, E. C. Becker.

Notes. - The type series of two specimens was used to prepare the above treatment.

## 6. Pycnarthrum lucidum Wood

Pycnarthrum lucidum Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3): 12 (Holotype, male; Finca Gromaco on Río Coto Brus, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from perditum Wood by the concave male frons, by the closer, finer, pronotal punctures, by the more gradual elytral declivity, by the larger, deeper strial punctures, and by the less abundant, finer pronotal and elytral vestiture.

Female.- Length $1.5-1.9 \mathrm{~mm}, 2.3$ times as long as wide; color brown, elytra somewhat lighter, vestiture pale.

Frons convex from upper level of eyes to epistoma, a feeble, transverse impression near center; surface shining, obscurely reticulate; punctures rather fine, deep, rather close; eyes separated by distance equal to width of an eye. Antennal club 1.6 times as long as wide, sutures 1 and 2 distinct, 3 obscurely indicated.

Pronotum proportions and outline as in perditum; surface brightly shining except obscurely reticulate on anterior third; minute impressed points present, punctures rather small, deep, close. Vestiture mostly abraded, very fine, a few coarse setae in anterolateral areas.

Elytra 1.4 times as long as wide; sides straight and parallel on basal two-thirds,
rather narrowly rounded behind; striae weakly impressed, punctures coarse, close, moderately deep; interstriae slightly wider than striae, almost smooth, shining, punctures very fine, in three obscure ranks, median row very slightly larger. Declivity rather steep, convex, striae narrowly impressed, narrower than on disc; interstriae twice as wide as striae, rather weakly convex. Vestiture consisting of fine, short, strial hair and interstrial short ground cover of very fine hair on dise becoming scalelike on declivity, and interstrial rows of erect bristles, each bristle almost twice as long as ground cover, equal in length to width of an interstriae, about six to eight times as long as wide.

Male.- Similar to female except frons moderately concave from upper level of eyes to epistoma, a shining, transverse callus on median half of epistoma, an additional pair of calluses in lateral areas of concavity just above level of antennal insertion.

Distribution.- Costa Rica.
COSTA RICA: Playón, San José, 9-Vili-63, 20 m , No. 117, Cedro amarga, S. L. Wood; Finca Gromaco on Río Coto Brus, 14 -VII-63, No. 60, S. L. Wood.

## Host.- Cedrela mexicana.

Biology.- Large limbs and branches of cut or broken trees were attacked. The biramous, transverse, parental galleries were almost entirely in the phloem tissues. Larval mines were not oriented in any particular direction, but wandered.

Notes.- The above treatment was based on the type series of 15 specimens.

## 7. Pycnarthrum brosimi Wood

Pycnarthrum brosmii Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):14 (Holotype, male; 9 km S Barrancas, Barinas, Venezuela; Wood Coll.). Lapsis calami
Diagnosis.- This species is distinguished from lucidum Wood by the much finer pronotal and elytral discal punctures, the more strongly impressed elytral declivity, and the flattened male frons.

Male.- Length $1.9-2.1 \mathrm{~mm}, 2.3$ times as long as wide; color reddish brown.

Frons flattened from just below upper level of eyes to epistoma; surface shining, obscurely reticulate, punctures fine, moderately close; vestiture rather sparse, fine, erect, moderately long.

Pronotum about as in hispidum (Ferrari), except surface shining but subreticulate on anterior third; a few minute points, punctures fine, rather deep, moderately close; vestiture of fine, short bristles, a few longer setae on marginal areas.

Elytra 1.3 times as long as wide; outline as in hispidum; striae 1 slightly, others not impressed, punctures rather small, moderately close; interstriae twice as wide as striae, almost smooth, median row of punctures uniseriate, fine, becoming finely then rather conspicuously granulate in progressing from anterior to posterior areas, supplementary punctures on margins of each interstriae minute, irregularly spaced. Declivity rather steep, broadly flattened; strial punctures conspicuously larger and deeper than on disc; interstriae slightly wider than striae, 1 moderately elevated, 2 distinctly impressed, all interstriae with upper half uniseriately, rather finely granulate. Vestiture consisting of ground cover of fine, short, moderately abundant strial and interstrial hair, strial setae absent on declivity, interstrial ground cover on declivity of subplumose scales; and interstrial rows of erect bristles, each bristle slightly more than twice as long as ground cover, about equal in length to width of an interstriae, each at least eight times as long as wide.

Female.-Similar to male except frons moderately convex from upper level of eyes to epistoma.

Distribution.- Costa Rica to Venezuela.
COSTA RICA: Isla del Coco, IV-1980, Brosimum, G. Stevens. VENEZUELA: 9 km S Barrancas, Barinas; 8 km SW Bumbum and 10 km SE Miri, Barinas. COLOMBIA: 27 km NE Montoya, Santander; 24 km S Colonia, Valle de Cauca.

Host.- Brosimum sp.
Biology.- Specimens were taken from large limbs and boles of felled or broken trees.

Notes.- The above treatment was based on the type series of 54 specimens and 8 other specimens. A printing error in a reference work consulted for the name of the host for this species resulted in a lapsis calami that is corrected above.

## Genus GYMnOCHILUS Eichmoff

Gymnochilus Eichhoff, 1868, Berliner Ent. Zeitschr. 11:399 (Type-species: Gymnochilus zonatus Eichhoff, monobasic)

Problechilus Eichhoff, 1878, preprint of Mém. Soc. Roy. Sci. Liége (2) $8: 46,167$ (Replacement for Gymnochilus Eichhoff)
Meringopalpus Hagedorn, 1905, Bull. Mus. Paris 10:547 (Type-species: Meringopalpus fallax Hagedorn $=$ Gymnochilus zonatus Eichhoff, monobasic); Eggers, 19:32. Wiener Ent. Zeit. 49:226. Synonymy
Diagnosis. - This genus is allied to Scolytodes Ferrari, but it may be distinguished by the 7 -segmented antennal funicle, by the larger, broader antennal club, which usually has sutures indicated, by the different type of sexual dimorphism on the froms, by the abundant hairlike ground vestiture on the elytra, and (usually) by the abundant, coarse, pronotal asperities.

Description.- Length $1.5-2.3 \mathrm{~mm}$, 1.8-2.2 times as long as wide; color light brown or more commonly bicolored.

Frons in male broadly flattened to shallowly concave, in female convex; vestiture scanty; eye elongate, entire, finely faceted; antennal funicle 7 -segmented, club rather large, broad, sutures procurved if present. Pronotum sharply margined at sides and base, asperate, summit well behind middle. Scutellum present. Elytral bases obscurely
margined; weakly if at all striate; ground vestiture hairlike, abundant; finely sculptured; declivity rather steep, convex. Tibiae typical of tribe.

Distribution.- Neotropical realm; 17 species have been named from Mexico to Brazil and Bolivia; 4 of them occur in North and Central America.

Biology.- The species are monogamous phloem inhabiting bark beetles. They attack cut, broken or unthrifty limbs and boles, where they construct biramous parental galleries in the cambium region, engraving the wood moderately. The eggs are placed individually in niches along the margins of the tunnel. The larvae mine entirely in the phloem tissues, where they wander more or less without specific direction. Apparently they are highly host specific.

Notes.- Although originally presented in 1867 as Gymmochilus, Eichhoff (1878:167) changed this name to Problcchilus because of possible homonymy with Gymnochila Klug, 1834. The two names differ in gender, however; consequently, the name Gymnochilus Eichhoff is valid under the Code of Nomenclature.

## Key to the Species of Gymnochilus

1. Body stout, about 1.8 times as long as wide; antennal club with two conspicuous, strongly bisinuate, procurved sutures marked by rows of setae; male frons flattened to below upper level of eyes; female frons more strongly convex; strial punctures usually rather coarse, clearly impressed (variable) elytral bristles very coarse, blunt; very common; Durango to Panama; Ficus 1.5-2.3 mm
2. reitteri Eichhoff

- Body more slender, 2.0 times as long as wide; antennal club with sutures obscure or absent, not marked by rows of setae; male frons distinctly impressed to well above eves, female frons weakly convex; erect interstrial bristles slender, usually pointed
2(1). Body more slender, 2.2 times as long as wide; male frons moderately concave to upper level of eves; strial punctures minute, interstriae five or more times as wide as interstriae; Mexico to Puebla; Alnus; $2.0-2.2 \mathrm{~mm}$

2. alni Wood

- Body stouter, 2.0 times as long as wide; male frons subconcave to well above upper level of eyes; strial punctures larger, interstriae about two to three times as wide as striae 3
3(2). Smaller; asperate area of pronotum rather strongly reticulate on surface between asperities, punctures usually not evident; asperate area of pronotum occupying anterior two-thirds ( 67 percent), distance from base to asperities greater in lateral areas than behind summit; erect elytral setae moderately stout; "Mexico" to Costa Rica; Ficus; 1.5-1.9 mm
- Larger; surface between pronotal asperities smooth, shining, with very fine, deep punctures; asperate area of pronotum occupying anterior three-fourths ( 75 percent), distance from base to asperities equal in lateral and median areas; Guatemala and Venezuela; Ficus; 2.0-2.8 mm

4. consocius (Blandford)

## 1. Gymnochilus reitteri Eichhoff

Gymnochilus reittcri Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:169 (Lectotype, male: Mexico; U.S. Nat. Mus., present designation)
Prohlechilus striatus Eggers, 1932, Wiener Ent. Zeit. 49:227 (Holotype, male; Canelas, probably Durango, Mexico; U.S. Nat. Mus., 60237); Wood, 1979. Great Basin Nat. 39:135. Synonymy

Problechilus bicolor Eggers, 1932. Wiener Ent. Zeit. 19:228 (Holotype, male; Nicaragua; LT.S. Nat. Mus., 60231): Wood, 1979, Great Basin Nat. 39:135. Synonymy
Diagnosis.- This abundant species is commonly attracted to light; it is extremely variable in size, proportions, and sculpture, but it may be distinguished from the other Central American species by the distinct, procurved sutures 1 and 2 on the antennal club, by the stouter body form, by the larger, deeper strial punctures, and by the frontal characters.

Male.-Length $1.8-2.3 \mathrm{~mm}, 1.8$ times as long as wide; color usually dark brown to black, with basal third of pronotum and occasionally areas of elytra abruptly lighter.

Frons irregularly flattened from just below upper level of eyes to epistoma, convex above; surface strongly reticulate, subrugulose, punctures fine, rather shallow, moderately close; epistomal lobe large, broad, impressed medially; vestiture fine, sparse. Antennal club rather large, 1.3 times as long as wide; sutures 1 and 2 strongly, bisinuately procurved, conspicuously marked by rows of setae.

Pronotum 0.82 times as long as wide; widest on basal third, sides moderately arcuate from base to rather narrowly rounded anterior margin; lateral and basal margins marked by a fine, raised line; summit onethird length from base, anterior area and anterior margin rather coarsely, closely asperate; transition from asperate to granulate areas gradual, on a recurved transverse line; posterior area rather finely, closely granulate. Vestiture of fine, abundant, recumbent hair, a few coarse bristles in lateral and anterior areas.

Elytra 1.05 times as long as wide; sides almost straight and parallel on basal half, broadly rounded behind; striae weakly, distinctly impressed, punctures moderately large, rather shallow; interstriae about one and one-half times as wide as striae, very weakly convex, densely, rather finely punctured; sutural striae and interstriae impressed near base and to a lesser extent on declivity. Declivity commencing at or slightly anterior to middle, moderately steep, broadly convex; striae more strongly impressed, punctures deeper, occasional specimens with 1 or 3 or both weakly elevated. Vestiture of short, recumbent, very abundant hair; and, on oddnumbered interstriae, erect, rather widely spaced, rather long interstrial bristles; bristles stout, blunt, easily abraded.

Female. - Similar to male except frons distinctly convex; sutural striae and interstriae not impressed.

## Distribution.- Durango to Panama.

MEAICO: Durango: Canelas, G. C. Champion. 1slas Tres Marías: Arrovo IIondo, María Madre, 17-V-25, H. II. Kiefer. Michoacán: Zirimicuaro, 2-X1-80, $1350 \mathrm{~m}, \mathrm{~T}$. H. Atkinson. GUATEMALA: Cerro Zunil, Quezaltenango, C. C. Champion; Volcán de Agua, Esquintla, 19-V-64, 1000 m , No. 606, Ficus, S. L. Wood. NlCARACUA: "Nicaragua." COSTA RICA: Escasu, San José, 2-X-63, 1300 m . No. 217. Ficus, S. L. Wood; Tapantí, Cartago, 24-X-63, 1300 m, No. 246, Ficus, S. L. Wood. PANANA: Barro Colorado Island, Canal Zone, XI-40, 4669. Zetek.

## Hosts.-Ficus spp.

Biology. - Unthrifty, cut, or damaged limbs and bole of fig were selected for attack. Parental galleries were biramous, largely but not always transverse. Egg niches were large and were placed alternately on sides of the tunnel. Parental galleries engraved the wood lightly; larval mines, which were more or less longitudinal, were entirely in the phloem.

Notes.- The above treatment was based on 4 Eichhoff syntypes of reitteri, on Eggers's specimen that was compared to Eichhoff's syntypes, on the holotypes of striatus and
bicolor, and on 44 other specimens. The 4 Eichhoff syntypes in the U.S. National Museum are all mounted on one card on one pin. These specimens bear labels with Eichhoff's No. "61," "Mex," and "Problechilus reitteri Eichh., Type." Of the 2 males, one is marked by the word type and is here designated as the lectotype of reitteri.

## 2. Gymnochilus alni Wood

Gymnochilus alni Wood. 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3): I 4 (Holotype, male; 10 km NE Teziutlan, Puebla, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from reitteri Eichhoff by the concave male frons, by the elongate body, by the absence or near absence of sutures on the antennal club, and by the obsolescent strial punctures on the disc.

Male.- Length $2.0-2.2 \mathrm{~mm}, 2.2$ times as long as wide; color light brown to bicolored.

Frons rather shallowly, broadly concave from well above eyes to epistoma; surface strongly reticulate, a transverse, arcuate callus at and slightly above level of antennal insertion, punctures fine, shallow, moderately abundant; vestiture fine, very short, sparse. Antennal club 1.3 times as long as wide, sutures not clearly evident except basal portion slightly sclerotized to point where suture 1 normally located.

Pronotum 0.86 times as long as wide; outline, sculpture, and vestiture as in reitteri except posterior area finely, densely punctured.

Elytra 1.3 times as long as wide; sides almost straight and parallel on more than basal half, narrowly rounded behind; striae 1 distinctly, others feebly or not at all impressed, punctures small, scarcely distinguishable from those of interstriae; interstriae three to four times as wide as striae, obscurely subreticulate, rather finely, densely punctured. Declivity commencing at middle, moderately steep, convex; strial punctures small, distinct; interstriae l weakly elevated. Vestiture of short, recumbent, very abundant, fine hair; and sparse interstrial rows of erect bristles, those on even numbered interstriae only slightly longer than ground vestiture, on disc only, those on odd interstriae slender, equal in length to width of an interstriae on both dise and declivity.

Female.- Similar to male except frons weakly convex, callus present; short interstrial bristles on even-numbered interstriae slightly longer, extending to declivity.

Distribution. - Mexico to Puebla.
MEXICO: Mexico: Amecameca, 26-1X-1980, 2700 m , Alnus, T. H. Atkinson. Puebla: 10 km ( 6 miles) NE Teziutlán, 2-Vll-67, 1600 m, No. 141, Alhus, S. L. Wood.

Biology.- Specimens were recovered from stacked cordwood cut from the bole of a tree 40 cm in diameter. The galleries were largely obliterated, but were similar to those of reitteri.

Notes. - The above treatment was based on the type series of 26 specimens.

## 3. Gymnochilus minor (Blandford) <br> Fig. 141

Prohlechilus minor Blandford, 1897, Biol. Centr. Amer., Coleopt. $4(6): 172$ (Lectotype, male; Guatemala City, Guatemala; British Mus. Nat. Hist., present designation)

Fig. 141. Gymnochilus minor. antenna.

Problechilus tarius Schedl, 1951, Dusenia 2:86 (Holotype, female; Mexico; Sched Coll.); Wood, 1974, Great Basin Nat. 34:281. Synonymy
Diagnosis.- This species is distinguished from the closely allied alni Wood by the smaller size, by the less strongly impressed male frons, and by other characters mentioned in the above key. It is more likely to be confused with reitteri Eichhoff, from which it is distinguished by the smaller size, by the more slender body form, and by the more elongate antennal club with sutures almost obsolete and much more broadly, evenly procurved.

Male.-Length $1.5-1.9 \mathrm{~mm}, 2.0$ times as long as wide; color as in reitteri.

Frons planoconcavely, irregularly impressed from epistoma to well above eyes, lateral margins slightly, acutely elevated; surface sculpture as in reitteri. Antennal club 1.5 times as long as wide, smaller, flatter, more slender than in reitteri, with sutures almost obsolete, more evenly procurved, not marked by rows of setae.

Pronotum as in reitteri except asperities less numerous and averaging slightly larger, ending posteriorly rather abruptly on an almost straight transverse line (gradual and obtuse in reitteri); surface of posterior areas closely, clearly punctured.

Elytra 1.2 times as long as wide; surface features variable, essentially as in reitteri except strial punctures usually more distinct and erect interstrial bristles much more slender.

Female.- Similar to male except frons distinctly convex on upper two-thirds, flattened below, lateral margins not elevated, rounded; short bristles on even-numbered interstriae often present (occasionally in male also).

Distribution.- "Mexico" to Costa Rica.
MEXICO: "Mexico." GUATEMALA: Guatemala City, G. C. Champion; San Geronimo, Baja Verapaz, G. C. Champion; Volcán de Agua, 19-V-64, 1000 m , No. 606, Ficus, S. L. Wood. HONDURAS: La Lima, Cortez, 5-V-64, 200 m , No. 583, Ficus, S. L. Wood. COSTA RICA: Escasú, San José, 2-X-63, 1300 m , No. 217, Ficus, S. L. Wood; Tapantí, Cartago, $24-\mathrm{X}-63,1300 \mathrm{~m}$, No. 246, Ficus, S. L. Wood; Finca Gromaco on Rio Coto Brus, Puntarenas, 14-VII-63, No. 85, Ficus, S. L. Wood.

Host. - Ficus spp.
Biology.-As in reitteri. The two species may occur in the same branches and have
similar galleries. Ecological specialization probably occurs, but was not noted.
Notes. - The above treatment was based on 8 syntypes and on 69 other specimens. I here designate the male syntype, from near Guatemala City, on the first pin in the Blandford series now in the British Museum (Natural History), as the lectotype of Problechilus minor Blandford. The card on this pin is shared by a female paralectotype of this species.

## 4. Gymmochilus consocius (Blandford)

Problechilus consocius Blandford, 1897, Biol. Centr. Amer., Coleopt. $4(6): 171$ (Holotype, male; Cerro Zunil, Guatemala; British Mus. Nat. Hist.)
Problcchilus trimaculatus Schedl, 1935, Arch. Instit. Biol. Veget. 2:91 (Holotype, female; Venezuela, probably Colonia Tovar; Schedl Coll.); Wood, 1974, Great Basin Nat. 34: 281. Synonymy
Diagnosis.- This species is distinguished from minor (Blandford) by the much larger average size, by the smooth. shining, punctured surface between asperities on the anterior slope of the pronotum, and by other characters mentioned in the above key.

Male.- Length 2.0-2.8 mm, 1.9-2.0 times as long as wide; color as in reitteri Eichhoff.

Frons as in minor.
Pronotum as in minor except asperate area occupying anterior three-fourths, its posterior margin forming a straight, transverse line, as close to basal margin in lateral areas as behind summit; surface between asperities almost smooth and shining, with moderately abundant, small, deep punctures; posterior areas with dense, very small punctures, evidently somewhat deeper and closer than in minor.

Elytra essentially as in minor, impression of striae and strial punctures probably averaging slightly deeper, punctures indistinctly larger; dense interstrial punctures averaging deeper than in minor, interstrial ground vestiture distinctly finer, erect bristles more slender and averaging slightly longer.

Female.- Similar to male except lower frons less strongly impressed, upper half convex; pronotum more strongly convex, asperities averaging slightly larger.

Distribution.- Guatemala and Venezuela.

GUATEMALA: Cerro Zunil, $4000 \mathrm{ft},(1300 \mathrm{~m})$, G. C. Champion. VENEZUELA: La Carbonera Expt. For., 50 km NW Merida, Merida, 16-1X-69, 2500 m , No. 20, Ficus, S. L. Wood, Merida, Merida, 12-1X-69, No. 8, 7 -X-69, No. 42, 1700 m , Ficus, S. L. Wood.

Host.- Ficus spp.
Biology.- Essentially as in reitteri.
Notes. - The above treatment was based on the holotypes of consocius and trimaculatus, and on 102 other specimens.

The male frons, in the Venezuelan material, in the area above the upper level of the eyes, is more broadly impressed, with the lateral margins more acutely rounded than in the type of consocius. The type has this area as in minor. The difference is slight and, at the present time, is not regarded as significant. Perhaps at a future date the difference may be used to characterize geographical races.

The male type of fallax Hagedorn (3.2 mm ) was examined; it was also compared by Eggers to the type of zonatus Eichhoff (3.3 mm ) and declared to be synonymous. Since all type material of zonatus apparently is lost, Eggers's synonymy is accepted as being correct. Gymmochilus zonatus is very similar to consocius and could easily be confused with it, but it may be distinguished by the larger size, the finely reticulate pronotal surface both in the asperate and nonasperate areas, the larger punctures on the basal fourth of the pronotum, and the much less strongly impressed male frons, which is 1.5 times as long as wide (1.6-1.8 times in consocius).

## Genus SCOLYTODES Ferrari

Scolytodes Ferrari, 1967, Die Forst- und Baumzuchtschädlichen Borkenkäfer, p. 77 (Typespecies: Scolytodes laecigatus Ferrari, monobasic) Hexacolus Eichhoff, 1868. Berliner Ent. Zeitschr. 11:399 (Type-species: Hexacolus glaber Eichhoff, monobasic); Wood, 1971, Great Basin Nat. 31:141. Synonymy
Ctenophorus Chapuis, 1869, Synopsis des Scolytides, p. 49 (Type-species: Ctenophorus laevigatus Chapuis = Hexacolus lecis Blackman, monobasic); Wood, 1977, Great Basin Nat. 37:207. Synonymy Prionosceles Blandford, 1897, Biol. Centr. Amer., Coleopt. $f(6): 177$ (Type-species: Prionosceles
atratus Blandford, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:128); Wood, 1971, Great Basin Nat. 31:141. Synonymy Epomadius Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):179 (Type-species: Epomadius culcitatus Blandford, monobasic); Wood, 1977, Great Basin Nat. 37:384. Synonymy
Erineophilus Hopkins, 1902, Proc. Ent. Soc. Washington 5:34 (Type-species: Erineophilus schwarai Hopkins, monobasic); Schedl, 1952, Dusenia 3:346. Synonymy. ${ }^{\text {. }}$
Hylocurosoma Eggers, 1940, Arb. Morph. Taxon. Ent. Berlin-Dahlem 7:138 (Type-species: Hylocurosoma striatum Eggers, monobasic); Schedl, 1952. Dusenia 3:346. Synonymy
Diagnosis.- This large and potentially important genus is closely related to Gymnochilus Eichhoff, from which it may be distinguished by the (usually) sparse vestiture, by the small antennal club that is usually devoid of sutures, by the pronotal summit that is either at or in front of the middle, and by the 6 -segmented antennal funicle.

Description.- Length 0.9-3.5 mm, 1.9-2.9 times as long as wide; color yellowish or reddish brown to black; vestiture hairlike.
Frons sexually dimorphic, males usually simply convex, not ornamented, female concave to convex or variously grooved, usually ornamented by conspicuous tufts or brushes of hair. Eye elongate-oval, entire; finely faceted. Antennal scape moderately long; funicle 6 -segmented; club small, sutures if marked either straight or feebly procurved. Scutellum rather small, surface even with that of elytra. Pronotum large, lateral margins acutely marked by a raised line, basal margin usually with a less conspicuous raised line; surface variable, smooth to asperate anteriorly, variously punctured. Elytral bases transversely straight or weakly sinuate, with a finely raised margin; disc lisually striate; declivity rather steep, convex, sculpture very conservative; vestiture usually sparse, hairlike. Tibiae as defined for tribe.

Distribution.- Florida and Mexico to Argentina; more than a hundred species have been named in this genus; about half of them occur north of Panama.

Biology. - These usually monogamous species ordinarily construct a simple cavetype egg chamber entirely in phloem tissues, where eggs are deposited in clusters at the margins or in large, irregular niches or pockets. In some species this chamber is elongate,
definitely oriented, and with distinct, oversized egg niches that may contain one to several eggs each. Larval mines may be individual and wander indiscriminately in the phloem, or communal. In at least two species the parent beetle bored into the pith while larval development proceeded through the first and second instars; then third instar larvae invaded the pith through the parent tunnel, where they passed the remaining stages of development. Many species are very aggressive and regularly kill living branches, where a life cycle can be completed in less
than 20 days. A very few species appear to be polygynous, form radiate parental galleries, and deposit their eggs in individual niches.

Notes.- Seven generic names have been proposed for species now included in this group. This is an indication of the unusual variation found in the genus. Intergradation between groups within the genus, however, makes a workable subdivision impossible. Although there is considerable overlap between them, three subgenera were tentatively retained as indicated in the following key.

## Key to the Species of Scolytodes

1. Pronotum punctured from base to anterior margin, a few minute asperities
sometimes intermixed with punctures on anterior fourth ..................................... 2

- Pronotum punctured only on basal half, finely to coarsely asperate on anterior area, with no punctures intermixed (see also couplet 8) (Hexacolus)
2(1). Anterior tibiae broad, with a very thin, semitransparent extension of lateral margin between lateral teeth 2 and 3 and often between 3 and 4 , etc.; stout species, $1.6-3.4 \mathrm{~mm}$; in fallen Cecropia leaf petioles (Prionosceles)3
- Anterior tibiae with outer margin rounded, lateral teeth free to their bases; stout to slender species, variable in size and habits (Scolytodes).6

3(2). Strial and interstrial punctures small, confused from base to apex; Costa Rica to Colombia and Venezuela; $2.4-3.4 \mathrm{~mm}$

- Striae weakly impressed, punctures in rows, distinctly larger than those of interstriae
4(3). Smaller; elytral declivity convex, steeper; female frons uniformly concave, male frons evenly convex above, becoming flattened below; pronotum strongly reticulate, dull; Oaxaca and Veracruz to Panama and Venezuela; $1.6-2.1 \mathrm{~mm}$.. 2. maurus (Blandford)
- Larger; elytral declivity flattened between third interstriae; female frons with large epistomal callus, male frons irregularly inflated on lowerhalf; pronotum subreticulate, subshining 5
5(4). Average size larger; anterior third of pronotum less strongly reticulate, shining; interstrial granules on declivity averaging distinctly smaller; Veracruz to Honduras; 2.4-3.3 mm

3. atratus atratus (Blandford)

- Average size smaller; anterior third of pronotum reticulate, subshining; interstrial granules averaging distinctly larger; Costa Rica to Panama; 2.0-3.0 mm .. 4. atratus panamensis (Wood)

6(2). Interstriae 10 elevated or narrowly convex at least to base of declivity; anterior tibiae devoid of a minute tooth on posterior face (except perditus, amoenus)7

- Interstriae 10 narrowly convex only on basal third, elevation not extending posterior to level of hind coxae; anterior tibiae armed on posterior face by a small tooth just behind tarsal insertion and between inner terminal mucro and lateral tooth 1 or 2 (see also couplet 11)

| 7(6). | Interstrial punctures numerous, confused (usually uniseriate in levis); female frons flattened, with lower part of lateral margins at most only slightly raised, with a large, central, shining, impunctate area; body stout, 1.9-2.0 (2.2 in amoenus and levis) times as long as wide; larger, $1.9-2.7 \mathrm{~mm}$ $\qquad$ 8 |
| :---: | :---: |
| - | Interstrial punctures uniseriate; female frons armed by a pair of longitudinal carinae (except pseudopiceus, venustus); rather slender species, 2.1-2.4 times as long as wide; smaller, $1.4-1.9 \mathrm{~mm}$ $\qquad$ |
| 8(7). | Anterior third of pronotum totally devoid of asperities .......................................... 9 |
|  | Anterior third of pronotum armed by numerous, fine asperities ............................ 10 |
| 9(8). | Pronotum smooth, shining, punctures coarse, deep; female frontal vestiture shorter, less abundant, extending little if at all above upper level of eyes, glabrous central area occupying less than central third of frons; Guatemala to Costa Rica; Plumeria; 1.9-2.7 mm $\qquad$ 5. plumeriae W |

- Pronotum reticulate, dull, punctures very fine, shallow; female frontal vestiture extending higher on vertex, much longer, more abundant, glabrous area occupying much more than central half; Costa Rica; Phoebea; $2.0-2.6 \mathrm{~mm}$ (see also 7. minutissimus Schedl, 1.2 mm and 8. levis Blackman)

6. phoebeae Wood

10(8). Pronotum longer than wide, anterior margin armed by a continuous costa; female frons rather elaborately sculptured and ornamented by a fringe of long hair; Jalisco to Tamaulipas; Ficus; 1.9-2.3 mm (see also 10. lepidus Wood, 11. genialis Wood)
9. amoenus Wood

Pronotum distinctly wider than long, anterior margin unarmed; female frons
simple, glabrous or with a small patch of fine hair on median half .......................... 11
11(10). Smaller, more slender body; elytra glabrous; strial and interstrial punctures fine, shallow; female frons flat, finely pubescent on narrow flattened area; Panama; Cecropia; $1.6-2.0 \mathrm{~mm}$
12. perditus Wood

- Larger, stouter body; elytra with fine, rather short strial and interstrial hair; strial and interstrial punctures rather coarse, deep; female frons impressed on median third of lower half, glabrous; Costa Rica; Cecropia branches; 1.9-2.2 mm

13. cecropicolens Wood

12(7). Female frons armed by a pair of longitudinal carinae; pronotum smooth, not
distinctly asperate anteriorly, punctures not obscured in either sex ....................... 13

- Female frons broadly flattened, with no indication of longitudinal carinae; anterior area of male pronotum usually finely asperate, intermixed punctures sometimes attaining anterior margin only in lateral areas17

13(12). Strial and interstrial punctures distinctly impressed throughout; female frons
armed by two widely spaced or diverging carinae .............................................. 14

- $\quad$ Strial punctures feebly impressed on basal half, obscure toward declivity; interstrial punctures obscurely indicated; male frons reticulate, dull, a few very obscure punctures; female frons armed by two closely placed, longitudinal carinae, separated by a distance about equal to thickness of one carina; elytra narrowly, but more broadly rounded behind (female of blandfordi not seen)15

14(13). Anterior third of pronotum finely asperate, disc coarsely, rather shallowly punctured; female frons on lower half with lateral thirds bearing a pair of oblique, diverging carinae, upper half bearing a strong, median carina, vestiture on lateral and upper margins long, rather sparse; Guatemala; 1.7 mm (see also 14. costabilis Wood)

- Anterior third of pronotum devoid of asperities, punctures very fine; female frons bearing a pair of parallel longitudinal carinae dividing frons into approximately equal thirds, vestiture on lateral and upper margins long, rather sparse; Costa Rica to Panama; Cecropia petioles; 1.4-1.8 mm (see also subspecies

16. cecropiavorus Wood

15(12). Color black; pronotal punctures moderately large but very shallow; interstrial punctures uniseriate, minute; declivital interstriae 2 strongly narrowed on lower half and depressed; female frons with antennal insertion dorsad of normal position, lower half of frons flattened, yellow, appearing spongy and finely pubescent, with a large, median, black, strongly elevated process from epistoma to center of spongy area occupying median fourth; Guatemala; $1.8 \mathrm{~mm} .$.
17. unipunctatus (Blandford)

- Color brown; pronotal punctures rather deep; interstrial punctures moderately to very coarse; declivital interstriae 2 not depressed or narrowed; female frons devoid of spongy area or elevated median process
16(15). Punctures on elytral declivity poorly defined, not impressed; Costa Rica; Cecropia petioles; $1.7-2.0 \mathrm{~mm}$ 18. cecropii (Schedl)
- Declivital striae and strial punctures feebly but distinctly impressed; Costa Rica; Cecropia petioles; 1.4 mm

19. blandfordi (Schedl)

17(12). Female frons rather coarsely, not closely punctured, pubescence fine, uniformly distributed, rather sparse; punctures coarse, deep; Guatemala to Costa Rica; Plumeria, etc.; $1.4-1.8 \mathrm{~mm}$ (see also 21. striatus (Eggers))
20. venustus Wood

- Female frons rather finely, closely punctured, pubescence uniformly distributed, rather abundant; striae not at all impressed, punctures rather fine, shallow; Costa Rica; Ficus; 1.4-1.9 mm

22. pseudopiceus Wood

$$
\begin{aligned}
& \text { 18(6). Elytral vestiture abundant, long, confused; meso- and metathoracic tibiae } \\
& \text { rather broad, each armed by seven socketed, marginal teeth on distal half ............. } 19
\end{aligned}
$$

- Elytral vestiture sparse, short, in uniseriate strial and/or interstrial rows, often entirely absent on disc; meso- and metathoracic tibiae usually more slender, with three to six socketed, marginal teeth confined to distal fourth21

19(18). Interstrial punctures on 1 and 2 confused, others uniseriate, interstrial setae particularly on and near declivity coarse, blunt, somewhat flattened; surface of pronotum reticulate, with moderately coarse punctures; striae clearly evident, punctures distinctly larger than those of interstriae; Guatemala; 1.6 mm
23. setosus (Blandford)

- All interstrial punctures confused, interstrial setae fine, pointed

20(18). Pronotum shining, obscurely reticulate, punctures deep, coarse, interspaces between punctures about equal in width to diameter of a puncture; elytral punctures rather coarse, deep, strial punctures clearly larger, closer; Costa Rica; Oreopanax; 1.6 mm

- Pronotum surface dull, strongly reticulate, punctures fine, shallow, separated by distances averaging at least twice diameter of a puncture; elytral punctures fine, strial and interstrial punctures distinguished with difficulty; Costa Rica; vine; 1.7 mm

25. hirsutus Wood

21(18). Body stout, 1.9 times as long as wide; pronotum convex, wider than long ( 0.90 times as long as wide); interstrial bristles on alternate, odd-numbered interstriae of declivity, sparse, widely spaced, rather strongly flattened; Panama; 1.0 mm

- Body more slender, 2.2 or more times as long as wide; pronotum at least 1.03 times as long as wide; elytral bristles, when present, more slender, not strongly flattened ..... 22
22(21). Female frons weakly convex to broadly, shallowly concave, vestiture rather uniformly distributed, usually rather inconspicuous; striae usually weakly impressed, punctures much deeper, coarser than those of interstriae ..... 23
- Female frons longitudinally, broadly grooved, lateral margins rather abruptly elevated to conspicuously carinate, vestiture largely confined to tuft at upper limits of sulcus; striae not impressed, strial and interstrial punctures both obscure or of subequal size and not clearly distinguishable ..... 27
23(22). Elytra stouter, 1.3 times as long as wide; mature body color dark reddish brown; strial and interstrial punctures on declivity, rather coarse, deep, subequal in size, confused; Panama; 1.3-1.5 mm 27. venustulus Wood
- Elytra slender, at least 1.5 times as long as wide; mature body color black; strial punctures on declivity in rows, distinctly larger than those of interstriae (all declivital punctures obsolete in most clusiae) ..... 24
24(23). Pronotal and interstrial punctures obsolete, strial punctures very small; pro- notum very strongly reticulate, dull; Costa Rica; Clusia; 1.7-1.9 mm28. clusiae Wood
- Pronotal and interstrial punctures clearly impressed ..... 25a
25a(24). Elytra almost glabrous, two or three setae on odd-numbered interstriae; fronsconvex in both sexes, almost glabrous; anterior fourth of pronotum without in-dications of asperities, punctures on posterior areas rather coarse; Costa Rica;Quercus; 1.6-1.9 mm29. radiatus Wood
Elytra with more abundant vestiture (only on odd-numbered interstriae in col-canus); pronotal punctures smaller; anterior fourth of pronotum with weakasperities (except volcanus)25b
25 b (25a). Striae moderately impressed, strial and pronotal punctures equally coarse,strongly impressed; interstrial punctures oftne subvulcanate or feebly granu-late; female frons convex, usually almost flat on lower half, vestiture fine,sparse, rather short, only slightly more conspicuous than in male; Michoacán toHonduras; Clusia; 1.8-2.9 mm30. clusiacolens Wood
- $\quad$ Smaller; striae feebly or not at all impressed: interstrial punctures never vulca-nate or granulate; female frons concavely impressed, more conspicuouslypubescent26
26(25). Elytra with erect interstrial setae placed at regular intervals on alternate odd interstriae, strial setae minute but present; female frons shallowly concave, concavity ending well below upper level of eyes, a rather large, impunctate callus just above epistoma; Veracruz to Guatemala; Clusia; 1.3-1.6 mm (see also 32. amabilis Wood and 33. canalis Wood)
- Elytra subglabrous, rarely with more than five erect setae on declivity, strial hair always absent; female frons more strongly concave, concavity extending to well above upper level of eves, punctured throughout to epistoma, pubescence on upper margins more conspicuous; Costa Rica: 1.2-1.4 mm

27(22). Larger; pronotum strongly reticulate, dull; pronotal and elytral punctures somewhat larger, more distinctly impressed; female frontal carinae extending from slightly below level of antennal insertion to upper level of eyes; brush of hair near vertex poorly developed; Costa Rica; Oreopanax; 1.5-1.9 mm
35. irazuensis Wood
Smaller; pronotum subshining, rather obscurely reticulate; pronotal and elytral
punctures fine; female frons with lateral ridges or carinae extending well be-
low level of antennal insertion, brush of hair rather well developed; in
Cecropia petioles ......................................................................................................... 28

28(27). Pronotal punctures very slightly smaller; lateral margins of female frons $\begin{aligned} & \text { abruptly elevated, not sharply carinate, crests converging toward a point just } \\ & \text { below upper level of eyes, tuft of hair occupying upper half of impressed area } \\ & \text { comparatively small; Veracruz to Costa Rica; Cecropia; } 0.9-1.1 \mathrm{~mm} \text {.............. }\end{aligned}$
36. parvulus Wood

- Pronotal punctures very slightly larger; lateral margins of female frons acutely carinate, carinae parallel, tuft of hair dense, large, tips of some setae attaining level of antennal insertions; Guatemala to Panama; Cecropia; 0.9-1.1 mm

37. acares Wood

29(1). Anterior tibiae devoid of a minute tooth on posterior face ........................................ 30

- Anterior tibiae armed on posterior face by one or two small teeth just behind tarsal insertion and between inner terminal mucro and first or second lateral tooth 39

$30(29)$. Interstriae 10 narrowly convex on basal third only, not extending behind level
of metacoxae; interstriae almost devoid of punctures; female frons concavely
impressed on lower half, concavity densely, coarsely, almost granulately punc
tured, smooth and shining in central area above, a brush of hair usually
overhanging polished area; Costa Rica; Ochroma; 1.3-1.5 mm .. 38. ochromae Wood

- Interstriae 10 narrowly convex at least to base of declivity
31
$31(30)$. Anterior half of lateral margins of pronotum concavely impressed on a large, subcircular area and ornamented by a dense brush of moderately long, yellow hair; Panama; 2.4 mm 39. culcitatus (Blandford)
- Anterior half of lateral margins of pronotum normal, devoid of unusual pubescence32

32(31). Stout, 2.1 times as long as wide; minute, sparse punctures on posterior pronotal
disc, mostly granulate; female frons with a median elevation; $1.3-1.9 \mathrm{~mm}$ ..... 33

- More slender, 2.3 or more times as long as wide (except 2.1 times in obesus) punctures on pronotal dise not at all granulate; female frons flattened on median area; 1.3-3.5 mm, except schwarzi smaller35

33(32). Male carina not attaining epistomal margin; punctures on pronotal disc larger, deep, close; strial punctures rather coarse, deep; Guatemala; Swietenia 1.8 mm
40. spadix (Blackman)

- Male frontal carina variable; punctures on pronotal disc minute or replaced by granules; strial punctures fine, rather shallow34

34(33). Both male and female with a median carina acutely elevated (broad above) from just above level of antennal insertion to epistomal margin, a coarsely reticulate area above its highest point; female brush on vertex dense, rather long; elytral striae 1 impressed; granules on pronotal disc larger, more numerous; Costa Rica; Swietenia, Cedrela; 1.7-1.9 mm
41. swieteniae (Blackman)

- Neither sex with a carina attaining epistomal margin; female median carina low (often double), beginning well above epistoma, evidently ending near upper level of eyes, devoid of coarse reticulation above carina; elytral striae not impressed; granules on pronotal disc sparse, fine; Costa Rica; Cedrela, Vismia; $1.3-1.5 \mathrm{~mm}$

| - | Interstrial punctures confused, often also confused with striae .............................. 38 |
| :---: | :---: |
| 36(35). | Pronotal dise shining, punctures coarse, deep; both strial and interstrial punctures moderately large, deep; S Florida to Veracruz; Ficus; 1.3-1.6 mm ............. |

| - | Pronotum reticulate; elytra brightly shining, without trace of reticulation; elytral punctures fine, sharply defined; Costa Rica to Panama; Phoebea; 1.9-2.1 mm $\qquad$ 45. piceus (Blandford) |

$38 a(37)$. Body stout, 2.1 times as long as wide; female frons armed by a pair of longitu- dinal carinae extending from epistomal margin to level of antennal insertion, carinae divided epistomal area into equal thirds; Panama; 1.8 mm

- Body 2.4-2.5 times as long as wide; female frons without longitudinal carinae ..... 38b
$38 b(38 a)$. Larger; all strial punctures small but in definite rows; punctures on dise of pro- notum minute, almost obsolete; Costa Rica; Miconia; 3.5 mmSmaller; punctures of striae 1 and 2 small, more or less in rows, all others
confused with those of interstriae; Costa Rica; Alnus; 2.4-2.9 mm ..... 48. alni Wood
$39(29)$. Interstriae 10 acutely convex at least to base of declivity ..... 40
- Interstriae 10 acutely convex only on basal third, carina not extending beyond level of hind coxae ..... 43
40(39). Pronotum wider than long, its anterior margin unarmed ..... 41
- Pronotum longer than wide, its anterior margin armed by a transverse, serrated elevation ..... 42
41(40). Elytra elongate, 1.5 times as long as wide; strial and interstrial hair conspicuous; Costa Rica; Ficus; 1.4-1.6 mm 49. erincophilus Wood
- Elytra stout, 1.2 times as long as wide; elytra essentially glabrous; Guatemala; Ficus; 1.5-1.7 mm 50. ficivorus Wood
42(40). Pronotum 1.02 times as long as wide; striae not at all impressed; elytral surface strongly reticulate, dull; elytra almost glabrous; Michoacán and Puebla to Morelos; Ficus; 1.5-2.0 mm 51. reticulatus (Wood)
- Pronotum 1.2 times as long as wide; striae rather narrowly, deeply impressed; elytral surface smooth, shining; elytral vestiture fine, long; Chiapas to Costa Rica; 1.5-1.7 mm 52. marginatus Wood
43(39). Anterior margin of pronotum sharply elevated, subserrate; pronotum more slender, at least 1.1 times as long as wide ..... 44
- Anterior margin of pronotum unarmed; pronotum as wide or wider than long ..... 52
44(43). Striae on disc and declivity strongly impressed, punctures large, deep; inter-strial punctures small, distinct, uniseriate; elytral vestiture consisting entirelyof uniseriate rows of erect, spatulate, blunt, interstrial bristles; Costa Rica;$1.3-1.7 \mathrm{~mm}$ (see also 54. pelicipennis Schedl, 1.2 mm )53. impressus Wood
- Striae not impressed; vestiture rather fine, elytral bristles not flattened ..... 45
45(44). Body rather slender to stout, not more than 2.4 times as long as wide; sides of pronotum straight or weakly, arcuately inflated on basal half ..... 46
- Body very slender, 2.8 times as long as wide; sides of pronotum conspicuously constricted on basal half ..... 50

46(45). Pronotal asperities exceedingly broad, some a fifth as broad as pronotum, costa arming anterior margin usually an unbroken ridge

- $\quad \begin{aligned} & \text { Pronotal asperities normal, rather narrow, usually not more than one-tenth as } \\ & \text { broad as pronotum, armature on anterior margin serrate or broken ........................ } 48\end{aligned}$

47(46). Strial and interstrial punctures on dise and declivity small, shallow; female frons with a conspicuous, procurved callus near center occupying median twothirds, vestiture above callus rather sparse, short; Costa Rica; Ficus; 1.5-1.8 mm
55. rugicollis (Schedl)

- Strial and interstrial punctures larger, deeper; female frons flattened on a large, circular area, flattened area minutely pilose, margins with a dense row of long hair; Honduras; 1.5-1.7 mm

56. pannuceus Wood

48(47). Larger; declivital striae in obscure rows, interstriae marked by distinct, uniseriate granules; strial and interstrial punctures on disc large, deep, in rows, those of interstriae almost as large as strial punctures; Puebla; 1.7-2.2 mm (see also 58. pelicerinus Schedl, 1.3-1.5 mm)
57. multistriatus (Wood)

- $\quad$ Smaller; declivital punctures confused, devoid of granules; strial and interstrial punctures on disc smaller, not as deep

49(48). Pronotum smooth, shining, with very deep, close punctures separated by distances about equal to one-fourth diameter of a puncture; female frons abruptly concave on central half, impression continuing as a broad trough to epistoma, central area pilose, hair in dense marginal fringe short; Costa Rica; 1.5-1.8 mm
59. pubescens Wood

- Pronotum reticulate, dull, punctures rather deep, moderately close, separated by distances averaging about half diameter of a puncture; female frons shallowly, evenly concave, pilose in central area, hair in marginal fringe long; Nayarit; Inga; 1.3-1.7 mm

60. ingavorus Wood

50(45). Pronotum reticulate, subshining, punctures on dise minute; elytral vestiture finer, shorter; female frontal vestiture fine, sparse, uniformly distributed; Panama; Clusia; 1.7-1.9 mm
61. proximus Wood

- Pronotum smooth or reticulate, punctures on disc moderately coarse; elytral vestiture longer, conspicuous; female frontal vestiture abundant, long, in Ficus51

51(50). Interstrial bristles widely spaced within each row, developed only on alternate, odd-numbered interstriae; interstrial punctures moderately large; central area of female frons pubescent; Jalisco to Honduras; 1.0-1.4 mm
62. tenuis (Wood)

- Interstrial bristles closely set, on all interstriae; interstrial punctures very fine; central area of female frons glabrous, shining, Oaxaca to Guatemala; 1.2-1.4 mm 63. micidus Wood

52(43). Body stout, 2.0 times as long as wide; pronotal dise smooth, shining, punctures rather coarse; interstrial bristles coarse, long, spatulate; Costa Rica; Ficus; $1.2-1.3 \mathrm{~mm}$
64. exiguus Wood

- Body slender, 2.4 times as long as wide; pronotal dise reticulate, punctures fine, interstrial bristles fine, not flattened

53(52). Strial and interstrial punctures rather coarse, deep; female frontal vestiture rather sparse; Costa Rica; Drimys, Miconia; 1.4-1.6 mm 65. pumilus Wood

- Strial punctures fine, shallow, interstrial punctures minute to obsolete; female vestiture abundant on upper margins of frons

54(53). Larger; punctures of pronotum and elytra shallow, not always clearly defined; declivital punctures on elytra minute, in definite rows, interstrial punctures sometimes obsolete; female frons flat; Veracruz; 1.0-1.3 mm
66. obscurus (Wood)

- Smaller; punctures of pronotum and elytra more sharply impressed; declivital punctures more numerous, not always in rows; female frons impressed, lateral margins distinctly elevated; Panama; 0.9-1.0 mm

67. nanellus Wood

## 1. Scolytodes glabrescens Wood

Prionosceles glaber Wood, 1961 (nec Eichhoff, 1867). Great Basin Nat. 21:102 (Holotype, male; Summit, Canal Zone, Panama; U.S. Nat. Mus.)
Scolytodes glabrescens Wood. 1971, Great Basin Nat. 31:152 (Replacement name)
Diagnosis.- This species is allied to atratus (Blandford), but it is easily distinguished by the glabrous pronotum and elytra, and by the confused strial and interstrial punctures.

Male.- Length 2.4-3.4 mm, 2.1 times as long as wide; color black, antennae and legs somewhat lighter.

Frons broadly, uniformly convex, with a slight transverse impression just above epistomal margin; surface reticulate, punctures rather fine, deep, moderately close, finer and more abundant on impressed area; vestiture fine, short, inconspicuous except for a rather dense brush of moderately long yellow hair directed orad. Eye elongate, entire; finely granulate. Antennal club small, with two weakly procurved sutures indicated by rows of setae.

Pronotum about as long as wide; sides straight and parallel, then abruptly narrowed to rather narrowly rounded anterior margin; basal and lateral margins marked by a conspicuous fine raised line; rather strongly arched from basal to anterior margin; surface subshining, obscurely, very finely reticulate; punctures very fine, deep, moderately abundant, appearing subcrenulately wrinkled on anterior fourth. Glabrous.

Elytra 1.3 times as long as wide, about 1.4 times as long as pronotum; sides straight and parallel on basal two-thirds, rather abruptly, broadly rounded behind; striae obscurely indicated on base of disc, punctures very fine and confused posteriorly, with abundant, confused, interstrial punctures. Interstriae 10 costiform to declivity, interstriae 9 elevated near declivital base. Declivity steep, convex; positions of striae 1 and 2 impressed, interstriae 1,2 , and 3 convex on middle third; all
punctures minute, deep, confused. Elytra entirely glabrous.

Female.-Similar to male except frons broadly flattened on lower two-thirds, impressed just above epistoma, and bearing a conspicuous brush of rather abundant, moderately long, fine, yellow hair uniformly distributed over entire flattened area from just below upper level of eyes to epistomal margin; impressions and elevations of elytral declivity obscure.

Distribution.- Costa Rica to Colombia and Venezuela.

COSTA RICA: Turrialla, Cartago, 5 -VII- $63,700 \mathrm{~m}$, No. 19, S. L. Wood. Panama: Cerro Campana, Panama, 26-VII-66, 1000 m , No. 33, S. L. Wood; Ft. Clayton, Canal Zone, $22-\mathrm{XII}-63,30 \mathrm{~m}$, No. 322, S. L. Wood; Gatín Dam, Canal Zone, 31-XII-6.3, 15 m , No. 362, S. L. Wood; Limon Bay, Canal Zone, 30-XII-63, No. 356, S. L. Wood: Summit, Canal Zone, X-46, No. 937 and IX46, No. 810, N. L. H. Krauss. All from petioles of fallen Cecropia leaves. OTHER COUNTRIES: Colombia, Venezuela.
Host.- Cecropia spp.
Brology.- This monogamous species infests recently fallen Cecropia leaf petioles where adult and larval mines are made in the large, soft pith. As with many other species in this genus eggs are scattered in the frass of the irregular parent gallery. The larvae extend the parental chamber. At times the greater portion of pith in the basal half of a petiole is almost entirely consumed.

Notes.- The above treatment was based on the holotype of glaber (Wood) and 37 other specimens.

## 2. Scolytodes maurus (Blandford)

Prionosceles maurus Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):178 (Lectotype, male; Pantaleon, Guatemala; British Mus. Nat. Hist., present designation)
Hexacolus ellipticus Eggers, 1934, Ent. Blätt. 30:50 (Holotype, male; Turrialba, Costa Rica; Institut für Phlanzenaschutzforschung Kleinmachnow); Wood, 1975, Great Basin Nat. 35:22. Synonymy

Diagnosis.- This species is allied to atratus (Blandford), but it is distinguished by the much smaller size, the habits, and other characters summarized in the above key.

Male.- Length $1.6-2.1 \mathrm{~mm}, 2.0$ times as long as wide; color very dark brown.

Frons weakly convex; surface coarsely subreticulate, punctures coarse, deep, moderately close; vestiture inconspicuous except on epistomal area.

Pronotum 0.94 times as long as wide; widest at base, sides feebly arcuate, converging slightly on basal two-thirds, rather broadly rounded in front; anterior third minutely asperate, asperities low, rather widely spaced; surface reticulate, punctures rather fine, spaced by distances equal to about two to four diameters of a puncture, much smaller in asperate area. Glabrous.

Elytra 1.2 times as long as wide; sides almost straight and parallel on basal half, rather broadly rounded behind; striae 1 weakly, others not impressed, punctures small, moderately deep, mostly in definite rows; interstriae almost three times as wide as striae, almost smooth, punctures almost uniseriate to moderately confused, irregular in size within a row, fine to moderately coarse. Declivity convex, rather steep; striae slightly impressed, strial and interstrial punctures more definitely uniseriate; interstrial punctures often indefinitely, very feebly granulate. Vestiture consisting of interstrial rows of erect bristles, spacing of bristles between rows and within a row about equal to length of a bristle.

Female.- Similar to male except frons shallowly to rather deeply concave on lower two-thirds (variable within a series), size and density of frontal punctures varying within series; frontal vestiture of moderately long, sparse, yellow hair.

Distribution.- Veracruz and Oaxaca to Panama and Venezuela.

MEXICO: Chiapas, Oaxaca, Veracruz. GUATEMala: Quezaltenango, Esquintla. HONDURAS: Cortez, Morazán. COSTA RICA: Limon, Puntarenas, San José. PANAMA: Panama (Cerro Campana). VENEZUELA: Miranda (El Laurel near Caracas).

Host.- Cecropia spp.
Biology.- The petioles of fallen Cecropia leaves are selected for attack. The entrance holes commonly were found on the petiole surface that attached the leaf to the tree; the
tunnels usually were in the hardened basal portion, rarely more than 5 cm from the base. The habits evidently were typical of the genus.

Notes.- The above treatment was based on the three syntypic specimens in Blandford's original series and on 122 other specimens. Because a type has not been designated, I here designate the first male in Blandford's series, from Pantaleon, as the lectotype for his Prionosceles maurus; this specimen previously was labeled as the type and has been regarded as the type of the species.

## 3. Scolytodes atratus atratus (Blandford)

Prionosceles atratus Blandford, 1897, Biol. Centr. Amer., Coleopt. $4(6): 178$ (Lectotype, male; Senahú, Vera Paz, Guatemala; British Mus. Nat. Hist, present designation)
Diagnosis.- This species is allied to glabrescens Wood, but it is easily distinguished by the regularly striate elytra, the vestiture and other characters.

Male.- Length $2.4-3.3 \mathrm{~mm}, 2.0$ times as long as wide: color black.

Frons convex above, impressed on lower half except median third above level of antennal insertions; surface shining, coarsely, deeply punctured, punctures moderately close above, dense on lower half; pubescence restricted to epistomal area.

Pronotum 1.02 times as long as wide; outline and asperities as in maurus; surface finely reticulate, subshining, punctures fine, deep, moderately close, obsolete in asperate area. Glabrous.

Elytra 1.2 times as long as wide; sides almost straight and parallel on basal two-thirds, very broadly rounded behind; striae 1 strongly, others moderately impressed, punctures fine, close, rather shallow; interstriae at least twice as wide as striae, almost smooth, shining, punctures very fine, uniseriate except slightly confused on 2 , becoming finely granulate near declivity. Declivity broadly convex, rather steep; essentially as on disc, interstriae 1 indistinctly impressed; interstriae uniseriately granulate, granules fine, rounded. Vestiture confined to declivity, consisting of uniseriate rows of fine, interstrial hair; each hair slightly shorter than distance between rows or between setae in a row.

Female.-Similar to male except frons abruptly, transversely, strongly impressed just below upper level of eyes to epistoma, a median callus on lower half of impressed area, impressed area clothed by moderately abundant, fine, long, yellow hair.

Distribution.- Veracruz to Honduras.
MEXICO: Chiapas, Oaxaca, Veracruz. GUATEMALA: Quezaltenango, Vera Paz. HONDURAS: Cortez, Morazán.

Hosts.- Cecropia spp.
Biology.- Recently fallen petioles were selected for attack. The tunnels most commonly were found in the basal half of the petiole, although occasional petioles were almost completely consumed. The male beetle evidently always constructed the entrance tunnel to the soft pith, where an irregular cavity was formed. The female then excavated one or more tunnels from a few millimeters in length up to half the length of the petiole. She distributed a few eggs at random, often mixed with frass, along the tunnel. The larvae extended the parental galleries, often consuming almost the entire pith region.

Notes.- The above treatment was based on Blandford's seven syntypes and on 126 other specimens. Because a type has not been selected, I here designate a male from Senahú as the lectotype of Prionosceles atratus Blandford. This specimen was labeled "type" and has been regarded as the type for many years.

As indicated in the above key, this species is divided into northern and southern geographical races on the bases of distinct differences in average size, in surface sculpture of the pronotum, and in very slight differences in sculpture of the elytral declivity. The minute differences between specimens from these areas and the absence of specimens from Nicaragua (due to lack of collecting) suggest the advisability of recognizing subspecies, at least until intergradation can be demonstrated and studied.

## 4. Scolytodes atratus panamensis (Wood)

[^7]Diagnosis.- Although intergradation of this taxon with atratus (Blandford) has not
been found, the geographical distribution, host, and habits very strongly suggest they are subspecies. They may be distinguished by characters mentioned in the above key.

Distribution.- Costa Rica to Panama.
COSTA RICA: Cartago, Limón, Puntarenas, San José provinces. PANAMA: Canal Zone and Panama.

Host.- Cecropia spp.
Biology.-Similar to a. atratus above. It is very abundant.

Notes.-- The above treatment was based on the type series of 14 specimens, and on 115 other specimens.

## 5. Scolytodes plumeriae Wood

 Figs. 17, 26Scolytodes plumeriae Wood, 1969, Brigham Young University Sci. Bull., Biol. Ser. $10(2): 17$ (Holotype, female, Playa del Coco, Guanacaste, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from phoebeae Wood by the pronotal surface being smooth and shining, by the pronotal punctures being coarse and deep, and by the female frontal vestiture extending higher on the vertex, more abundant and longer.

Female.- Length $1.9-2.7 \mathrm{~mm}, 2.0$ times as long as wide; color very dark brown, almost black.

Frons flattened from vertex to epistoma, lateral margins feebly raised below level of antennal insertion; surface densely, rather closely punctured, central area impunctate and very weakly elevated, punctures decreasing in size toward this impunctate area; vestiture very fine, moderately abundant, except glabrous in impunctate area, pubescent area scarcely extending above upper level of eyes.

Pronotum 1.0 times as long as wide; sides almost straight and parallel on basal half, rather narrowly rounded in front; surface smooth and shining, with minute points and with coarse, deep, close punctures, many punctures separated by distances less than diameter of a puncture; lateral and anterior surface somewhat wrinkled; glabrous.

Elytra 1.2 times as long as wide, 1.2 times as long as pronotum; sides almost straight and parallel on basal half, rather broadly rounded behind; striae feebly impressed, punctures small, impressed; interstriae about three times as wide as striae, surface smooth, with minute points, punctures almost as large as
those of striae but not as deep, confused. Declivity steep, convex; striae 1 impressed, all punctures reduced in size, punctures on interstriae 1 and 2 uniseriate, punctures lateral to striae 2 confused. Glabrous.

Male. - Similar to female except frons convex, with a transverse impression along epistoma and continuing dorsad in lateral areas to level of antennal bases; frontal punctures fine, sparse, vestiture scanty, inconspicuous.

Distribution.- Guatemala to Costa Rica.
guatemala: Rodeo, Esquintla, 4-VI-64, 150 m , No. 677. Plumeria, S. L. Wood. COSTA RICA: Playa del Coco, Guanacaste, 11-V11-66, 1 m , No. 20, Plumeria rubra, S. L. Wood.

Host.- Plumeria rubra.
Habits.- This aggressive species is capable of killing healthy branches of its host, although cut or unthrifty material is usually selected for attack. The habits are essentially as in phoebeae. The entire life cycle can be completed in less than 20 days.

Notes.- The above treatment was based on the type series of 79 specimens and on 17 other specimens.

## 6. Scolytodes phoebeae Wood

Scolytodes phoebeae Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):16 (Holotype, female. Tapantí, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- Allied to cecropicolens Wood, but larger, the anterior third of pronotum entirely devoid of asperities, and the female frons ornamented by long hair. It is much more closely related to plumeriae Wood.

Female.- Length $2.0-2.6 \mathrm{~mm}, 2.0$ times as long as wide; color dark brown.

Frons flattened from vertex to epistoma; lateral margins below level of antennal bases weakly elevated; central area on lower half impunctate, very slightly raised, marginal areas from near epistoma to vertex closely, finely punctured and ornamented by a dense brush of long, yellow hair, hair longer and more abundant above, tips of longest setae on vertex attaining level of antennal bases; premandibular epistomal lobe well developed.

Pronotum 0.95 times as long as wide; widest at base, sides almost straight on basal half and converging slightly, then rounded toward the narrowly rounded anterior margin; entire surface reticulate, finely
punctured, punctures separated from one another by 2 or more times their own diameters.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal half, rather narrowly rounded behind; striae not impressed, punctures moderately coarse, not deep; interstriae about three times as wide as striae, punctures almost as large as those of striae, confused. Declivity rather steep, convex; strial punctures slightly smaller and deeper than on disc; interstrial punctures much smaller than those of striae, almost uniseriate on 2; 10 acutely convex from base to level of basal margin of sternum 5. Glabrous, except a few minute hairs on costal margin.

Male. - Similar to female except frons convex above, becoming irregularly flattened below, a weakly transverse impression just above epistoma, glabrous.

Distribution.-Costa Rica.
COSTA RICA: Tapantí, Cartago, 24-X-63, 1300 m , No. 241. Phoebea mexicana, S. L. Wood.

Biology.-As in most other Scolytodes species, this species is monogamous. The adult male constructs an entrance tunnel and begins a nuptial chamber. Both male and female enlarge the oval cavity to about 3-5 mm wide and about $5-8 \mathrm{~mm}$ or more long. It is entirely within the thin bark, not engraving the wood at all; only the paper-thin, smooth, outermost layer of bark remains to conceal the tunnel. Eggs are scattered indiscriminately in the chamber; the young larvae feed along the margins of the chamber through the first and second instars, enlarging it somewhat. While the young larvae feed, the parent beetles bore from the phloem through the woody tissues to the large pith area. In the pith they construct a new chamber that is usually slightly larger than the first. Third instar larvae (as judged by their size) migrate to the pith chamber, where they feed until pupation occurs. Young adults may occur in pith, xylem, or phloem tissues, but most of them remain in the pith until it is entirely consumed. The infested branch studied was cut by me on 17 September; attack occurred after that date, and most of the brood had matured by 24 October.

Notes.- The above treatment was based on the type series of 153 specimens.

## 7. Scolytodes minutissimus Schedl

Scolytodes minutissimus Schedl, 1952, Dusenia 3:355 Holotype, female; Hamburgfarm on Río Reventazon, Limón, Costa Rica; Schedl Coll.)
Diagnosis.- This species is distinguished from phoebeae Wood by the much smaller size, by the minute pronotal and elytral punctures, and by the different female frons.

Female.- Length $1.2 \mathrm{~mm}, 2.1$ times as long as wide; yellowish brown (probably not fully colored).

Frons with eyes separated by 1.7 times width of an eye, broadly convex, median fourth with a longitudinal, smooth, shining callus from level of antennal insertion twothirds distance to upper level of eyes, marginal areas surrounding callus weakly impressed and obscurely punctured, impressed area occupying about half of distance from callus to inner margin of eye; remaining area smooth, shining, with very sparse, fine punctures; vestiture confined to impressed area, of moderately abundant, rather short hair; longest setae about equal in length to half width of eye.

Pronotum 0.88 times as long as wide; widest at base, sides feebly converging on basal half, rather broadly rounded in front; surface shining, almost smooth, very obscurely subreticulate near obscure summit; punctures minute, shallow, widely spaced. Glabrous.

Elytra 1.3 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, rather narrowly rounded behind, surface smooth, shining; striae not impressed, punctures minute, close, in irregular rows; interstriae more than six times as wide as striae, punctures sparse, minute, uniseriate on basal half, confused on 1 and 2 toward declivity. Declivity convex, rather steep; punctures on lower half deeper than on disc and uniseriate. Very minute interstrial setae sparsely scattered on declivity.

Distribution.- Costa Rica.
COSTA RICA: Hamburgfarm on Río Reventazon, Limón, im nest von Giton hamatum, F. Nevermann.

Notes.- The above treatment was based on the holotype.

## 8. Scolytodes levis (Blackman)

Ctenophorus lacvigatus Chapuis, 1869 (nec Ferrari, 1867), Synopsis des Scolytides, p. 49 (Syntypes, males; Colombie; Brussels Mus.). Preoccupied
Hexacolus lecis Blackman, 1943, Proc. U.S. Nat. Mus. $94(3174): 382$ (Holotype, female; Paraiso, Canal Zone, Panama); Wood, 1977, Great Basin Nat. 37:517. Synonymy
Scolytodes chapuisi Wood, 1977, Great Basin Nat. 37:210 (Replacement name for lacvigatus Chapuis); Wood, 1977, Great Basin Nat. 37:517. Synonymy
Diagnosis.- This species is distinguished from the remotely allied phoebeae Wood by the smaller, more slender form, by the uniseriate interstriae, and by numerous other characters described below.

Female.- Length $1.7-2.2 \mathrm{~mm}, 2.2-2.3$ times as long as wide; color dark reddish brown.

Frons moderately convex; median fourth from epistoma on lower two-thirds below upper level of eyes a smooth, brightly shining, weakly elevated callus, its outline moderately constricted just above epistoma; median three-fourths (except for callus) finely, rather closely punctured form epistoma to vertex (one-fourth of punctured area above eyes); vestiture of rather long, moderately abundant, reddish yellow hair; lateral and dorsal areas reticulate.

Pronotum 1.0 times as long as wide; about as in cecropii Schedl except less strongly convex, less strongly reticulate, with no indication of asperities on anterior slope.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; very similar to cecropii except strial punctures slightly larger, more distinct, interstrial punctures almost uniseriate, rather indistinct, declivity smoother, with punctures more distinct. Glabrous.

Male.- Similar to female except frons uniformly convex and reticulate, without special sculpture or setae.

Distribution.- Panama to Venezuela.
PANAMA: Paraiso, Canal Zone, 26-1-11, E. A. Schwarz. VENEZUELA: Colonia Tovar, El Laurel (12 km SW Caracas), and Rancho Grande (Pittier National Park) in Aragua.

Host.-Cecropia sp.
Biology.- All specimens from Venezuela were removed from the petioles of fallen Cecropia leaves.

Notes. - The holotype and 113 other specimens were examined.

## 9. Scolytodes amoenus Wood

Scolytodes amoenus Wood, 1967, Great Basin Nat. 27:128 (Holotype, female; 35 km N Juchitlán, Jalisco, Mexico; Wood Coll.)
Diagnosis.- Superficially, this species resembles multistriatus Wood, but it is brightly shining, the declivity is more gradual, the female frons is entirely different, and interstriae 10 is acutely elevated to the declivity. Among species with an asperate anterior slope of the pronotum, continued 10th elytral interstriae, and a tubercle on the posterior face of the front tibiae, this species is unique. The large size, the multistriate elytra, and the unique female frons also help to distinguish this unusual species.

Female.- Length $1.9-2.3 \mathrm{~mm}, 2.2$ times as long as wide; color of basal third of pronotum, most of elytra, and most of body yellowish brown, with head, anterior two-thirds of pronotum, all margins of each elytron, and some parts of meso- and metasternum dark brown (variable in series).

Frons flattened from just above upper level of eyes to epistoma; most of area between eyes occupied by a very finely granulate, perfect circle extending from upper level of eyes to epistoma; lower half of circle bearing on its lower half a smooth, shining, transverse, procurved band with small, median, orad extension, this area about equal to half width of circle; area outside of circle rather coarsely, very closely punctured; vestiture consisting of equally long, fine, plumose setae on a continuous band surrounding circular area, numerous additional setae along epistoma; central area glabrous.

Pronotum 1.1 times as long as wide; widest at base, sides very feebly arcuate, almost straight, converging anteriorly very slightly on basal two-thirds, rather narrowly rounded in front; indefinite summit near middle, anterior fourth finely asperate; anterior margin armed by a continuous ridge; posterior areas obscurely subreticulate, coarsely, deeply, closely punctured, punctures separated by slightly less than their own diameters. Glabrous except near lateral and anterior margins.

Elytra 1.3 times as long as wide, 1.2 times as long as pronotum; sides almost straight and parallel on basal half, rather narrowly
rounded behind; elytra with basal margin marked by a fine, raised line; striae 1 weakly, others not impressed, punctures rather fine, deep; interstriae shining, one and one-half times as wide as striae, punctures rather fine, deep, rather abundant, confused. Declivity convex, steep; striae 1 strongly impressed; all punctures reduced, those of striae little larger than abundant interstrial punctures. Glabrous except at sides.

Male.- Similar to female except frons convex, with a transverse impression just above epistoma, surface reticulate with coarse deep punctures above, a few granules below.

Distribution.- Jalisco to Tamaulipas.
MEXICO: Jalisco: 35 km N Juchitlán, 3-VII-65, 1300 m, No. 177 Ficus, S. L. Wood. Tamaulipas: Bocatoma, 7 km SE Gómez Farías, 25-111-78, E. G. Riley.

Biology.- This species infested the phloem tissues of unthrifty and cut branches of a native fig tree.

Notes.- The above treatment was based on the type series of 68 specimens.

## 10. Scolytodes lepidus Wood

Scolytodes lepidus Wood, 1975, Great Basin Nat. 35:27 (Holotype, female; 33 km or 21 miles N Juchitlán, Jalisco, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from amoenus Wood by the slightly larger average size, by the slightly larger elytral punctures, by the presence of a few elytral setae, particularly along sides, and by the very different female frons.

Female. - Length $1.8-2.3 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown, base of pronotum usually pale.

Frons broadly flattened from epistoma to vertex, almost smooth, upper half and sides below coarsely, closely punctured and pubescent, median third on lower half slightly elevated, smooth, shining, impunctate, glabrous; vestiture long, moderately abundant, more widely distributed than in amoenus.

Pronotum 1.0 times as long as wide; as in amoenus except discal area reticulate (smooth to subreticulate in amoenus) and moderately pubescent at lateral margins (almost glabrous in amoenus).

Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; as in amoenus except
strial and interstrial punctures larger, more completely confused, and lateral areas with sparse setae (entirely glabrous in amoenus).

Male.- Similar to female, with frons similar to male amoenus except more coarsely punctured, more protuberant in median area, with no granules.

Distribution.- Jalisco.
MEXICO: Jalisco: 33 km or 21 miles N Juchitlán, 3 -VII-65, 1300 m , No. 177, Ficus, S. L. Wood.

Biology.- Specimens were taken from the same branches as the type series of amoenus.

Notes.- The above treatment was based on the type series of 27 specimens.

## 11. Scolytodes genialis Wood

Scolytodes genialis Wood, 1975, Great Basin Nat. 35:27 (Holotype, female; Laguna Santa María, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from lepidus Wood by the absence of punctures in the asperate area of the pronotum and by the much finer punctures on the pronotal disc and on the elytra.

Female.- Length $1.8-2.1 \mathrm{~mm}, 2.3$ times as long as wide; color light brown, anterior half of pronotum darker.

Frons as in lepidus except vestiture finer, very slightly shorter. Pronotum as in lepidus except punctures very fine, shallow. Elytra as in lepidus except strial punctures fine, shallow, in definite rows, interstrial punctures very small, confused, striae 1 not impressed on declivity, vestiture on sides of elytra minute.

Male.- Similar to female except frons as in male lepidus.

Distribution. - Nayarit to Jalisco.
MEXICO: Jalisco: 24 km 5 Mazamitla, 22 -VI-65, Ficus, S. L. Wood. Nayarit: Laguna Santa María, 7-VII65, 900 m , No. 197, Ficus, S. L. Wood.

Biology.- All specimens were taken from branches of a Ficus with yellowish bark.

Notes. - The above treatment was based on the type series of 12 specimens.

## 12. Scolytodes perditus Wood

Scolytodes perditus Wood, 1967, Great Basin Nat. 27:I23 (Holotype, female; Fort Clayton, Canal Zone, Panama; Wood Coll.)
Diagnosis.- This species is distinguished from cecropicolens Wood by the more slender body form, by the less deeply impressed,
finer punctures on pronotum and elytra and, in the female, by the dense, long brush of frontal hair arising above the eyes.

Female.- Length $1.6-2.1 \mathrm{~mm}, 2.1$ times as long as wide; color yellowish brown, anterior fourth of prothorax darker.

Frons flattened from well above upper level of eyes to epistoma, with low, submarginal, longitudinal carinae extending from epistoma about half distance to upper level of eye; central area minutely granulate, lateral areas with a few punctures; vestiture consisting of abundant, coarse, long, subplumose setae mostly arising above eyes, none as low as level of antennal bases, some setae sufficiently long to reach epistoma.

Pronotum 1.1 times as long as wide; widest at base, sides almost straight, converging very slightly anteriorly, rather narrowly rounded in front; slightly less than anterior half very finely, closely asperate; posterior area reticulate, punctures rather fine, shallow. Glabrous.

Elytra 1.2 times as long as wide, 1.2 times as long as pronotum; sides straight and parallel on slightly more than basal half, rather narrowly rounded behind; striae not impressed, punctures small, sharply but not deeply impressed, punctures almost indistinguishable from similar, abundant, confused, interstrial punctures; surface almost smooth, shining. Declivity convex, rather steep; strial punctures deeper than on disc, not reduced; interstrial punctures distinctly smaller, uniseriate except near upper area. Vestiture restricted to a few setae on sides.

Male. - Similar to female except frons convex, with a transverse impression just above epistoma but interrupted by a small subcarinate median elevation; surface smooth, shining, punctures rather coarse, deep; strial punctures on disc deeper and somewhat larger than those of striae.

Distribution. - Panama.
PANAMA: Fort Clayton, Canal Zone, 22-XII-63, 30 m, No. 321, Cecropia, S. L. Wood.

Biology.- Phloem tissues in the branch terminals were infested by this species within a few centimeters of the tip in a broken limb.

Notes. - The above treatment was based on the type series of 18 specimens.

## 13. Scolytodes cecropicolens Wood

Scolytodes cecropicolens Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):16 (Holotype, female; Peralta, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- In size and proportions this species is more nearly similar to maurus (Blandford) than to other species known to me, but tibial and other characters are very different.

Female.- Length 1.9-2.2 mm, 1.9 times as long as wide; color dark brown or medium brown, with marginal areas darker.

Frons rather narrowly flattened below upper level of eyes, median third on lower twothirds of flattened area rather abruptly impressed, impression wider below and less definite; lateral margins indefinitely elevated below level of antennal insertion; surface reticulate above, subreticulate in impressed area, punctures coarse, sparse, sharply defined but not very deep; vestiture minute, inconspicuous, a few longer hairlike setae on epistoma.

Pronotum 0.96 times as long as wide; widest at base, sides very slightly arcuate, converging slightly to subabrupt anterolateral angles, rather narrowly rounded in front; anterior third feebly asperate; surface reticulate, punctures rather coarse and separated by more than their own diameters, much finer anteriorly, continuing to anterior margin. Vestiture minute, appearing glabrous.

Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae feebly if at all impressed, punctures rather coarse, moderately deep; interstriae slightly more than twice as wide as striae, weakly convex, punctures almost as large as those of striae, those on 2 and 4 confused on basal half, almost uniseriate elsewhere. Declivity convex, rather steep; punctures of striae and interstriae smaller, not as deep, and less sharply defined than on disc. Vestiture consisting of rows of short interstrial hair; very minute strial setae visible toward base of elytra.

Male.- Similar to female except frons convex, with a slight transverse impression just above epistoma.

Distribution.- Costa Rica.
COSTA RICA: Peralta, Cartago, 10 -III-64, 500 m , No. 464, Cecropia, S. L. Wood.

Biology.- This species infested phloem tissues in the terminal ends of branches of a cut tree.

Notes. - The above treatment was based on the type series of 28 specimens.

## 14. Scolytodes costabilis Wood

Scolytodes costabilis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):13 (Holotype, female; Lago Catemaco, Veracruz, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from melanocephalus Blandford by the different female frontal sculpture, by the very fine punctures on the pronotal disc, and by the very small strial punctures.

Female.- Length $1.8-2.0 \mathrm{~mm}, 2.6$ times as long as wide; color brown.

Frons rather broadly flattened from epistoma to vertex; a pair of low, subparallel, longitudinal carinae from level of antennal insertion to epistomal margin; surface smooth and shining above level of antennal insertion, a row of punctures around margin; feebly bisulcate between carinae, finely reticulatepunctate in sulci, smooth and shining between; vestiture of long, yellow hair on margins above, tips of longest setae reach level of antennal insertion, sulci on lower third with fine, short hair.

Pronotum 1.1 times as long as wide; sides straight on basal two-thirds, converging very slightly to anterolateral angles, broadly rounded in front; surface reticulate, anterior fourth rather strongly declivous and finely asperate, fine, almost obsolete punctures behind each asperity; punctures on posterior areas very small, shallow, moderately close. Glabrous.

Elytra 1.4 times as long as wide, 1.2 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; basal margins not carinate, abrupt; striae not impressed, punctures very fine, distinctly impressed, spaced within a row by about twice diameter of a puncture; interstriae smooth, shining, punctures very fine, three or more times as wide as striae, uniseriate except moderately confused in some specimens. Declivity steep, convex; sculpture essentially as on disc.

Distribution.- Veracruz.

MEXICO: Veracruz: Lago Catemaco, 16-20-V1-69, 1-3-V-69, D. E. Bright.

Notes.- The above treatment was based on the type series of five females.

## 15. Scolytodes melanocephalus (Blandford)

Hexacolus melanocephalus Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):181 (Lectotype, female; Cerro Zunil, Guatemala; British Mus. Nat. Hist., present designation)
Diagnosis.- This species was placed in the key near cecropiavorus Wood, although it might just as easily have been placed near schwarzi Hopkins or perhaps even amoenus Wood. Although the true relationships of this species are not entirely clear, it is easily recognized by the very distinctive sculpture of the female frons.

Female.- Length $1.7 \mathrm{~mm}, 2.25$ times as long as wide; color brown.

Frons flattened, lateral thirds armed by a pair of carinae beginning just below level of antennal insertion, obliquely diverging to near lateral margin, ending midway between level of antennal insertion and upper level of eye, a strong, rather short median carina extending from this level to vertex; surface obscured by glue on type but evidently smooth and finely punctured; lateral margins rather sparsely pubescent much as in cecropiavorus.

Pronotum about 1.0 times as long as wide; sides almost straight and parallel on basal half, rather broadly rounded in front; anterior third very finely asperate, but with punctures intermixed to anterior margin; posterior areas reticulate, dull, coarsely, rather deeply, closely punctured. Evidently glabrous.

Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, rather broadly rounded behind; striae not impressed, punctures moderately large, rather deep; interstriae twice as wide as striae, almost smooth, punctures slightly smaller and not as deep as those of striae, uniseriate, as closely spaced as those of striae. Declivity convex, rather steep; striae 1 and 2 slightly impressed; all punctures slightly smaller, but similar to declivity. Glabrous.

Distribution.- Guatemala.
GUATEMALA: Cerro Zumil, 4-5000 ft (1300-1700 m), G. C. Champion.

Notes.- The above treatment was based on two syntypes. This species was based on three syntypes from Cerro Zunil; of these, one is missing from its pin. The first syntype, a female, is here designated as the lectotype of Hexacous melanocephalus Blandford. For many years it has borne a type label and has been considered to be the type.

## 16. Scolytodes cecropiavorus Wood

Scolytodes cecropiavorus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):17 (Holotype, female; San lgnacio de Acosta, San José, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from cecropii Schedl by the distinctly impressed strial and interstrial punctures, by the shining male frons with fine punctures, and by the more widely separated female frontal carinae.

Female.- Length $1.4-1.8 \mathrm{~mm}, 2.2$ times as long as wide; color very dark brown.

Frons flattened from vertex to epistoma, divided on lower half into almost equal thirds by a pair of prominent, subparallel, longitudinal carinae; surface finely, rather closely punctured, and punctures somewhat sparse between carinae; lateral and upper areas ornamented by a rather sparse tuft of fine, long, yellow hair.

Pronotum 1.0 times as long as wide; widest near base, sides weakly arcuate, converging very slightly to anterior fourth, then rather narrowly rounded in front; surface reticulate, with fine, rather sparse punctures. Glabrous.

Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae 1 feebly, others not at all impressed, punctures small, shallow; interstriae almost three times as wide as striae, obscurely marked by minute points and lines, punctures fine, obscure, uniseriate. Declivity moderately steep, convex; strial and interstrial punctures obscurely indicated. Glabrous, except for a few setae along costal margin.

Male. - Similar to female except frons evenly, rather weakly convex, with a weak transverse impression just above epistomal process, surface subreticulate above, subshining below, glabrous, except a few setae near epistoma.

Distribution.- Costa Rica.
COSTA RICA: San lgnacio de Acosta, San José, 5-V11$63,1500 \mathrm{~m}$, No. 36; Río Damitas, Dota Mits., San José, 22-VII-63, 250 m , No. 130; Rincón de Osa, Puntarenas, II-VIII-66, No. 58; all from the same host, by S. L. Wood.

## Host.- Cecropia peltata.

Biology. - This species infested recently fallen leaf petioles of the host tree. The tunnels were immediately below the epidermal layer.
Notes.- The above treatment was based on the type series of 33 specimens. Two distinct geographical races of this species are known.
Scolytodes c. acuminatus Wood (Brigham Young Univ. Sci. Bull., Biol. Ser., vol. 10, pt. 2:17, 1969, female holotype, Tapantí, Cartago, Costa Rica, 24-X-63, 1300 m , No. 207, S. L. Wood) was taken from the same host and has similar habits. In this race the elytral apex is strongly acuminate and the male frons is more strongly convex. Intergradation between the two forms could not be demonstrated with the limited material at hand.
Scolytodes c. punctifer Wood (Brigham Young Univ. Sci. Bull., Biol. Ser., vol. 10, pt. 2:18, 1969; male holotype, Gatun Dam Canal Zone Panama, 31-XII-63, 15 m, No. 361, S. L. Wood) was taken from a different species of Cecropia and has similar habits. This subspecies is of the same size and proportions as c. cecropiavorus, but the elytral apex is more broadly rounded, the declivital punctures are strongly impressed, and the male frons is sparsely, minutely punctured below and shining. Intergradation between the two forms could not be demonstrated from the limited material at hand.

## 17. Scolytodes unipunctatus (Blandford)

Hexacolus unipunctatus Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):182 (Lectotype, female; Cubilguitz, Alta Verapaz, Guatemala; British Mus. Nat. Hist., present designation)
Diagnosis. - The point of insertion of the antennae, the odd frontal elevation of the female, and the constricted, depressed declivital interstriae 2 are all unique in this genus. The over-all surface sculpture is also unmatched in this genus.
Female.- Length $1.75-1.85 \mathrm{~mm}, 2.5$ times as long as wide; color black.

Frons very weakly, broadly concave from epistoma to upper level of eyes; median fourth of lower third occupied by a large, black, subpyriform, abruptly elevated process increasing in height dorsally, its upper limit projecting slightly; surface of concavity on lower half yellow, evidently somewhat spongy, becoming minutely granulate-punctate above; vestiture of uniformly distributed, very fine, moderately abundant, rather long hair. Antennal insertion immediately above middle of distance from epistomal margin to upper level of eyes; scape with a small tuft of hair near apex.

Pronotum 1.1 times as long as wide; widest near base, sides almost straight, converging very slightly on basal two-thirds, rather broadly rounded in front; anterior fifth slightly more declivous and very feebly asperate; surface subreticulate, with a bright sheen, punctures moderately large near base, small anteriorly, very shallow, continuing to anterior margin. Glabrous.

Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal half, rather narrowly rounded behind; striae 1 impressed, others feebly impressed toward declivity, punctures moderately coarse, rather deep; interstriae three times as wide as striae, very smooth, brightly shining, punctures uniseriate, very fine, shallow. Declivity rather gradual, convex; striae impressed, punctures small, shallow; interstriae 2 rather strongly narrowed, impressed, 1,3 , and 9 convex, slightly elevated. Glabrous.

Male.-Similar to female except frons convex, smooth, with an opalescent sheen, finely, sparsely punctured; scape without tuft of hair; punctures on pronotum not reduced in size anteriorly.

Distribution.- Guatemala.
guatemala: Cubilguitz, Alta Verapaz, G. C. Champion.

Notes.- The above treatment was based on six syntypes. The first female syntype bears a type label but has never been officially designated as such. I here designate that female syntype, from Cubilguitz, as the lectotype of Hexacolus unipunctatus Blandford.

## 18. Scolytodes cecropii (Schedl)

Hexacolus cecropii Schedl, 1937, Arb. Morph. Taxon. Ent. Berlin-Dahlem 4:66 (Holotype, female; La Hondura, Costa Rica; Schedl Coll.)
Diagnosis.- This species is very closely related to blandfordi (Schedl). Because females of blandfordi are unknown, it can be stated only that the two known males are distinguished from cecropii males only by slight differences in punctation of the elytral declivity as noted in the above key. More material could very well indicate the existence of only one species.

Female.- Length $1.7-2.0 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to black.

Frons flattened on a somewhat narrow area from upper level of eyes to epistoma; lower three-fifths with a pair of subcontiguous, almost parallel, median, shining, longitudinal carinae, diverging very slightly toward epistoma; surface reticulate, largely obscured by a dense brush of long, yellow hair arising from margins of upper third to well above eyes, tips of longest hair reaching epistomal margin.

Pronotum 1.0 times as long as wide; widest at base, sides feebly arcuate, converging slightly, rather broadly rounded in front; surface finely reticulate, dull, punctures fine, shallow, rather widely spaced, attaining anterior margin, asperities entirely absent. Glabrous.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on slightly less than basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures small, shallow, scarcely evident; interstriae about three times as wide as striae, obscurely wrinkled, subshining, punctures obscure, very shallow. Declivity convex, moderately steep; punctures small, shallow, obscure. Glabrous.

Male. - Similar to female except frons weakly convex above, a slight transverse impression just above epistoma, glabrous.

Distribution.- Costa Rica.
COSTA RICA: Tapantí, Cartago, 24-X-63, 1300 m , No. 267, Cecropia peltata, S. L. Wood. The type series was labeled "La Palma, 1450 m , La Hondura, Costa Rica, F. Nevermann, 5-VI-36, Cecropia mexicana." It is presumed this locality is in the La Palma area between Volcán Barba and Volcán Irazu in San José Province, because Nevermann lived nearby in a suburb of San José.

Biology.- Five specimens of this species were taken as they walked on or were beginning entrance tunnels in a fallen Cecropia leaf petiole. None of the entrance tunnels indicated the location of brood chambers.

Notes.- The above treatment was based on a male paratype, on two male and two female topotypic homotypes, on 28 other topotypes bearing identical data to the type, and on 5 other specimens.

## 19. Scolytodes blandfordi (Schedl)

Hexacolus blandfordi Schedl, 1936, Arch. Inst. Biol. Veg. Río de Janeiro 3:104 (Holotype, male; Hamburgfarm on Río Reventazón, Limón, Costa Rica: Schedl Coll.)
Diagnosis.- This species is doubtfully distinct from cecropii (Schedl).

Male.- Length $1.4-1.5 \mathrm{~mm}, 2.4$ times as long as wide; color dark reddish brown.

As in cecropii except frons more coarsely reticulate, transverse impression above epistoma lacking a feeble median elevation; punctures on elytral declivity very slightly larger, deeper.

Distribution.- Costa Rica.
COSTA RICA: Hamburgfarm on Río Reventazón, Limón, F. Nevermann; Pandora, Limón, 23-VIII-63, 50 m, No. I46, Cecropia petiole, S. L. Wood.

Biology.- One male was taken from a new tunnel in a Cecropia leaf petiole.

Notes.- The above treatment was based on a male that was compared directly to the unique holotype by me.

## 20. Scolytodes venustus Wood

Scolytodes venustus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):18 (Holotype, female; Rodeo, Esquintla, Guatemala; Wood Coll.)
Diagnosis.- This species is distinguished from pseudopiceus Wood by the more finely punctured female frons, with the pubescence more abundant and evenly distributed, and by the striae, which are not impressed, their punctures are fine and shallow.

Female.- Length $1.4-1.8 \mathrm{~mm}, 2.3$ times as long as wide; color very dark brown, almost black.

Frons flattened from upper level of eyes to epistoma (rather narrowly above); surface subreticulate and finely punctured above eyes, subshining and rather coarsely punctured on flattened area, a small, shining,
impunctate, central area on lower half; epistomal lobe not evident; vestiture consisting of fine, sparse, moderately long hair.

Pronotum 1:0 times as long as wide; widest at base, sides of basal half almost straight and parallel, rather broadly rounded in front; entire surface reticulate, punctures coarse, deep, rather close, becoming somewhat smaller in anterior area; not at all asperate anteriorly. Glabrous except at sides.

Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae 1 rather strongly, others rather weakly impressed, punctures moderately large, deep, very close; interstriae about one and one-half times as wide as striae, almost smooth, with a few fine points, punctures more than half as large as those of striae, deep, rather close, uniseriate. Declivity steep, convex, about as on disc, except all punctures smaller. Glabrous, except for sparse, short hair on sides and marginal areas behind.

Male. - Similar to female except frons convex, reticulate, finely, sparsely punctured, subglabrous; anterior fourth of pronotum finely asperate, punctures in this area obscured.

Distribution.- Guatemala to Costa Rica.
GUatemala: Rodeo, Esquintla, 4-VI-64, 200 mn , No. 20, Plumeria and No. 678, Fieus, No. 677, S. L. Wood. COSTA RICA: Playa del Coco, Guanacaste, II-VII-66, I m, No. 20, Plumeria rubra. S. L. Wood.

Host.- Plumeria rubra, P. sp., Ficus sp.
Biology.- This species was taken from the same branches as plumeriae and evidently has similar habits. Mature, fully colored brood was found 20 days after one branch was cut.

Notes.- The above treatment was based on the type series of 82 specimens.

## 21. Scolytodes striatus (Eggers)

Hexacolus striatus Eggers, 1934, Ent. Blätt. 30:79 (Holotype, male; Turrialba. Costa Rica; U.S. Nat. Mus.)
Diagnosis.- This species is distinguished from venustus Wood by the slightly stouter form, by the total absence of asperities on the pronotum, by the slightly larger strial punctures and the more strongly convex interstriae on the declivity, and by the different elytral vestiture.

Male.- Length $1.7 \mathrm{~mm}, 2.0$ times as long as wide; color very dark brown.

As in male venustus except differing as indicated above. Elytral vestiture, particularly on declivity, of stout, erect, short, rather abundant setae; each seta slightly longer than distance equal to diameter of a strial puncture.

Distribution.- Costa Rica.
COSTA RICA: Turrialba.
Notes.- The above treatment was based on the holotype.

## 22. Scolytodes pseudopiceus Wood

Scolytode's pseudopiceus W'ood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. IO(2):I8 (Holotype, female; San Isidro del General, San José, Costa Rica; Wood Coll.)
Diagnosis. - This species is closely related to venustus Wood, but it is distinguished by characters summarized in the above diagnosis and key.

Female.- Length $1.4-1.9 \mathrm{~mm}, 2.1$ times as long as wide; color very dark brown, almost black.

Frons flattened from just above upper level of eyes to epistoma, evidently feebly convex near center; rather coarsely, closely punctured; ornamented by a rather scanty brush of fine, long hair, distribution about uniform, except reduced or absent toward center.

Pronotum 1.04 times as long as wide; widest near base, sides weakly arcuate, converging slightly to anterior third, then rather narrowly rounded in front; summit indefinite, near middle; anterior third appearing weakly crenulate from above, but only feebly wrinkled from other aspects; surface subreticulate, rather coarsely, deeply, closely punctured from base to anterior margin. Glabrous.

Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures rather fine, deep; interstriae more than twice as wide as striae, almost smooth, punctures subequal to those of striae, in almost regular, uniseriate rows. Declivity steep, convex; striae 1 slightly impressed; all punctures smaller than on disc. Glabrous.

Male.- Similar to female except frons convex, with a slight transverse impression
just above epistomal margin, surface reticulate and sparsely, rather deeply punctured.

Distribution.- Costa Rica.
costa rica: San Isidro del General, San José, 5-XII-63, 1000 m , No. 278, Ficus sp., S. L. Wood.

Biology.- Small, unthrifty twigs in living trees are selected for attack. The habits apparently are similar to most other species in the genus.

Notes. - The above treatment was based on the type series of 19 specimens.

## 23. Scolytodes setosus (Blandford)

Hexacolus setosus Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):181 (Holotype, female?; Cerro Zunil, Guatemala; British Mus. Nat. Hist.)
Diagnosis.- This species evidently is intermediate in its relationships between hirsutus Wood and crassus Wood, but it is distinguished by the elytral vestiture and by other characters mentioned in the above key.

Female.- Length 1.6 mm , about 2.1 times as long as wide; color brown, anterior half of pronotum darker.

Frons broadly convex, a slight transverse impression on lower third; surface smooth, rather coarsely, sparsely, deeply punctured; vestiture of sparse, fine, long, uniformly distributed hair.

Pronotum 0.94 times as long as wide; widest on basal half, sides very weakly arcuate on posterior two-thirds, then converging rather abruptly to broadly rounded anterior margin; surface weakly reticulate, punctures moderately fine, spaced within a row by one to two diameters of a puncture, moderately deep, smaller and less strongly impressed on anteromedian area. Vestiture rather abundant, of fine, long hair.

Elytra about 1.4 times as long as wide (slightly spread on type); outline as in allied species; striae not impressed, punctures moderately fine, rather deep, close; interstriae two to three times as wide as striae, smooth, shining, punctures very fine, deep, moderately confused on 1 and 2, uniseriate on 3-9. Declivity convex, rather steep; sculpture about as on disc. Vestiture consisting of rows of fine, moderately long, semirecumbent strial hair; interstrial setae of two types, some similar to strial setae and alternating in rows with bristles, others form rows of erect bristles each as long as distance between
rows, slightly closer to one another within a row, their tips blunt, slightly flattened.

Distribution.- Guatemala.
GUATEMALA: Cerro Zunil, $4000 \mathrm{ft}(1300 \mathrm{~m}$ ), G. C. Champion.

Notes.- The above treatment was based on the holotype.

## 24. Scolytodes punctiferus Wood

Scolytodes punctifer Wood, 1971, (nee. Wood 1969) Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3): 15 (Holotype, male; Volcán Irazu, Cartago, Costa Rica; Wood Coll.)
Scolytodes punctiferus Wood, 1976, Great Basin Nat. 36:348. Replacement name
Diagnosis.- This pubescent species is distinguished from punctatus Eggers by the much smaller strial punctures, with the interstrial punctures much smaller than those of the striae, by the smooth pronotal surface, with smaller punctures, and by the more abundant elytral hair.

Male.- Length $1.5 \mathrm{~mm}, 2.0$ times as long as wide; color very dark brown, elytra slightly lighter, abundant vestiture pale.

Frons convex, a slight transverse impression just above epistoma; surface obscurely reticulate, punctures rather small, deep, moderately close; vestiture fine, sparse, short. Sutures of antennal club almost obsolete.

Pronotum 0.95 times as long as wide; sides parallel, feebly arcuate on basal half, broadly rounded in front; surface obscurely reticulate behind, distinctly reticulate toward anterior margin, punctures coarse, deep, close. Vestiture fine, abundant, moderately long.

Elytra 1.3 times as long as wide; sides almost straight and parallel on basal twothirds; striae 1 feebly, others not impressed, punctures rather coarse, deep; interstriae smooth, about one and one-half times as wide as striae, punctures rather large, uniseriate except slightly confused on 2 . Declivity convex, rather steep; all punctures distinctly smaller, otherwise similar to disc. Vestiture of rather abundant, fine, erect, strial and interstrial hair, and slightly longer, uniseriate rows of slightly coarser, interstrial hair; each long hair about one and one-half times as long as distance between rows.

Distribution.- Costa Rica.
COSTA RICA: Volcán Irazu, Cartago, 26-IX-63, 2300 m , No. 207, Oreopanax nubigenus, S. L. Wood.

Biology.- One male specimen was taken from a twig of a broken limb.

Notes.- The above treatment was based on the holotype.

## 25. Scolytodes hirsutus Wood

Scolytodes hirsutus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3): 16 (Holotype, male; Tapantí, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from punctiferus Wood by the fine, confused, elytral punctures, by the strongly reticulate, dull pronotal surface, and by the much finer pronotal punctures.

Male.- Length $1.7 \mathrm{~mm}, 2.1$ times as long as wide; color black.

Frons moderately convex, surface strongly reticulate, punctures fine, deep, moderately abundant; vestitúre inconspicuous.

Pronotum 0.95 times as long as wide; outline as in punctiferus; surface strongly reticulate, dull, punctures fine, rather shallow, moderately abundant. Vestiture fine, rather abundant, moderately long.

Elytra 1.2 times as long as wide; outline as in punctiferus; strial and interstrial punctures equal in size, small, rather shallow, interstrial punctures confused, those of striae distinguished with difficulty. Declivity convex, rather steep; punctures minute, confused. Vestiture of fine, long strial and interstrial hair, and slightly longer uniseriate rows of interstrial hair; each longer hair slightly longer than distance between rows.

Distribution.- Costa Rica.
COSTA RICA: Tapantí, Cartago, 2-VII-63, 2300 m , No. 8, S. L. Wood.

Biology.- The holotype was removed from an old section of cut vine (somewhat similar to Clematis) that was completely riddled by this species.

Notes.- The above treatment was based on the holotype.

## 26. Scolytodes crassus Wood

Scolytodes crassus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. I5(3):16 (Holotype, male; Barro Colorado 1sland, Canal Zone, Panama; Wood Coll.)
Diagnosis.- The position of this small, stout species is problematical, but the rows of very fine strial and interstrial hair suggest a possible relationship to hirsutus Wood.

Male.- Length $1.0 \mathrm{~mm}, 1.9$ times as long as wide; color yellowish brown, apparently not fully colored.

Frons convex, surface obscurely reticulate, shining, punctures rather large, deep, not close; fine, moderately abundant toward epistoma.

Pronotum 0.94 times as long as wide; widest at base, sides indistinctly arcuate, converging very slightly on basal two-thirds, rather narrowly rounded in front; surface smooth and shining, punctures small, rather shallow, moderately close, irregularly spaced. Vestiture of short, very fine, moderately abundant, recumbent hair.

Elytra 1.2 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae feebly if at all impressed, punctures large, moderately deep, close; interstriae almost as wide as striae, smooth, shining, punctures very fine, uniseriate, close. Declivity convex, rather steep; strial punctures gradually reduced to about two-thirds size on disc; interstriae slightly wider than striae, very feebly convex. Vestiture consisting of uniseriate rows of very fine, recumbent, moderately long strial and interstrial hair; in addition, odd-numbered interstriae on posterior half of elytra bear widely spaced, erect, spatulate bristles of moderate length, about six such bristles on each interstriae.
Distribution.- Panama.
PANAMA: Barro Colorado Island, Canal Zone, XI-52 to III-53, J. Zetek.

Biology.- Unknown. The type evidently was taken at light.

Notes.- The above treatment was based on the unique holotype.

## 27. Scolytodes venustulus Wood

Scolytodes venustulus Wood, 1967, Great Basin Nat. 27:124 (Holotype, male; Cerro Punta, Chiriquí, Panama, Wood Coll.)
Diagnosis. - This species appears to be closely related to venustus Wood, but it is distinguished by the smaller size, by the reticulate, less closely punctured posterior area of the pronotum, by the unimpressed elytral striae, and by the almost equal size of strial and interstrial punctures.

Male.- Length 1.3-1.5 mm, 2.3 times as long as wide; color dark brown, with a slight reddish cast.

Frons convex, with a transverse impression just above epistoma; surface smooth and shining to a level above eyes, punctures very fine; vestiture fine, hairlike, largely confined to epistomal area.

Pronotum 1.0 times as long as wide; widest just behind middle, sides rather weakly arcuate on basal two-thirds, rather narrowly rounded in front; dorsal profile arched from base, a little more strongly declivous on anterior fourth; surface reticulate, with rather coarse, deep, moderately close punctures on basal two-thirds, finely, closely asperate in median area in front, punctures reaching anterior margin in lateral areas; punctures on dise separated by distances about equal to their own diameters. Glabrous.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, rather narrowly rounded behind; base of suture just behind scutellum acutely but not strongly elevated; striae not impressed, punctures moderately large, deep; interstriae slightly wider than striae, smooth and shining, punctures fine, distinct. Declivity convex, rather steep; strial punctures reduced; interstriae 2 narrow, not wider than diameter of a strial puncture (noticeably wider on one paratype). Vestiture consisting of minute strial and interstrial hair, and longer, erect bristles on declivital interstriae $1,3,5$, and 7 . Interstriae 10 ending before level of hind coxa.

Distribution. - Panama.
Panama: Cerro Punta, Chiriquí, Il-1-64, 1800 m . No. 407, S. L. Wood.

Host.- Oreopanax probably xalapense.
Biology.- This species infested the phloem tissues of cut seedlings of its host about 5 cm in diameter.

Notes.- The above treatment was based on the type series of five specimens.

## 28. Scolytodes clusiae Wood

Scolytodes clusiae Wood, 1969. Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):14 (Holotype, female; Volcán Poas, Heredia, Costa Rica; Wood Coll.)
Diagnosis.- Evidently not closely related to previously known species. It has interstriae

10 ending before level of metacoxae, the protibiae armed by a small tooth on posterior face just before the tarsal insertion and between the terminal mucro and first or second marginal tooth; the female frons is broadly, shallowly concave.

Female.- Length $1.7-1.9 \mathrm{~mm}, 2.4$ times as long as wide; color black.

Frons broadly, shallowly concave from upper level of eyes to level of antennal insertion; surface closely, deeply, somewhat coarsely punctured over entire frontal area in and out of concavity; median epistomal lobe conspicuous, broad, short, continuous with surface of frons; vestiture very fine, not abundant, longer above, not evident along epistoma.

Pronotum 1.0 times as long as wide; widest at base, very slightly constricted one-third pronotum length from base, weakly arcuate on anterior half, then broadly rounded in front; surface reticulate, with fine, obscure, rather widely spaced punctures on posterior half, equally fine, sparse, minute granules on anterior third. Almost glabrous.

Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; widest one-third from base, sides feebly arcuate, abruptly rounded at declivital base, narrowly rounded behind; striae not impressed, punctures very small, not deep; interstriae about twice as wide as striae, shining, irregular due to obscure surface lines, punctures not evident. Declivity convex, rather steep; striae 1 weakly impressed above, punctures on all striae obscurely indicated. Vestiture consisting of a few rather short hairs and, on lower half, more numerous, very short, semirecumbent hair.

Male. - Similar to female except frons rather strongly convex, finely, obscurely punctured, surface reticulate, vestiture sparse, short, inconspicuous; strial punctures rather obscure.

Distribution.- Costa Rica.
COSTA RICA: Volcán Poas, Heredia, 19-VIII-66, 2600 m, No. 96, Clusia, S. L. Wood.

Biology.- This species infests the phloem and outer bark in unthrifty twigs of living Clusia trees.

Notes.- The above treatment was based on the type series of 18 specimens.

## 29. Scolytodes radiatus Wood

Scolytodes radiatus Wood, 1977, Great Basin Nat. 37:218 (Holotype, female; La Georgiana, 79 km SE San José, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from clusiae Wood and volcanus Wood by the slightly larger size, by the much coarser pronotal punctures, and by the very different female frons.

Female.- Length $1.6-1.9 \mathrm{~mm}, 2.4$ times as long as wide; color almost black.

Frons convex and virtually glabrous as in males of allied species.

Pronotum much as in volcanus except punctures much larger, each equal to from half to full diameter of a strial puncture (variable).

Elytra about as in amabilis Wood except punctures larger and vestiture less abundant; striae not impressed, punctures rather coarse, deep; interstriae slightly wider than striae, smooth, shining, punctures uniseriate, less than half diameter of those of striae. Subglabrous, a few fine setae on odd-numbered interstriae on posterior half.
Male.-Similar to female in all respects.
Distribution.- Costa Rica.
COSTA RICA: La Georgiana, 79 km SE San José, $31-$ VII-65, Quercus, L. S. Otvos.

Notes.- The above treatment was based on the type series of 15 specimens.

## 30. Scolytodes clusiacolens Wood

Scolytodes clusiacolens Wood, 1967, Great Basin Nat. 27:121 (Holotype, female; 10 km E Volcán Parícutin, Michoacán, Mexico; Wood Coll.)
Diagnosis.- This species is more closely allied to clusiae Wood than to other known species, but it may be distinguished by the larger size, by the coarsely, deeply punctured pronotum and elytra and, in the female, by the weakly convex frons.

Female.- Length $1.8-2.9 \mathrm{~mm}, 2.5$ times as long as wide; color black.

Frons planoconvex from a point well below upper level of eyes to epistoma, convex above that point, transition rather abrupt; surface reticulate, finely, deeply, rather closely punctured; vestiture inconspicuous, consisting of very fine, moderately abundant, uniformly distributed hair.

Pronotum 1.1 times as long as wide; sides almost straight or very feebly constricted on
basal two-thirds, broadly rounded in front; dorsal profile weakly arched from base, more strongly declivous on anterior fifth; surface reticulate, with rather coarse deep punctures from base to near anterior margin, gradually replaced by smaller punctures laterally and minute asperities medially on anterior fifth. Glabrous except near lateral and anterior margins.

Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae impressed, punctures rather large, deep; interstriae slightly narrower than striae, convex, shining, punctures fine, sharply but not deeply impressed, uniseriate, some of them slightly subgranulate on anterior margins (variable in series). Declivity convex, rather steep; striae 1 only distinctly impressed, punctures distinctly smaller than on disc; interstrial punctures minute, clearly impressed. Vestiture fine, hairlike in regular strial and interstrial rows on teneral specimens.

Male.-Similar to female except frons convex to transverse impression just above epistoma, punctures larger, deeper, vestiture almost confined to epistomal area; more nearly subgranulate interstrial punctures.

Distribution.- Michoacán to Honduras.
MEXICO: Michoacán: 10 km E Volcán Parícutin, 19-V1-65, 2500 m , No. 85, Clusia, S. L. Wood. Chiapas: 32 km N Bochil, 10-VI-69, D. E. Bright. GUATEMALA: Volcán Pacaya, 1-V1-64, 1300 m, No. 659, Clusia, S. L. Wood. HONDURAS: Cerro Peña Blanca, F. Morazán, 23-V-64, 2000 m, No. 530, Clusia, S. L. Wood.

Host.- Clusia sp.
Biology.- This species infested phloem tissues in unthrifty twigs and branches of its living host.

Notes.- The above treatment was based on the type series of 83 specimens.

## 31. Scolytodes clusiavorus Wood

Scolytodes clusiavorus Wood, 1967, Great Basin Nat. 27:122 (Holotype, female; Volcán de Agua, Esquintla, Guatemala; Wood Coll.)
Diagnosis.- This species is distinguished from clusiae Wood by the smaller size, by the more sharply, somewhat more deeply punctured pronotum and elytra, particularly the elytral declivity, and, in the female, by the less deeply, less extensively concave frons.

Female.- Length $1.3-1.6 \mathrm{~mm}, 2.6$ times as long as wide; color black.

Frons shallowly, broadly planoconcave from just below upper level of eyes to epistoma; surface subshining, closely, finely, deeply, uniformly punctured from vertex to epistoma; vestiture consisting of rather coarse, moderately long, uniformly but rather sparsely distributed hair.

Pronotum 1.1 times as long as wide; sides almost straight or very feebly constricted on posterior two-thirds, broadly rounded in front; surface reticulate, punctures rather fine, deep, moderately close; anterior fifth more strongly declivous, with a few minute asperities in median area, punctures attaining anterior margin only in lateral areas. Vestiture confined to anterior and lateral areas.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, narrowly rounded behind; striae not impressed, punctures moderately large, deep; interstriae slightly narrower than striae, almost smooth, with some irregular lines, punctures minute, almost uniseriate, not at all granulate. Declivity convex, rather steep; strial punctures smaller and shallower than on disc. Vestiture consisting of rows of minute strial hair and longer, erect rows of coarser interstrial hair.

Male. - Similar to female except frons strongly convex, reticulate, punctures rather coarse, sparse, vestiture restricted to epistomal margin.

Distribution.- Guatemala.
MEXICO: Veracruz: Matías Romero, 29-VI-67, Clusia, S. L. Wood. GUATEMALA: Volcán de Agua, Esquintla, 19-V-64, 1000 m , No. 593, Clusia, S. L. Wood.

Biology. - This species infests phloem tissues of unthrifty twigs and branches of its living host.

Notes.- The above treatment was based on the type series of five specimens.

## 32. Scolytodes amabilis Wood

Scolytodes amahilis Wood. 1975. Great Basin Nat. 35:26 (Holotype, female; Mt. Tzontehuitz, Chiapas, Mexico; Canadian Nat. Coll.)
Diagnosis. - In general body features, this species is very similar to clusiavorus Wood, but the female frons is much more similar to volcanus Wood. It is distinguished from those species as indicated below.

Female.- Length 1.4-1.6 mm, 2.5 times as long as wide; color very dark brown, almost black.

Frons essentially convex, with a very shallow, subconcave area on median third just below upper level of eyes, this impression continued on median fifth as an abrupt, shallow sulcus to epistoma, median half of lateral areas bordering sulcus with numerous beadlike granules, remaining areas somewhat dull, with fine punctures; surface of sulcus shining, almost smooth; rather sparse vestiture limited to margins, of fine, long hair, those on dorsal margin attaining level of antennal insertion, shorter laterally and below.

Pronotum and elytral outlines as in clusiacolens Wood; pronotum surface reticulate, punctures as in clusiavorus; strial and interstrial punctures similar to but slightly larger than in clusiavorus. Strial setae almost obsolete; interstrial setae almost obsolete on evennumbered interstriae, fine, rather short, and widely spaced on odd-numbered interstriae.

Male. - Similar to female except frons convex, reticulate, vestiture very sparse, short, inconspicuous.

Distribution.- Chiapas.
MEXICO: Chiapas: Mt. Tzontehuitz, 29-V-69, 3000 m, 23-VI-69, Quercus, D. E. Bright.

Notes.- The above treatment was based on the type series of 38 specimens.

## 33. Scolytodes canalis Wood

Scolytodes canalis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):13 (Holotype, female; Mt. Tzontehuitz, Chiapas, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from the allied parvulus Wood by the slightly protuberant, lower female frons, which has a narrow, shallow, median sulcus, with frontal vestiture confined to the upper margins; the discal interstrial punctures are obsolete; and the pronotal and strial punctures are moderately course.

Female.- Length $1.4-1.7 \mathrm{~mm}, 2.5$ times as long as wide; color black.

Frons rather broadly convex, slightly protuberant on lower half, median fourth just below upper level of eyes shallowly concave, impression continued on median sixth as a shallow sulcus to epistoma; surface of upper half almost smooth, rather finely, deeply
punctured, becoming finely granulate on lower half except reticulate in impressed area; vestiture apparently restricted to margins of upper half, tips of some long, yellow, hairlike setae arising on vertex reaching to epistoma.

Pronotum 1.1 times as long as wide; sides almost straight on more than basal twothirds, converging slightly to anterolateral angles, broadly rounded in front; anterior third weakly declivous; surface reticulate, subshining, punctures on posterior half moderately coarse, deep, not close, decreasing in size on anterior half, most of them replaced by minute granules on anterior sixth or obsolete. Glabrous.

Elytra 1.6 times as long as wide; sides straight on basal two-thirds, very slightly wider at base of declivity, rather narrowly rounded behind; striae not impressed, punctures moderately deep; interstriae as wide as striae, smooth, shining, punctures obsolete, some with one to three minute granules. Declivity steep, convex; strial punctures smaller than on dise; a few minute interstrial punctures usually present. Vestiture of fine sparse, erect, interstrial hair of moderate length on odd-numbered interstriae, much shorter to obsolete on even-numbered interstriae.

Male.- Similar to female except frons evenly, more strongly convex, surface reticulate, with scattered punctures, subglabrous.

Distribution.- Chiapas.
MEXICO: Chiapas: Mt. Tzontehuitz, 26, 29-V-69, I2-VI-69, 3100 m , D. E. Bright.

Notes.- The above treatment was based on the type series of 22 specimens.

## 34. Scolytodes volcanus Wood

Scolytodes volcanus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):I4 (Holotype, female; Volcán Poas, Heredia, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from clusiae Wood by the smaller size, by the small tooth on the posterior face of the protibiae, by the larger strial punctures, and by the female frons being more narrowly impressed to the vertex.

Female.- Length $1.2-1.4 \mathrm{~mm}, 2.3$ times as long as wide; color very dark brown, almost black.

Frons narrowly, shallowly concave from epistomal margin to above upper level of
eyes; surface finely, shallowly but distinctly, densely punctate, epistomal lobe mostly shining; vestiture largely confined to margin of impressed area, fine, short below, somewhat longer above, moderately abundant, minute in concavity.

Pronotum 1.1 times as long as wide; sides almost straight and parallel on basal half, then somewhat arcuate and rather narrowly rounded in front; surface reticulate, punctures fine, sparse, rather obscure, devoid of granules. Glabrous.
Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, narrowly rounded behind; striae not impressed, punctures moderately large, deep; interstriae slightly wider than striae, shining, with very few impressed lines, punctures obscure, mostly obliterated. Declivity rather steep, convex; an occasional deep interstrial puncture present; shining. Glabrous.

Male.- Similar to female except frons convex, reticulate, obscurely punctured, vestiture greatly reduced, inconspicuous; a few interstrial punctures clearly impressed.
Distribution.- Costa Rica.
COSTA RICA: Volcán Poas, Heredia, I4-VII-63, 2900 m, Nos. 44, 48, S. L. Wood.

Biology. - This species was collected from the phloem tissues of a recently cut woody vine (liana) and from cut tree seedlings.

Notes.- The above treatment was based on the type series of 26 specimens.

## 35. Scolytodes irazuensis Wood

Scolytodes irazuensis Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):15 (Holotype, female; Volcán Irazu, Cartago, Costa Rica; Wood Coll.)
Diagnosis. - Rather closely related to parvulus Wood but larger, the female frons only shallowly impressed with setae on vertex extending half the distance to the antennal insertion, and the general sculpture coarser.

Female.- Length $1.5-1.9 \mathrm{~mm}, 2.4$ times as long as wide; color very dark brown.

Frons rather broadly, longitudinally impressed from upper level of eyes to epistoma; lateral margins above level of antennal insertion subcarinately elevated almost to upper level of eyes; surface finely, closely, deeply punctured; vestiture mostly confined to vertex, rather long, moderately abundant
(largely abraded in type), none of setae long enough to reach half distance to level of antennal insertion; only a few setae arise below upper level of eyes.

Pronotum 1.0 times as long as wide; sides weakly arcuate and converging slightly on basal two-thirds, rather broadly rounded in front; surface reticulate, rather coarsely, shallowly, not closely punctured, punctures intermixed with very minute asperities on rather strongly declivous anterior fourth. Glabrous.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures small, not sharply defined; interstriae almost twice as wide as striae, punctures small, deep, almost uniseriate. Declivity convex, steep; strial and interstrial punctures smaller than on disc, rather deep. Vestiture consisting of less than a dozen widely scattered, erect, hairlike bristles on disc and declivity, mostly on interstriae 3.

Male.-Similar to female except frons convex with a slight impression above epistoma, obscurely reticulate, indistinctly punctured; strial and interstrial punctures much less clearly defined on disc and declivity.

Distribution. - Costa Rica.
COSTA RICA: Volcán Irazu, Cartago, 26-IX-63, 2300 m, No. 207, Oreopanax nuligenus, and 28-VI-63, 2800 m, No. 4 Oreopanax xalapense, and 13-VIl-63, No. 41. S. L. Wood.

Hosts.- Oreopanax nubigenus and $O$. xalapense.

Biology.- This species infests phloem tissues in unthrifty and cut or damaged branches and boles of at least four host species. The egg cavity has the long axis transverse. There were several niches resembling over-sized egg niches in which groups of eggs were loosely packed. An occasional beetle bored through the wood to the pith in the smaller branches.

Notes. - The above treatment was based on the type series of 101 specimens.

## 36. Scolytodes parvulus Wood

Scolytodes parculus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. IO(2): 14 (Holotype, female; Pandora, Limón, Costa Rica: Wood Coll.)
Diagnosis.-Similar to volcanus Wood but smaller, the female frons is armed by a
pair of longitudinal carinae, the strial punctures are reduced in size, and the female frontal vestiture is uniformly distributed.

Female.- Length 0.9-1.1 mm, 2.3 times as long as wide; color rather dark brown.

Frons flattened from upper level of eyes to epistoma; median half of each side just inside of lateral margin armed by a shining longitudinal carina; this pair of carina beginning at level of antennal insertion and ending before upper level of eyes; surface finely, rather closely punctured in impressed and lateral areas, reticulate above eyes; vestiture fine, moderately long around margin, somewhat shorter in central area, moderately abundant.

Pronotum 1.0 times as long as wide; sides very weakly arcuate and feebly converging anteriorly on basal two-thirds, broadly rounded in front; surface reticulate, with sparse, minute punctures extending from base to anterior margin. Glabrous.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal half, rather narrowly rounded behind; striae 1 weakly impressed, others not at all impressed, punctures fine, shallow, rather obscure; interstriae wider than striae, not entirely smooth, punctures sparse, fine, obscure. Declivity convex, steep; essentially as on disc but interstriae narrower and punctures smaller, features not sharply defined. Vestiture consisting of less than a dozen moderately long, erect interstrial bristles.

Male. - Similar to female except frons convex, with a slight transverse impression just above epistoma, surface obscurely reticulate, shining, sparsely punctured, vestiture very sparse, mostly near epistoma; pronotum obscurely reticulate, subshining.

Distribution.- Veracruz to Costa Rica.
MEXICO: Veracruz: Lago Catemaco, 16-20-VI-69, D. E. Bright: 16 km NW Sontecomepan, 18-VI-69, D. E. Bright. Chiapas: 8 km SW El Bosque, 3-VIl-69, D. E. Bright: Palenque Ruins, 9-V-69, D. E. Bright. COSTA RICA: Pandora, Limón, 23-VIII-63, $50 \mathrm{~m}, \mathrm{No} .146, C e-$ cropia, S. L. Wood.

Host.-Cecropia sp.
Biology.- This species infests the petioles of fallen Cecropia leaves.

Notes.- The above treatment was based on the type series of 14 specimens and on 91 other specimens.

## 37. Scolytodes acares Wood

Scolytodes acares Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):15 (Holotype, female; Río Damitas, Dota Mts., San José, Costa Rica; Wood Coll.)
Diagnosis.- Allied to parvulus Wood, but the female frontal vestiture is longer and much more abundant near the vertex, and the pronotal punctures are more coarsely, deeply impressed in the posterior area.

Female.- Length 0.9-1.1 mm, 2.4 times as long as wide; color dark brown.

Frons narrowly flattened from well above upper level of eyes to epistoma, margined at sides by a pair of shining, longitudinal carinae extending almost from epistoma (halfway between level of antennal insertion and epistomal margin) to near upper level of eyes; surface sculpture obscure between carinae, evidently smooth and finely punctured; vestiture largely confined to vertex, above upper level of eyes, consisting of a dense, long brush of subplumose, yellow hair, its tips extend to a point below level of antennal bases.

Pronotum and elytra as in parvulus except pronotum more narrowly rounded in front and its punctures somewhat larger.

Male. - Similar to female except frons convex, with a slight transverse impression just above epistoma, surface reticulate, sparsely punctured, vestiture reduced to a few setae near epistoma.

Distribution.- Guatemala to Panama.
GUATEMALA: Palin, Esquintla, 19-V-64, 350 m , No. 585. COSTA RICA: Rio Damitas, Dota Mts., San José, 22-VII-63, 250 m , No. I30; Rincón de Osa, Puntarenas, II-VIII-66, 30 m , No. 58. PANAMA: Barro Colorado Island, 27-XII-63, 70 m , No. 339. All were collected by me from the same host.

Host.-Cecropia sp.
Brology. - This species infests the petioles of recently fallen Cecropia leaves. A somewhat transverse egg chamber is formed immediately under the thin outer bark; larval mines follow the grooves between the longitudinal fibers.

Notes.- The above treatment was based on the type series of 44 specimens.

## 38. Scolytodes ochromae Wood

[^8]Diagnosis.- This species is distinguished from swieteniae (Blackman), by interstriae 10 not extending behind the level of the metacoxae, by the interstriae being almost devoid of punctures, and by the absence of a frontal carina.

Female.- Length 1.3-1.5 mm, 2.1 times as long as wide; color rather dark brown.

Frons almost flattened above to upper level of eyes, shallowly concave below, epistoma somewhat elevated; central area on upper half smooth, impunctate, remaining areas coarsely, densely, deeply punctured; lateral area above level of antennal insertion ornamented by a scanty tuft of long, yellow hair, a few scattered setae on lower third.

Pronotum 0.95 times as long as wide; widest at base, sides feebly arcuate and slightly converging anteriorly on basal twothirds, then rather abruptly converging toward very narrowly anterior margin; summit indefinite, near middle; anterior three-fourths armed by broad, rather coarse crenulations; basal fourth subreticulate, shining. Glabrous.

Elytra 1.3 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal half, obtusely angulate behind; striae 1 weakly, others not at all impressed, punctures rather coarse, shallow, rows not entirely straight; interstriae almost twice as wide as striae, almost smooth, punctures not evident. Declivity steep, convex; strial punctures evidently smaller than on disc; occasional interstrial punctures obscurely indicated; apex turned or protruding very slightly posteriorly. Vestiture consisting of sparse flattened bristles, mostly on declivity, not more than about six or seven on any one interstriae. Interstriae 10 acutely elevated only to level of hind coxae.

Male.-Similar to female except frons convex above level of antennal insertions, transversely impressed between that level and epistomal process, sparsely punctured.

Distribution.- Costa Rica.
COSTA RICA: Playón, San José, 9-Vili-63, 50 m , No. 120, balsa, S. L. Wood.

## Host.- Ochroma velutina.

Biology. - This species was taken from newly formed, oval nuptial chambers in the phloem tissues of recently cut balsa limbs. Eggs were scattered indiscriminately in the chamber; larvae were not present.

Notes.- The above treatment was based on the type series of 39 specimens.

## 39. Scolytodes culcitatus (Blandford)

## Epomadius culcitatus Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):179 (Lectotype, female?; Peńa Blanca, Chiriquí, Panama; British Mus. Nat. Hist., present designation)

Diagnosis.- This unique species has the anterior half of the lateral margins of the pronotum concavely impressed on a large, circular area that is densely pubescent. Except for this unique character, this species is a normal representative of this genus.

Female (?).- Length $2.4 \mathrm{~mm}, 2.1$ times as long as wide; color dark reddish brown. Sex not determinable in specimens at hand.

Frons weakly concave, surface evidently subreticulate, minutely punctured, and almost devoid of vestiture, as in most males of this genus; frons not fully visible in specimens at hand.

Pronotum 1.1 times as long as wide; widest at middle, apparently very strongly constricted on anterior half, constriction filled by dense pubescence, anterior margin broadly rounded; anterior half declivous, rather strongly asperate; posterior area strongly reticulate, punctures minute, most of them minutely asperate; lateral margin on posterior half marked by a raised line, anterior half concavely impressed on a large subcircular area invading tergum and pleuron equally, concavity filled by dense, fine, long, yellow hair. Vestiture on dorsal areas fine, short, rather abundant.

Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; sides straight on basal half, diverging slightly to base of declivity, rather narrowly rounded behind; striae not impressed, obscure but discernible, punctures rather small, deep, slightly irregular; interstriae about three or four times as wide as striae, smooth, punctures as large as those of striae, rather abundant, confused. Declivity rather steep, convex; punctures very small, close, completely confused, striae entirely obsolete. Vestiture of very fine, rather abundant, moderately long hair.

Distribution. - Panama.
PANAMA: Peña Blanca, Chiriquí, 3000-4000 ft ( $1000-1300 \mathrm{~m}$ ), G. C. Champion.

Notes.- The above treatment was prepared from the syntypic series of two specimens of the same sex, presumably females. The first of these syntypes is here designated as the lectotype of Epomadius culcitatus Blandford. This specimen bears a type label and has been regarded as the type for many years, although it has not previously been so designated.

## 40. Scolytodes spadix (Blackman)

Prionosceles spadix Blackman, 1943, Proc. U.S. Nat. Mus. 94:384 (Holotype, male; intercepted at New York in log from Guatemala: U.S. Nat. Mus., 56562)

Diagnosis.- Apparently rather closely allied to swieteniae Blackman, but differing as indicated below.

Male.- Length $1.9 \mathrm{~mm}, 2.1$ times as long as wide; color reddish brown.

Frons as in male swieteniae, except less strongly reticulate.

Pronotum 1.06 times as long as wide; slightly more elongate than swieteniae, posterior two-fifth devoid of asperities and granules, punctures rather close, coarse, surface mostly smooth, shining. Glabrous.

Elytra 1.1 times as long as wide, 1.1 times as long as pronotum; outline similar to swieteniae except more broadly rounded behind; disc occupying basal half; striae distinctly impressed, punctures rather small, deep; interstriae 1 constricted near base causing striae to appear sinuate, surface smooth, shining, punctures rather small, close, confused. Declivity rather broadly convex, striae 1 moderately impressed; interstrial punctures smaller than on disc, less strongly confused. Vestiture confined to odd-numbered declivital interstriae, consisting of rather widely spaced, slender bristles, each about equal in length to width of an interstriae.
Distribution.-Guatemala?
guatemala: Intercepted at New York, 26-V-41, No. 89860 in hybrid mahogany log from Guatemala.

Notes.- The above treatment was based on the unique holotype.

## 41. Scolytodes swieteniae (Blackman)

Hexacolus swieteniae Blackman, I943, Proc. US. Nat. Mus. 94(3174):381 (Holotype, female; Costa Rica; U.S. Nat. Mus., 56559)

Diagnosis.- This species is doubtfully distinct; possibly it is a geographical race of guyanensis (Schedl); it is distinguished in the female by the more strongly elevated frontal prominence, with the coarsely reticulate area above the prominence not carinate or sharply defined laterally; the male carina just above the epistoma is more sharply defined.
Female.- Length $1.7-1.8 \mathrm{~mm}, 1.9$ times as long as wide; color reddish brown.

Frons flattened from epistoma to vertex, with a fine, sharply elevated median carina from epistomal margin to level of antennal insertion, carina ascends abruptly and ends at level of antennal insertion in a central prominence occupying central fourth to a point slightly below upper level of eyes, prominence sharply rugose-reticulate, remaining surface shining, obscurely reticulate, with a few very fine punctures; area above eves ornamented by a dense brush of long, yellow hair, tips of some hairs attaining level of antennal insertion.

Pronotum 1.0 times as long as wide; widest at base, very feebly, arcuately converging on posterior two-thirds, rather broadly rounded in front; anterior half rather coarsely, closely asperate, asperities in central area decreasing in size and number but extending to base; surface shining, obscurely reticulate, sparse, fine punctures in lateral areas becoming subasperate toward median area. Glabrous.

Elytra 1.2 times as long as wide, 1.2 times as long as pronotum; sides feebly arcuate, almost parallel on basal half, rather narrowly rounded behind; striae 1 moderately, others not impressed, punctures rather fine, deep; interstriae three to four times as wide as striae, smooth, brightly shining, punctures minute, deep, irregularly uniseriate. Declivity convex, rather steep; striae 1 strongly impressed; interstriae slightly narrower. Almost glabrous, a few very minute hairs somtimes occuring on declivity.

Male.- Similar to female except frons moderately convex above level of antennal insertion, central prominence absent, median carina on lower third as in female; pronotal asperities slightly larger and more abundant; strial punctures much smaller, equal in size to those of interstriae in one specimen.

Distribution.- Costa Rica.

COSTA RICA: Intercepted in mahogany logs from Costa Rica at the New York Quarantine Station, I8-V41, and from cedar logs 3-1X-41.

Hosts.-Swietenia sp., Cedrela sp.
Notes.- The above treatment was based on the holotype and on four specimens from cedar logs. Blackman's type is a female, not a male as stated in the original description.

## 42. Scolytodes cedrelae Wood

Scolytodes cedrelae Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):19 (Holotype, female; Rincón de Osa, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- Very closely related to swieteniae (Blackman), but the frontal carina does not attain the epistomal margin in either sex, and the female carina (somtimes double) begins well above the epistoma; in addition, the female of this species has the lower frons more distinctly punctured and ornamented by sparse hair; the tuft of hair on the vertex also extends ventrad to a point in line with the anterior margin of the eve; this tuft in swieteniae ends well above that point.

Female.- Length $1.3-1.5 \mathrm{~mm}, 2.2$ times as long as wide; color yellowish brown, with anterior and posterior ends and elytral suture dark.

Frons flattened from vertex to epistoma; middle half between upper level of eyes bearing a low median carina of uniform height; epistomal margin and sides near antennal bases rather coarsely, deeply punctured; vestiture consisting of a dense brush of long, yellow hair on vertex extending downward laterally to anteromesal angle of eye; sparse hair scattered on lower area.

Pronotum 1.1 times as long as wide; sides subparallel on basal half, converging slightly to anterior fourth, then broadly rounded in front; summit indefinite, near middle; anterior half armed by numerous, close, shining, narrow crenulations; posterior half reticulate, dull, with very fine, obscure punctures, and in discal area with small, transverse, shining granules extending to base.

Elytra 1.2 times as long as wide, 1.1 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, rather narrowly rounded behind; striae not impressed, punctures moderately large, shallow; interstriae almost twice as wide as
striae, almost smooth, subshining, punctures obscure, uniseriate. Declivity steep, convex; striae 1 and possibly 2 weakly impressed, punctures of striae and interstriae small and deeper than on disc. Vestiture consisting of a few flattened bristles on alternate odd interstriae, mostly on declivity.

Male.-Similar to female except frons convex, with a weak transverse impression just above epistoma, surface reticulate and sparsely punctured.

Distribution.- Costa Rica.
COSTA RICA: Rincón de Osa, Puntarenas, 11-VIII66, 100 m , No. 48, Cedro macho: Río Damitas, Dota Mts., San José, 22-VII-63, 250 m . No. I31, Vismia guiancusis: both by me.

Host.-Cedrela mexicana, Vismia guianensis.

Biology.- This species was collected from the phloem tissues of large logs of three host species, one of which was cedro amargo. The old tumnels were primarily transverse, but were too dense to definitely determine a pattern.

Notes. - The above treatment was based on the type series of 63 specimens.

## 43. Scolytodes schucarzi (Hopkins) Figs. 27, 142

Erincophilus schwarzi Hopkins, 1902, Proc. Ent. Soc. Washington 5:36 (Holotype male; Coconut Grove, Dade Co., Florida; U.S. Nat. Mus.. 7394)
Diagnosis.- This species is very closely related to facetus Wood, but it may be distinguished by the much coarser punctures and shining surfaces of pronotum and elytra.

Female.- Length 1.3-1.6 mm, 2.4 times as long as wide; color yellowish brown, often with anterior area of pronotum and lower half of elytral declivity slightly darker.

Frons weakly concave, central third smooth, polished, glabrons, remaining area finely granulate-punctate and bearing a brush of long, yellow hair.

Pronotum 1.1 times as long as wide; widest at base, sides almost straight, very indistinctly converging on basal two-thirds, rather broadly rounded in front; asperities moderately large, close, on more than anterior half; anterior margin armed by a low, irregular, almost
continuous row of crenulations; posterior third shining, obscurely reticulate in some specimens, coarsely, deeply, closely punctured, interspaces equal to less than half width of a puncture. Glabrous.

Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures rather coarse, deep, close; interstriae almost twice as wide as striae, smooth, shining, punctures coarse, deep, uniseriate, two-thirds as large as those of striae. Declivity convex, rather steep; all punctures smaller than on disc, those of interstriae about equal in size to those of striae. Glabrous.

Male. - Similar to female except frons convex, reticulate, dull, punctures minute, sparse, tuft of hair absent.

## Distribution.-S Florida to Veracruz.

USA: Florida: Miami, 23-VIII-60, Ficus carica, J. R. McFarlin; Perrine, 23-VI-51, Ficus aurea, S. L. Wood; Everglades N.P.. 6-VII-51, Ficus auria, S. L. Wood: Key Largo, 25-VI-5I, Ficus aurca and brcrifolia, S. L. Wood; Plantation Key, 3-V-67, D. E. Bright. MEXICO: Veracruz: Mandinga, 12-III-80. Ficus. T. H. Atkinson.

Fig. I42. Scolytodes schuarzi: 1, 2, adult female: a, antenna; b, maxilla; c, male labium; d, female labium; $e$, tibia, anterior aspect: f, tarsus; g, epistoma; $h$, prosternum; $i$, section of elytra: $j$, section of pronotum; $k$, apices of elytra and abdomen. (After Hopkins 1902:35.)

Hosts.- Ficus spp.
Biology.- This species infests unthrifty branches in healthy trees and broken or cut branches. The tunnels are typical of the genus.

Notes.- The above treatment was based on 73 specimens.

## 44. Scolytodes facetus Wood

Scolytodes facctus Wood, 1967, Great Basin Nat. 27:126 (Holotype, female; Palín, Esquintla, Guatemala; Wood Coll.)
Diagnosis.- This species is distinguished from ficivorus Wood by the very fine, somewhat obscure punctures of pronotum and elytra, by the slightly longer and more abundant vestiture on the female frons, and by the more narrowly separated eyes.
Female.- Length 1.6 mm , males $1.4-1.5$ $\mathrm{mm}, 2.3$ times as long as wide; color yellowish brown.

This species differs from ficivorus in having eyes separated by 1.6 times width of an eye ( 2.6 times in ficicorus); elytra reticulate, with punctures shallow, those of interstriae obscure. Obscure, minute pronotal punctures separated by distances at least twice their own diameters (this distance less than diameter of a puncture in ficivorus).

Male. - Similar to female except frons convex, reticulate, obscurely punctured; eyes separated by 2.1 times width of an eye (3.1 in ficivorus).

Distribution.-Guatemala.
GUATEMALA: Palín. Esquintla, 19-V-64, 300 m , No. 584. Ficus, S. L. Wood.

Brology.- This species and ficilorus infested the same small, broken branch of a mature fig tree. Differences in habits between the two species were not observed.

Notes.- The above treatment was based on the type series of four specimens.

## 45. Scolytodes piceus (Blandford)

Hexacolus piceus Blandford, 1897, Biol. Centr. Amer., Coleopt. 4(6):183 (Lectotype, male; Volcán de Chiriqui, Chiriquí, Panama; British Mus. Nat. Hist., present designation)
Diagnosis.- In the above key this species is placed near facetus Wood and schwarai Hopkins, but the relationship is remote; the pronotum is much more finely sculptured and the female frons is very different.

Female.- Length 1.9-2.1 mm, 2.5 times as long as wide; color dark reddish brown.

Frons narrow, flattened from epistoma to vertex, central third on lower half smooth, shining, remaining area rather finely, deeply, closely punctured, margins of upper half and on vertex bearing a dense brush of long yellow hair, tips of some setae attaining epistomal margin.

Pronotum 1.1 times as long as wide; sides almost straight, converging very slightly on basal two-thirds, rather narrowly rounded in front; anterior third finely asperate, anterior margin unarmed; surface on posterior twothirds finely, deeply reticulate, rather dull, punctures fine, shallow, moderately close. Glabrous.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on slightly less than basal two-thirds, rather broadly rounded behind; striae I feebly, others not impressed, punctures rather small. deep; interstriae about twice as wide as striae, surface smooth, shining, punctures fine, deep, uniseriate. Declivity convex, rather steep; all punctures slightly smaller than on disc, those of interstriae tending to be confused. Glabrous, except some specimens with very minute, fragile hair on lower area of declivity.

Male. - Similar to female except frons convex, a broad, transverse impression just above epistoma, surface finely reticulate, a few minute punctures.

Distribution.- Costa Rica to Panama.
COSTA RICA: Tapantí, Cartago, 1300 m, 17-IN-63, No. 180, tree branch, 26-X-63, No. 265 in Phoebea mexicana, No. 266 in Cecropia mexicama branch: all by me. PANAMA: Volcán de Chiriquí, G. C. Champion.

Hosts.- Cecropia peltata, Phoebea mexicana.

Brology.- This monogamous species was taken from tree branches about 5 cm in diameter, mostly in the outer bark, although some tunnels reached the cambium region.

Notes.- The above treatment was based on the male lectotype and on 66 other specimens. The first of Blandford's two syntypes is a male that for many years has borne a label identifying it as the type, although it has never been so designated. I here designate that male, from Volcán de Chiriquí, as the lectotype of Hexacolus piceus Blandford.
46. Scolytodes obesus Wood

Scolytodes obesus Wood, 1975, Great Basin Nat. 35:26 (Holotype, female; Barro Colorado Island, Canal Zone, Panama; Wood Coll.)
Diagnosis.- This species is distinguished from the remotely related immanus Wood by the smaller size, by the stouter body form, by the pair of carinae on the female frons, and by other characters.

Female.-Length $1.8 \mathrm{~mm}, 2.1$ times as long as wide; color yellowish brown, anterior third of pronotum darker.

Frons shallowly, broadly concave from level of antennal insertion to upper level of eyes (upper area concealed by pronotum), surface smooth and shining except subreticulate near margins; epistomal area from margin to level of antennal insertion longitudinally divided into equal thirds by a pair of rather strongly elevated carinae; premandibular epistomal lobe large, conspicuous, pubescent; vestiture mostly confined to margins of upper half of frontal area, consisting of a row of long, subplumose setae, longest setae equal to about one-half to two-thirds distance between eyes.

Pronọtum 0.97 times as long as wide; widest near base, sides weakly, arcuately converging on basal two-thirds, rather broadly rounded in front; anterior third moderately declivous, finely asperate; posterior areas reticulate, very finely, rather closely punctured. Glabrous except for an occasional coarse seta on asperate area.
Elytra 1.15 times as long as wide, 1.25 times as long as pronotum; sides almost straight on basal half, slightly wider at base of declivity, rather broadly rounded behind; disc confined to basal half; striae not impressed, punctures small, rather shallowly impressed, spaced by distances equal to diameter of a puncture; interstriae four times as wide as striae, smooth, shining, punctures small to minute, weakly impressed; interstriae 10 weakly carinate to level of sternum 5. Declivity convex, moderately steep; sculpture as on disc. Vestiture of sparse, moderately long bristles on odd-numbered interstriae.

Protibiae slender, lacking minute tooth on posterior face near tarsal insertion.

Distribution.- Panama.
PANAMA: Barro Colorado Island, Canal Zone, 7-VIII-67, L. and C. W. O'Brien.

Notes.- The above treatment was based on the holotype.

## 47. Scolytodes immanis Wood

Scolytodes immanis Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. IO(2):19 (Holotype, female; Villa Mills near Cerro de la Muerte, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- Most of the known species allied to immanis are from South America. In the Central American fauna it is most nearly allied to alni Wood, but it may be distinguished by the larger size, by the uniseriate strial punctures, by the smaller pronotal punctures, and by the stouter body form.

Female.- Length $3.5 \mathrm{~mm}, 2.4$ times as long as wide; color very dark brown on head, anterior half of pronotum, elytral suture, and underparts, light yellowish brown on posterior half of pronotum, elytra, and legs.

Frons flattened from well above upper level of eyes to epistoma, with median third of lower half very feebly impressed; impressed area smooth, shining, remaining lateral and dorsal areas rather coarsely, closely, shallowly punctured; vestiture consisting of coarse, long subplumose, yellow hair on punctured area, a majority of setae arising above upper level of eyes, tips of some of those on vertex almost attaining level of antennal insertion.

Pronotum 1.04 times as long as wide; sides almost straight and parallel on basal twofifths, then arcuately converging to rather narrowly rounded anterior margin; dorsal profile arched from base to anterior margin, indefinite summit on basal half; minutely, closely asperate in front of summit, reticulate and minutely, rather obscurely punctured behind. Glabrous except for a few small setae at anterolateral angles.

Elytra 1.5 times as long as wide, 1.9 times as long as pronotum; sides almost straight, widest near base of declivity, narrowly rounded behind; striae not impressed, punctures fine, shallow, in definite rows; interstriae three times as wide as striae, almost smooth, punctures smaller than those of striae, shallow, rather numerous, confused. Declivity convex, rather steep; striae 1 and perhaps interstriae 2 weakly impressed on middle third. Glabrous.

Distribution.- Costa Rica.

COSTA RICA: Villa Mills near Cerro de la Muerte, Cartago, I-VIll-66, 3100 m , No. 44, Miconia, S. L. Wood.

Biology.- Specimens were removed from a pith cavity in a terminal branch of a tree seedling.

Notes.- The above treatment was based on the type series of two female specimens.

## 48. Scolytodes alni Wood

Scolytodes alni Wood. 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 20$ (Holotype, female: Volcán Irazu, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- Rather closely related to piceus (Blandford), but larger, and striae 3-5 with punctures somewhat confused.

Female.- Length 2.4-2.9 mm, 2.5 times as long as wide; color dark brown.

Frons flattened from vertex to epistoma, surface coarsely, closely punctured; upper half ornamented by a dense brush of very long hair, tips of some attain epistomal margin; epistomal lobe very small.

Pronotum 1.1 times as long as wide; widest near base, sides almost straight, converging very slightly to anterior fourth, then rather narrowly rounded in front; summit near middle; anterior half finely, densely asperate: reticulate and finely, rather sparsely punctured behind. Glabrous.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae feebly impressed at least toward base, punctures fine, distinct; interstriae at least twice as wide as striae, marked by transverse lines, punctures almost equal in size to those of striae, confused, rather close. Declivity steep, convex; strial punctures smaller and deeper than on disc, interstrial punctures distinctly smaller than those of striae. Glabrous.

Male.- Similar to female except frons convex, weakly impressed just above epistoma, its surface shining, subreticulate, with sparse, fine punctures.

Distribution.- Costa Rica.
COSTA RICA: Volcán Irazu, Cartago, 28-Vti-63, No. 3, and 26-X-63, No. $214,2300 \mathrm{~m}$, both from Alnus, by me.

## Host.- Alnus acuminata.

Biology.-Stumps of recently cut alder trees were selected for attack. The galleries
were in green, healthy tissue along the margins of tears or cuts in the bark. The entrance tunnel commenced at or near the cambium where the bark was torn. The galleries were slightly wider than the length of a beetle, somewhat irregular but mostly longitudinal. The upper half of the gallery usually turned transversely and often branched. The wood was engraved very lightly; eggs occurred only on the lower side and were scattered indiscriminately. The larvae fed in congress.

Notes.- The above treatment was based on the type series of 45 specimens.

## 49. Scolytodes erineophilus Wood

Scolytodes crineophilus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):20 (Holotype, female; Tapantí, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- This species is allied to ficivorus Wood and marginatus Wood, but it may be distinguished by characters summarized in the above key.

Female.- Length $1.4-1.6 \mathrm{~mm}, 2.4$ times as long as wide; color medium brown.

Frons feebly convex, almost flat, on a rather narrow area from just below upper level of eyes to epistomal margin; surface etched by minute, transverse lines in central half of flattened area, remainder of flattened area rather coarsely, not closely punctured; convex area above reticulate, with sparse, fine punctures; vestiture consisting of sparse, fine, long hair on punctured part of flattened area, remainder of flattened area rather coarsely, not closely punctured; convex area above reticulate, with sparse, fine punctures; vestiture consisting of sparse, fine, long hair on punctured part of flattened area, not conspicuous.

Pronotum 1.0 times as long as wide; widest at base, sides very feebly arcuate, almost straight, converging anteriorly, then rather strongly, not abruptly rounded to broadly rounded anterior margin; finely, closely asperate on anterior half, asperities decreasing in size and density behind, continued as very fine transverse granules to basal fourth; posterior surface and spaces between asperities strongly reticulate, finely, rather sparsely punctured behind, anterior rims of punctures granulate except on basal fourth. Vestiture sparse, inconspicuous, confined to anterior and lateral areas.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, narrowly rounded behind; striae not impressed, punctures small, distinct, rather deep; interstriae about one and one-half times as wide as striae, subshining, punctures about two-thirds as large as those of striae, uniseriate. Declivity moderately steep, convex; strial and interstrial punctures greatly reduced in depth and clarity, obscure. Vestiture rather abundant, consisting of short, fine, semirecumbent strial and interstrial hair, interstrial setae on and near declivity longer, erect, stout, somewhat flattened.

Male.-Similar to female except frons weakly convex, reticulate, finely, sparsely punctured, frontal vestiture shorter, less abundant; a few scattered, erect bristles on interstriae 1,3 , and 5 almost to elytral base.
Distribution.- Costa Rica.
COSTA RICA: Tapanti, Cartago, 17-VIII-63, 1300 m , No. 101, Ficus, S. L. Wood.

Biology.-Galleries were made in phloem tissues of unthrifty twigs less than 1 cm in diameter in a living native fig tree.

Notes.- The above treatment was based on the type series of 22 specimens.

## 50. Scolytodes ficivorus Wood

Scolytodes ficicorus Wood, 1967, Great Basin Nat. 27:125 (Holotype, female, Paulin, Guatemala; Wood Coll.)
Diagnosis.- This species is very closely related to schwarzi (Hopkins), but it may be distinguished by the more coarsely punctured, less shining pronotum and elytra, by the reticulate pronotal dise, by the more finely asperate anterior area of the pronotum, and by the somewhat more coarsely punctured marginal areas of the female frons. Additional data eventually may prove this to be only a subspecies of schwarzi.

Female.- Length $1.5-1.7 \mathrm{~mm}, 2.3$ times as long as wide; color yellowish brown.

Except for the characters noted in the above diagnosis, this species appears to be identical to schwarzi.

Male. - Similar to female except frons convex, reticulate, obscurely punctured, with frontal vestiture greatly reduced.

Distribution.-Guatemala.
GUATEMALA: Palín, Esquintla, 19-V-64, 300 m , No. 584, Ficus, S. L. Wood.

Brology.- This species infested phloem tissues in a small broken branch of a native fig tree.

Notes.- The above treatment was based on the type series of four specimens.
51. Scolytodes reticulatus (Wood)

Hexacolus reticulatus Wood, 1961, Great Basin Nat. 21:98 (Holotype, female; 19 km SE Matamoros, Puebla, Mexico; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species is allied to ficivorus Wood, although the relationship is not particularly close. It may be distinguished by the reticulate elytra, by the much finer punctures on elytra and pronotum, and by other characters included in the key.

Female.- Length $1.5-2.0 \mathrm{~mm}, 2.2$ times as long as wide; color reddish brown.

Frons flattened from epistoma to slightly below upper level of eyes, central fourth on lower half smooth, shining, slightly elevated, remaining area rather coarsely, deeply, not closely punctured, punctures separated by distances equal to diameter of a puncture; vestiture of long, yellow hair arising in equal (moderate) density from all margins except epistoma, epistomal brush also present.

Pronotum 1.02 times as long as wide; widest at base, sides weakly arcuate, distinctly converging on basal two-thirds, rather narrowly rounded in front; anterior margin armed by a low, irregular row of contiguous crenulations; anterior third declivous, rather coarsely asperate, a few small asperities to middle; surface strongly reticulate, dull or subshining, punctures rather small, shallow, moderately close. Glabrous.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures rather small, shallow, spaced in a row by width of a puncture; interstriae about twice as wide as striae, entire surface reticulate, subshining, punctures moderately small, uniseriate. Declivity convex, rather steep; all punctures reduced in size, those of interstriae minute. Glabrous.

Male. - Similar to female except frons moderately convex, entire surface reticulate, sparsely, shallowly punctured; asperities on pronotum usually coarser; interstrial
punctures confused toward declivity on some specimens.

Distribution.- Morelos to Puebla and Michoacán.

MEXICO: Michoacán: La Gallina, 1-1X-80, Ficus, S146. T. H. Atkinson. Morelos: Las Piedras, 17-VII-80, Ficus petiolaris, T. H. Atkinson. Puebla: 20 km SE Izúcar de Matamoros, 3-VII-63, Ficus, S. L. Wood.

Biology.- Specimens were collected from the bark of branches of strangler fig.

Notes.- The above treatment was based on the type series of 69 specimens.

## 52. Scolytodes marginatus Wood

Scolytodes marginatus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):21 (Holotype, female; Dominical, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- This species is allied to reticulatus Wood, but it may be distinguished by the more slender body form, the more deeply impressed striae, the smooth interstriae, and the interstrial setae.

Female.- Length $1.5-1.7 \mathrm{~mm}, 2.9$ times as long as wide; body color rather light brown.

Frons broadly plano-convex from upper level of eyes to epistoma, a shining median carina beginning as a fine line near center, becoming broader and somewhat higher, then ending abruptly just above epistomal margin; surface reticulate, finely, sparsely punctured, punctures larger and deeper near margins of flattened area; vestiture confined to marginal areas, consisting of fine, rather abundant, moderately long hair.

Pronotum 1.2 times as long as wide; sides straight and parallel on basal two-thirds, evenly, rather broadly rounded in front; anterior margin armed by 10 teeth; strongly declivous and asperate on anterior third, asperities rather large and broad, many of them arranged in broken subconcentric rows; posterior area reticulate, rather coarsely, closely punctured. Vestiture confined to asperate and lateral areas, disc glabrous.

Elytra 1.6 times as long as wide, 1.4 times as long as pronotum; sides straight and parallel on basal two-thirds, rather narrowly rounded behind; striae narrowly impressed, punctures small, shallow; interstriae about one and one-half times as wide as striae, moderately convex, smooth, punctures small, rather sparse, some minutely subvulcanate,
uniseriate. Declivity steep, convex; striae 1 rather strongly impressed, others less strongly impressed than on disc; strial and intrestrial punctures somewhat finer; interstriae 1 slightly elevated. Vestiture consisting of fine, erect, rather long, interstrial hair.

Anterior coxae subcontiguous.
Male.-Similar to female except frons broadly convex, coarsely, closely, deeply punctured, with a smooth, shining, slightly elevated callus on lateral fourth of epistomal margin; elytral vestiture consisting of apically flattened bristles.

Distribution.- Chiapas to Costa Rica.
MEXICO: Chiapas: Palenque Ruins, 9-V-69, D. E. Bright. COSTA RICA: Dominical, Puntarenas, 9-IX-63, 3 m, No. 297, S. L. Wood.

Biology.- Specimens were removed from phloem tissues of small, unthrifty twigs of a large, unidentified tree. Because of the starshaped tunnels, this species was thought to be a Pityophthorus species, and sufficiently detailed notes were not recorded. Evidently it is polygamous.

Notes.- The above treatment was based on the type series of 10 specimens.

## 53. Scolytodes impressus Wood

Scolytodes impressus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 22$ (Holotype, male; Turrialba, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- This unique species has large and very strongly impressed strial punctures for this genus, and it has interstrial rows of spatulate bristles.

Male.- Length $1.3-1.7 \mathrm{~mm}, 2.6$ times as long as wide; color rather dark, reddish brown.

Frons convex except transversely impressed along epistoma; surface obscurely reticulate, subshining, with rather fine, sparse, sharp punctures, except close and deep along epistoma; vestiture largely confined to epistoma.

Pronotum 1.2 times as long as wide; sides straight and parallel on basal two-thirds, rather broadly rounded in front; anterior third finely, closely asperate; posterior half subshining, obscurely reticulate toward indefinite summit, a few minute points present, punctures coarse, close, deep, separated by less than diameter of a puncture; vestiture obscure, on asperate and lateral areas.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae 1 moderately, others weakly impressed, punctures coarse, deep; interstriae as wide as striae, shining, punctures fine, some indistinct, uniseriate. Declivity convex, steep; striae, particularly 1 , more strongly impressed than on disc; interstriae 1 slightly elevated; punctures not reduced in size; vestiture consisting of apically flattened, interstrial bristles on dise and declivity, distance between rows and between bristles in a row about equal to length of a bristle.

Distribution.- Costa Rica.
COSTA RICA: Turrialba, Cartago, 3-III-64, 600 m , No. 459, tree limb, S. L. Wood.

Biology.- This species was just entering a large broken limb of an unidentified tree; consequently, galleries were not developed. It was associated in the same limb with Phloeotribus furvus Wood and P. demissus Blandford.

Notes.- The above treatment was based on the type series of 30 specimens, presumably all males.

## 54. Scolytodes pelicipennis (Schedl)

Hexacolus pelicipennis Schedl, 1952, Dusenia 3:356 (Holotype, male; Jiménez, Osa Peninsula, Puntarenas, Costa Rica; Schedl Coll.)
Diagnosis.- This species is distinguished from impressus Wood by the stouter body form and by differences in the sculpture of the pronotum and elytra as indicated below.

Male.- Length $1.2 \mathrm{~mm}, 2.3$ times as long as wide; color light brown.

Frons convex, reticulate, punctures fine, rather close; vestiture inconspicuous.

Pronotum 1.05 times as long as wide; as in impressus except asperities much wider, discal punctures much larger, interspaces smooth, averaging less than half as wide as diameter of a puncture. Glabrous.

Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; about as in impressus except striae more strongly impressed, punctures slightly larger, interstriae narrower than striae, convex, smooth, punctures fine, uniseriate. Declivity convex, steeper than in impressus; sculpture as on disc except striae weakly impressed, punctures more deeply impressed.

Distribution.- Costa Rica.
COSTA RICA: Jiménez, Osa Halbinsle, E. Reimoser.
Notes.- The above treatment was based on the holotype.

## 55. Scolytodes rugicollis (Schedl)

Hexacolus rugicollis Schedl, 1940, Arb. Morph. Taxon. Ent. Berlin-Dahlem 7:205 (Lectotype, female; Hamburgfarm on Rio Reventazón, Limón, Costa Rica, designated by Wood, 1974, Great Basin Nat. 34:287)
Scolytodes plicatus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):21 (Holotype, female; 25 km SE Guápiles, Limón, Costa Rica; Wood Coll.); Wood, 1974. Great Basin Nat. 34:287. Synonymy
Diagnosis.- This species and pannuceus Wood are unique in having the pronotal asperities exceedingly broad and the anterior margin of the pronotum a continuous, elevated costa. These two species may be distinguished from one another by characters summarized in the above key.

Female.- Length $1.5-1.8 \mathrm{~mm}, 2.5$ times as long as wide; color rather light brown.

Frons mostly convex, subconcavely impressed on central third, a broad, shining callus surrounding lower third of impression; surface rather finely punctured at sides and above to well above upper level of eyes; vestiture fine, hairlike, moderately long and abundant on punctured area.

Pronotum 1.1 times as long as wide; widest at base, sides almost straight on posterior two-thirds, converging slightly anteriorly, broadly rounded in front; anterior third rather strongly declivous, asperities rather low, sharply raised, very broad, some as much as a fourth total width of pronotum; anterior margin armed by a continuous costa; posterior half reticulate, with fine, shallow punctures. Glabrous except for a few bristles on anterior margin.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; striae 1 weakly, others not impressed, punctures small, shallow, not sharply defined; interstriae subreticulate, almost twice as wide as striae, punctures fine, shallow. Declivity convex, moderately steep; striae 1 narrowly impressed; all punctures smaller and somewhat deeper than on disc. Vestiture consisting of a few sparse, erect, declivital hairs on odd-numbered interstriae.

Male.-Similar to female except frons convex, reticulate, with a few obscure punctures, subglabrous.

Distribution.- Costa Rica.
COSTA RICA: 25 km SE Guápiles, Limón, 22-vili$66,100 \mathrm{~m}$, No. I04, Ficus, S. L. Wood.

Biology.- This species was taken from phloem tissues in the limb of a large, recently cut, native fig tree.

Notes.- The above treatment was based on the lectotype of rugicollis, on the holotype of plicatus, and on 11 other specimens.

## 56. Scolytodes pannuceus Wood

Scolytodes pannuceus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):16 (Holotype, female: La Ceiba, Atlántida, Honduras; Wood Coll.)
Diagnosis.- This species and rugicollis (Schedl) are unique in having unusually broad, costiform, pronotal asperities. This species is distinguished from plicatus by the smaller, shallow strial and interstrial punctures, and by the very different sculpture of the female frons.

Female.- Length 1.7 mm (male 1.5 mm ), 2.4 times as long as wide; color yellowish brown.

Frons flattened from epistoma to upper level of eyes, surface minutely, densely pilose over almost entire flattened area; epistomal margin very slightly elevated, smooth, shining, a narrow median extension reaching level of antennal insertion; lateral and upper extreme margins bearing a row of long, yellow hair.

Pronotum and elytra as in plicatus except pronotal punctures slightly larger, strial and interstrial punctures much larger and deeper.

Male.- Similar to female except frons convex, reticulate, punctures moderately large, shallow, rather sparse, subglabrous; pronotal asperities slightly larger; pronotal and elytral punctures distinctly finer.

Distribution.- Honduras.
honduras: La Ceiba, Atlántida, 7, 17-VI-49, at light, E. C. Becker.

Notes.- The above treatment was based on the type series of two specimens.

## 57. Scolytodes multistriatus (Wood)

Hexacolus multistriatus Wood, 1961, Great Basin Nat. 21:97 (Holotype, female; 8 km W Villa Juarez, Puebla, Mexico: Wood Coll.)

Diagnosis.- This distinctive species is not closely related to any other species known to me. The size, coarse strial and interstrial punctures, and declivital interstrial granules distinguish it from all others.

Female.- Length $1.7-2.2 \mathrm{~mm}, 2.4$ times as long as wide; color very dark brown.

Frons flattened from epistoma to upper level of eyes, surface smooth, closely, rather coarsely, deeply punctured over entire surface; pubescence rather sparse on lower half, becoming dense and much longer on upper third and to vertex, distributed over entire surface.

Pronotum 1.1 times as long as wide; widest at base, sides almost straight, indistinctly converging on basal two-thirds, rather narrowly rounded in front; anterior margin armed by a continuous, undulating, elevated costa; anterior half coarsely asperate; posterior areas weakly reticulate, shining, punctures coarse, deep, moderately close. Glabrous.

Elytra 1.5 times as long as wide; sides almost straight and parallel on more than basal two-thirds, rather broadly, subobtusely rounded behind; striae not impressed, punctures rather coarse, close, deep; interstriae slightly less than twice as wide as striae, smooth, shining, punctures equal (occasionally slightly smaller) in size, depth and spacing to those of striae. Declivity convex, steep; punctures slightly smaller, interstriae armed on upper half by rows of rather widely spaced, rounded granules. Subglabrous, a few interstrial bristles on declivity.

Male. - Similar to female except frons convex above level of antennal insertion, transversely impressed below, a short, longitudinal, median carina in impressed area, surface reticulate, coarsely, not closely punctured above, finely below.

Distribution.- Puebla.
MEXICO: Puebla: 10 km NE Teziutlán, 2-VII-67, No. 134; 8 km W Villa Juárez, 25-VI-53, No. 37; all by me.

Biology.- One series was removed from a broken limb about 7 cm in diameter, the other from a tree bole 20 cm in diameter. The larvae and adults were xylophagous. The galleries were of the radiate type and contained from one to four females with each male.

Notes.- The above treatment was based on the type series of 34 specimens and on 48 other specimens.

## 58. Scolytodes pelicerinus (Schedl)

Hexacolus pelicerinus Schedl, 1952, Dusenia 3:358 (Holotype, male?; Mexico?; Schedl Coll.)
Diagnosis.- This species is distinguished from multistriatus (Wood) by the much smaller size, by the more slender body form, by the longer pubescence on the female frons, by the more narrowly convex elytral declivity, which entirely lacks granules, and by the sparse elytral setae.

Female.- Length 1.3-1.5 mm, 2.5 times as long as wide; color dark reddish brown.

Basicaily as in multistriatus except as indicated in diagnosis.

Distribution.- Puerto Rico.
Puerto RICO: 19 km E Mayaguez, 8-II-69, C. W. O'Brien.

Notes.- The above treatment was based on the holotype, which was thought to have been taken in Mexico, and on five specimens from Puerto Rico. There is no evidence that this species belongs either to the Mexican or Central American fauna.

## 59. Scolytodes pubescens Wood

Scolytodes pubescens Wood, 1969, Brigham Young Univ. Sci. .Bull., Biol. Ser. 10(2):21 (Holotype, female; San Ignacio de Acosta, San José, Costa Rica; Wood Coll.)
Diagnosis.- This species is allied to ingavorus Wood, but it may be distinguished by characters summarized in the above key.

Female.- Length $1.5-1.8 \mathrm{~mm}, 2.4$ times as long as wide; color rather dark brown, elytra and basal half of pronotum lighter.

Frons subconcavely impressed on slightly more than median half, with a pair of shining, rather strongly elevated, longitudinal carinae at lateral margins of concavity; surface of frontal area except carinae finely, closely granulate-punctate; vestiture consisting of rather coarse, moderately long setae, rather sparse in concave area, rather dense lateral to carinae and continuing above to a level slightly above upper level of eyes, not longer above.

Pronotum 1.1 times as long as wide; widest at base, sides very weakly arcuate on basal two-thirds, rather narrowly rounded in front; rather coarsely asperate on anterior half, asperities confused; anterior margin armed by about a dozen low teeth; posterior half shining, coarsely, closely, deeply punctured.

Vestiture hairlike, moderately abundant except glabrous at center of disc.

Elytra 1.3 times as long as wide, 1.2 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae feebly if at all impressed, punctures close, moderately large, deep; interstriae slightly wider than striae, shining, punctures close, almost as large and as deep as those of striae. Declivity convex, steep; all punctures smaller than on disc, confused lateral to striae 2. Vestiture rather abundant, consisting of erect, short, strial hair and slightly longer interstrial hair; not conspicuously longer on declivity.

Male.-Similar to female except frons convex, reticulate, obscurely punctured, with sparse, inconspicuous, fine hair; elytral vestiture coarser and evidently more abundant.

Distribution. - Costa Rica.
COSTA RICA: San Ignacio de Acosta, San José, 5-VII$63,1100 \mathrm{~m}$, No. 29, fence post, S. L. Wood.

Biology.- This species was taken from phloem tissues of a recently cut fence post. From one to three females were associated with each male in star-shaped gallery systems; only the nuptial chamber reached the cambium. Larvae were not present.

Notes. - The above treatment was based on the type series of 10 specimens.

## 60. Scolytodes ingavorus Wood

Seolytodes ingatorus Wood, 1967, Great Basin Nat. 27:126 (Holotype, female; Los Corchos, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is rather closely related to ficivorus Wood, but it may be distinguished by the pubescent elytra, by the deeper punctures on the pronotal disc and, in the female, by the much more densely pubescens frons that lacks a shining glabrous area at the center.

Female.- Length $1.3-1.7 \mathrm{~mm}, 2.3$ times as long as wide; color yellowish brown, with anterior half of pronotum darker.

Frons flattened from upper level of eyes to somewhat elevated epistoma, with a pair of submarginal, low, longitudinal carinae (or elevations; obscured by vestiture) extending dorsad from epistomal margin, its upper limits obscured by vestiture; surface smooth and shining with fine punctures below, becoming finely granulate and obscurely punctured in
central area above; vestiture consisting of abundant, long, coarse, subplumose setae above upper level of eyes, continuing on lateral areas to epistomal margin as somewhat shorter setae, central area bearing shorter, fine, moderately abundant, hairlike setae.

Pronotum 1.1 times as long as wide; sides almost straight and parallel on slightly less than basal two-thirds, rather broadly rounded in front; summit just in front of middle, anterior area rather coarsely asperate; anterior margin armed by an almost continuous ridge; posterior areas reticulate, punctures coarse, deep, close, separated from one another by less than half diameter of a puncture; scanty hairlike setae confined to sides and asperate area.

Elytra 1.3 times as long as wide, 1.2 times as long as pronotum; sides almost straight (feebly arcuate), and parallel on slightly less than basal two-thirds, broadly rounded behind; striae not impressed, punctures coarse, distinctly but shallowly impressed; interstriae slightly wider than striae, punctures uniseriate, almost identical to those of striae. Declivity steep, convex; all punctures reduced, in rows; surface shining. Vestiture consisting of fine, short, erect, strial and interstrial hair, and longer interstrial hair on declivity.

Male. - Similar to female except frons broadly convex, transversely impressed just above epistoma; short vestiture on declivity stout, almost scalelike.

Distribution.- Nayarit.
MEXICO: Nayarit: Los Corchos, $10-\mathrm{VII}-65,10 \mathrm{~m}$, No. 211. Inga, S. L. Wood.

Biology.- This species infested phloem tissues in small, unthrifty branches of its living host.

Notes.- The above treatment was based on the type series of 45 specimens.

## 61. Scolytodes proximus Wood

Seolytodes proximus Wood. 1967, Great Basin Nat. 27:127 (Holotype, female; El Hato del Volcán, Chiriquí, Panama; Wood Coll.)
Diagnosis.- This species is rather closely related to tenuis Wood, but it may be distinguished by the very minute, obscure punctures on the pronotal disc, by the finer, shallower, elytral punctures, by the finer elytral
vestiture, and by the less abundant vestiture on the female frons.

Female.- Length $1.7-1.9 \mathrm{~mm}, 2.8$ times as long as wide; color dark brown.

Frons narrowly planoconcave from below upper level of eves to epistoma; surface reticulate, obscurely punctured; vestiture scanty, consisting of fine, rather sparse, long hair uniformly distributed from upper level of eyes to epistoma.

Pronotum 1.1 times as long as wide; widest slightly in front of middle, sides feebly constricted on posterior half, rather broadly rounded in front; summit indefinite, about one-third length from anterior margin; surface reticulate, minutely, sparsely punctured, anterior third finely asperate; anterior margin armed by a series of low, indefinite teeth. Glabrous except a few setae in asperate area.

Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on slightly more than basal twothirds, rather narrowly rounded behind; striae not impressed, punctures rather fine, shallow, obscure; interstriae as wide as striae, somewhat irregular, subshining, punctures fine, uniseriate, obscure. Declivity convex, steep; punctures obscure, about as on disc. Vestiture consisting of minute, recumbent, strial and interstrial hair, and sparse rows of longer, erect interstrial hair, each about as long as distance between rows.

Distribution.- Panama.
PaNama: El Hato del Volcán, Chiriquí, 11-1-64, 500 m, No. 390, Clusia, S. L. Wood.

Biology.- This species infested phloem tissues in unthrifty twigs of the living host tree.

Notes.- The above treatment was based on the type series of 33 specimens.

## 62. Scolytodes tenuis (Wood)

Hexacolus tcnuis Wood, 1961, Great Basin Nat. 21:99 (Holotype, female; 19 km SE Matamoros, Puebla, Mexico; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species is distinguished from micidus Wood by characters included in the above key.

Female.- Length $1.0-1.4 \mathrm{~mm}, 2.7-3.0$ times as long as wide; color very dark brown, almost black.

Frons flattened on a rather narrow area from epistomal margin to a point below upper level of eyes; flattened area finely punctured, pubescent, surface largely obscured by moderately abundant, long, yellow hair, longer and more dense on lateral and upper margins; only a few setae arise above upper level of eyes.

Pronotum 1.2-1.3 times as long as wide; sides straight and almost parallel on basal two-thirds, rather broadly rounded in front; anterior margin serrate, not a continuous costa; anterior third declivous and asperate, asperities decreasing in size posteriorly to well behind middle; surface subreticulate, shining, punctures coarse, deep, rather close. A few setae in anterior area.

Elytra 1.4-1.8 times as long as wide, 1.4-1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, then gently converging, broadly rounded behind; striae not impressed, punctures small, shallow, rather close; interstriae twice as wide as striae, almost smooth, shining, punctures fine, shallow, uniseriate. Declivity convex, rather steep; strial and interstrial punctures fine, subequal in size, in rows, striae 1 feebly impressed. Vestiture of strial and interstrial ground cover of fine, short, suberect hair arising from almost every puncture on disc and declivity; and interstrial, erect bristles on odd-numbered interstriae, spaced between rows and between bristles within a row by about one and one-half times length of a bristle.

Male. - Similar to female except frons convex, slightly flattened on lower third, reticulate, rather coarsely punctured, pubescence inconspicuous; body stouter, about 2.3 times as long as wide.

Distribution.- Jalisco to Honduras.
MEXICO: Jalisco: 8 km S La Huerta, 1-VII-65, 500 m , No. 168, Ficus. Morelos: Cuernavaca, 18-XII-44, Ficus petiolaris, N. L. H. Krauss. Puebla: 20 km SE Izúcar de Matamoros, 3-VII-53, I 200 m , Ficus. GUATEMALA: Palín, Esquintla, 19-V-64, 300 m , No. 683, Ficus; Volcán Pacaya, I-VI-64, I 300 m , No. 692, Ficus. HONDURAS: Zamorano, Morazán, 18-IV-64, 700 m , No. 558, Ficus glabrata. All by me, except as noted.

Hosts.-Ficus spp.
Biology.- This species breeds in unthrifty twigs of living trees and, less commonly, in cut branches.

Notes.- The above treatment was based on the type series of 9 specimens and on 92 other specimens.

## 63. Scolytodes micidus Wood

Scolytodes micidus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):17 (Holotype, female; 7 km N Totolapan, Oaxaca, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from tenuis Wood by the closely set bristles on all interstriae, by the finer interstrial punctures, and by the glabrous central area on the female frons.

Female.- Length $1.2-1.4 \mathrm{~mm}, 2.7-2.9$ times as long as wide; color almost black.

Frons flattened from epistoma to upper level of eyes, median third on lower half smooth, shining, slightly elevated, remaining area coarsely, closely, deeply punctured; punctured area bearing a tuft of long, yellow hair.

Pronotum 1.2 times as long as wide; sides rather strongly constricted on basal half, otherwise as in tenuis except posterior area smooth, shining (feebly reticulate in a few specimens).

Elytra 1.8 times as long as wide; outline and sculpture as in tenuis. Vestiture consisting of fine, short strial hair and long, erect interstrial bristles; each interstrial bristle slightly longer than distance between rows and between bristles within a row.

Male.-Similar to female except frons convex, deeply, narrowly, transversely impressed, surface coarsely, deeply punctured.

Distribution.- Oaxaca to Guatemala.
MEXICO: Oaxaca: 7 km N Totolapan, 20-VI-67, 1100 m, No. 68 Ficus, S. L. Wood. GUATEMALA: Palín, Esquintla, 19-V-64, 300 m , No. 683, Ficus, S. L. Wood.

Host. - Ficus spp.
Biology.- Specimens were taken from unthrifty twigs of living trees.

Notes. - The above treatment was based on the type series of 31 specimens.

## 64. Scolytodes exiguus Wood

Scolytodes exiguus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):22 (Holotype, male; San Isidro del General, San José, Costa Rica; Wood Coll.)
Diagnosis.- By definition this species should be placed in the subgenus Hexacolus due to the pronotal asperities and absence of
punctures toward the anterior margin of the pronotum; however, it almost certainly is more closely related to species here placed in the subgenus Scolytodes (s. str.). Its uniformly arched pronotum, pronotal sculpture, elevated declivital interstriae 9 , and other characters serve to distinguish it.

Male.- Length $1.2-1.3 \mathrm{~mm}, 2.0$ times as long as wide; color very dark brown.

Frons convex, becoming somewhat flattened toward epistoma; surface shining, with small, sparse punctures above, more closely punctured below except on shining lateral margins below level of antennal insertion; vestiture very sparse except along epistomal margin.

Pronotum 1.0 times as long as wide; widest at base, sides feebly arcuate, converging anteriorly on basal two-thirds, rather broadly rounded in front; dorsal profile arched from base, but more strongly declivous on anterior third; finely asperate on anterior third, punctures intermixed with asperities to anterior tenth but evidently not attaining anterior margin; posterior area shining, with a very indistinct suggestion of reticulation and a few minute points, punctures rather coarse, close, deep, separated by distances about equal to their diameters; vestiture consisting of a few bristles in asperate area.

Elytra 1.2 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal half, then increasingly arcuate to rather narrowly rounded posterior margin; basal margins marked by a fine raised line; striae not impressed, punctures rather large, moderately deep; interstriae about as wide as striae, shining, almost smooth, punctures fine, shallow, uniseriate. Declivity convex, moderately steep; striae moderately to weakly impressed, punctures somewhat smaller than on disc, deep; interstriae 1 weakly elevated, 2 and 3 weakly convex, punctures about as on disc. Vestiture consisting of erect, apically flattened, interstrial bristles of moderate length, abraded on disc of type, but present on both disc and declivity of paratype.

Distribution.- Costa Rica.
COSTA RICA: San Isidro del General, San José, 5-XII-63, 1000 m , No. 278, Ficus, S. L. Wood.

Biology.- Unthrifty, green twigs of a living, native, fig tree were selected for attack.

Notes.- The above treatment was based on the type series of two male specimens.

## 65. Scolytodes pumilus Wood

Scolytodes pumilus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):23 (Holotype, female: Volcán Poas, Heredia, Costa Rica; Wood Coll.)
Diagnosis.- This species is allied to obscurus Wood, but it may be distinguished by the coarser strial and interstrial punctures, and by the sparse vestiture on the female frons.

Female.- Length 1.4-1.6 mm, 2.5 times as long as wide; color rather dark brown.

Frons rather narrowly flattened from just below upper level of eyes to epistoma; surface finely reticulate-granulate, moderately large punctures rather close, only slightly less dense at center; vestiture very fine, moderately dense, rather long.

Pronotum 1.0 times as long as wide; widest at base, converging slightly on basal twothirds, rather broadly rounded in front; dorsal profile arched from base, more strongly declivous on anterior third; asperities small, confused; posterior area reticulate, with very tine, sparse punctures. Glabrous.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures rather coarse, deep; interstriae almost smooth, about as wide as striae, punctures indefinite or absent on basal half, small, uniseriate, becoming distinct toward declivity. Declivity rather steep, narrowly convex, striae I weakly impressed; strial punctures smaller than on disc, deep; interstriae shining, punctures rather small, deep. Glabrous.

Male. - Similar to female except frons rather weakly convex, surface almost smooth and shining, reticulation obscurely indicated, punctures minute, obscure; striae somewhat confused on basal fourth, interstrial punctures more evident on 1 and 2 .

Distribution.- Costa Rica.
COSTA RICA: Volcán Poas. Heredia, 19-VIIl-66, 2000 m , No. $97 ; 10 \mathrm{~km}$ SE Cartago, Cartago, 3-VII-63, 1800 m . No. 18, Drimys granadensis, 14-VII-63, No. 43 , Sapium thelocarpum, 24-IX-63, No. 204, Miconia globuliflora; all by me.

Hosts.- Drimys granadensis, Miconia globuliflora, and Sapium thelocarpum.

Biology.- This monogamous species attacked cut or unthrifty small branches of its hosts. The egg chamber was longitudinally elongate. Larval mines were short and irregular.

Notes.- The above treatment was based on the type series of 50 specimens.

## 66. Scolytodes obscurus (Wood)

Hexacolus obscurus Wood, 1961, Great Basin Nat. 21:100 (Holotype, female; 5 km SW Martinez de la Torre, Veracruz, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from nanellus Wood by characters summarized in the above key.

Female.- Length $1.0-1.3 \mathrm{~mm}, 2.4$ times as long as wide; color brown.

Frons flattened from epistoma to upper level of eyes, central fourth on lower half smooth, shining, remaining area rather coarsely, closely, shallowly punctured; vestiture of long, rather abundant, yellow hair arising on punctured area, few setae above upper level of eyes.

Pronotum 1.03 times as long as wide; widest at base, sides feebly arcuate, converging slightly on basal two-thirds, rather narrowly rounded in front; finely asperate on anterior half; posterior half deeply reticulate, shining, punctures minute, shallow. Glabrous.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures small, shallow, rather indefinite; interstriae about twice as wide as striae, surface somewhat irregular, shining, punctures fine, shallow. Declivity convex, rather steep; sculpture as on disc. Glabrous.

Male.- Similar to female except frons evenly convex; surface reticulate, punctures minute, vestiture inconspicuous.

Distribution.- Veracruz.
MEXICO: Veracruz: 5 km SW Martínez de la Torre. 26-VI-53, 3(9) m, S. L. Wood.

Biology.- The type series was taken from a large herbaceous shrub in radiate parental galleries in the phloem tissues.

Notes.- The above treatment was based on the type series of 46 specimens and on 21 other specimens.

## 67. Scolytodes nanellus Wood

Scolytodes nancllus Wood, 1967, Great Basin Nat. 27:124 (Holotype, female; Barro Colorado Island, Canal Zone, Panama: Wood Coll.)
Diagnosis.- This species is somewhat allied to pumilus Wood, but it is much smaller, much less coarsely punctured, and the female frons is armed by a pair of submarginal, longitudinal carinae below and by a brush of long hair above upper level of eyes.

Female.- Length 1.0 mm , male 0.9 mm , 2.4 times as long as wide; color medium brown.

Frons flattened from upper level of eyes to epistoma, with submarginal, low carina extending from epistoma almost to upper level of eyes; surface subshining, very finely and closely punctured; vestiture consisting of rather abundant, coarse, subplumose setae confined to area near or above upper level of eyes, some of setae almost reaching epistomal margin.

Pronotum 1.1 times as long as wide; widest just behind middle, sides feebly arcuate, rather broadly rounded in front; summit distinctly in front of middle, very finely asperate in front, posterior area rather coarsely reticulate, punctures rather fine, not deep. Glabrous.

Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, rather narrowly rounded behind; striae 1 weakly, others not impressed, punctures small, not deep; interstriae slightly wider than striae, shining, almost smooth, punctures fine, not always clearly impressed. Declivity convex, rather steep; all punctures somewhat reduced. Vestiture consisting of a few scattered bristles on or near declivity.

Male.-Similar to female except frons convex, with a slight transverse impression just above epistoma, surface subreticulate, minute punctures obscure, vestiture reduced, confined to epistomal area.

## Distribution.- Panama.

PANAMA: Barro Colorado Island, Canal Zone, 27 -XII-63, 70 m , No. 347, tree branch, S. L. Wood.

Biology.- This species infested phloem tissues in a small branch.

Notes. - The above treatment was based on the type series of four specimens.

## Scolytodes trispinosus Eggers

Scolytodes trispinosus Eggers, 1934, Ent. Blätt. 30:80 (Holotype, female; Amatán; U.S. Nat. Mus.) Scolytodes elongatus Schedl, 1935, Stylops 4:273 (Holotype, female?: Brazil; Schedl Coll.); Wood, 1979, Great Basin Nat. 39:136. Synonymy
The female holotype of Scolytodes trispinosus Eggers was compared directly to my specimen identified by Schedl as Scolytodes elongatus Schedl (from Nova Teutonia, Brazil, 4-V-50, F. Plaumann) and compared by me to the holotype of elongatus. Two of the
three known specimens of this species are from Brazil. The pin bearing the type of trispinosus has the printed label "Amatán" and a handwritten label in ink, "Mexico." Because this species resembles several South American species but none from Central America, because it is not definitely known from any locality outside of South America, and because the label "Mexico" was subsequently added to the pin of the type, I have removed this species from the Mexican fauna and added it to that of South America.

## Tribe MICRACINI

Micracides LeConte, 1876, Trans. Amer. Philos. Soc. 15:346
Hylocuridae Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége, Ser. 2, 8:306 (in part)

Anatomical features.- The Micracini are characterized by the 6 -segmented antennal funicle, by the moderately to very strongly procurved sutures of the antennal club, by the moderately separated anterior coxae, by the distinctive protibia, which usually has the margins parallel and all or most of the socketed teeth on the distal margin, by the rounded margins of the pronotum, and by the somewhat distinctive, subplumose vestiture.

Brological features.- With very few exceptions, the members of this tribe breed in small branches and twigs of hardwood trees and shrubs. A majority of them occurs in desert and semidesert areas. The Pseudothysanoes, Stenocleptus, and Phloeocleptus are primarily phloeophagous and monogamous; Thysanoes, Micracis, and Hylocurus are xylophagous and bigamous. The Micracisella are pith boring and monogamous. Details of their life cycle are poorly known except that development of most species apparently is very slow.

Taxonomy.- Most of the species in this group breed in small twigs and branches of trees and shrubs having little or no economic importance; consequently, they are generally regarded as scientific curiosities of minor significance. For this reason their biology, distribution, and classification are inadequately known. The tribe occurs in North and South America and in Africa. Almost every American genus has its very similar, but distinct, counterpart in the African fauna.

## Genus PSEUDOTHYSANOES Blackman

[^9]species: Cryptocleptes dislocatus Blackman, monobasic); Wood, 1971, Great Basin Nat. 31:141. Synonymy
Chalcohyus Blackman, 1943, Proc. U.S. Nat. Mus. 93(3165);363 (Type-species: Chalcohyus securigerus Blackman, monobasic); Wood, 1971, Great Basin Nat. 31:141. Synonymy
Aphanocleptus Wood, 1960, Great Basin Nat. 20:63
(Type-species: Aphanocleptus coniferae Wood, monobasic) (Retained as a subgenus)
Cryptulocleptus Wood. 1962. Great Basin Nat. 22:76 (Replacement name for Cryptocleptes Blackman); Wood, 1971, Great Basin Nat. 31:141. Synonymy
Diagnosis.- This genus is closely related to Tysanoes LeConte, but it may be distinguished by the pronotum being as wide or wider than long, by the more prominent pronotal summit, by the more slender protibiae, which are apically tapered or obliquely truncate, with the terminal mucro widened or bifurcate in females of most species, and by the (usually) phloeophagous habit.

Description.- Length $0.7-2.0 \mathrm{~mm}$, 2.0-2.8 times as long as wide, males often shorter and stouter than females; color yellowish brown to black, vestiture usually pale.

Frons usually sexually dimorphic, varying from convex to deeply excavated in either sex, usually more strongly impressed in female. Antennal scape short and broadly expanded (subgenus Aphanocleptus) or elongate and slender (subgenus Pseudothysanoes); funicle 6 -segmented; club small to large, broad to very slender, with or without sutures. Pronotum as wide or wider than long, asperate on anterior half, summit usually well developed, anterior margin usually serrate in male, rarely armed in female. Elytra usually sexually dimorphic, female sculpture simple, conservative, in some groups with little interspecific variability; male elytra extremely variable; elytral apex rounded except moderately mucronate in one species.

Distribution.- Southeastern Canada to Brazil; 61 species occur north of Panama, and 8 from the Caribbean area and South America.

Biology.-All observed species were either monogamous or bigamous and constructed biramous parental galleries in the phloem or cambium tissues, except for the xylophagous heliura group and mucronatus Wood, and those species which bore in dying Yucca leaves. Larval mines usually wander indiscriminately and are moderately long. A majority of the known species inhabit arid or semiarid country, where they infest desert shrubs. A few species also occur in very wet, tropical forests.

Notes.- The diversity of species in this group is great. Several species groups were previously named or treated as distinct genera, but the recently named species clearly demonstrate that sutures of the antennal club and characters of the funicle are not reliable characters for separating species groups within the genus. These species groups are being modified in parallel fashion simultaneously along several different lines of evolutionary development not sufficiently distinct to constitute genera. The bifurcate terminal mucro of the female protibia also is being developed or suppressed along several different evolutionary lines and should be used in the classification of species with great caution.

## Key to the Species of Pseudothysanoes

1. Antennal scape short, strongly flattened, commonly as wide or wider than long
in both sexes, little if any longer than pedicel; antennal club rather small,
widest through basal half, sutures, when present, straight or moderately
procurved; subgenus Aphanocleptus ........................................................................... 2

Antennal scape elongate, slender, club-shaped, at least twice as long as pedicel,
club variable, with or without sutures; subgenus Pscudothysanoes ......................... 13
2(1). Interstriae 3 on declivity not at all elevated, declivity more narrowly convex .......... 3

- Interstriae 3 on declivity distinctly (weakly in female of sedulus and

3(2). Frons in both sexes (or in female only) deeply, broadly, concavely excavated
from eye to eye, from epistoma to well above upper level of eyes; mandibles
either normal or modified ............................................................................. 4a

- Frons feebly if at all impressed in either sex; mandibles normal .................................. 5
$4 \mathrm{a}(3)$. Frons very extensively impressed, upper margin of concavity slightly projecting orad on median fourth, glabrous; mandibles near middle armed by a strongly developed, transverse ridge; Oaxaca; 1.4-1.6 mm ........ 3. excavatus (Wood)
Female frons less extensively impressed, upper margin of concavity abrupt, not
projecting, bearing a row of scales; male frons flat to moderately convex,
mandibles normal ................................................................................................. bb
$4 \mathrm{~b}(4 \mathrm{a})$. Excavated area on female frons glabrous, impunctate, rugose-reticulate; pronotal dise rugose-reticulate; Chiapas; $1.2-1.4 \mathrm{~mm}$ 1. recavus Wood
- Excavated area on female frons with short, stout setae uniformly distributed, surface smooth, shining, sparsely punctured; pronotal dise smooth, shining; Texas; Prosopis; 1.2-1.4 mm

2. turnbowi Wood
$5(3)$ Posterior area of pronotal dise reticulate to rugulose, punctures granulate; discal interstriae usually with uniseriate rows of granules; Nuevo León to Veracruz; Quercus; 1.2-1.5 mm 4. querneus Wood

- Posterior area of pronotal dise smooth, shining, punctured; discal interstriae devoid of granules

| $6(5)$. | Larger; pronotal punctures on disc coarse, deep, close; strial punctures coarse, as wide as interstriae; Chihuahua to Nuevo León; Picea, Pseudotsuga; 1.3-1.7 mm <br> 5. coniferae (Wood) |
| :---: | :---: |
| - | Smaller; pronotal punctures minute, widely spaced; strial punctures fine, less than half as wide as interstriae; $0.8-1.4 \mathrm{~mm}$ $\qquad$ 7 |
| 7(6). | Male body stout, 2.0 (female 2.3) times as long as wide; interstrial scales of male almost as long as distance between scales within a row, about threefourths as long as distance between rows; male declivity broadly convex, surface with abundant, minute, points; female frons broadly subconcave; Oaxaca; Gossypium; 1.0-1.4 mm $\qquad$ 6. obesus (Wood) |
|  | Male body slender, 2.4 (female 2.8) times as long as wide; interstrial scales of male spaced within a row and between rows by two or more times length of a scale; male declivity narrowly convex, almost smooth; female frons flattened on lower half; Durango to Oaxaca; Quercus; 0.8-1.5 mm (see also 8. concentralis Wood) $\qquad$ 7. quercinus (Wood) |
| $8(2)$. | Smaller; strial punctures minute, discal interstriae three times as wide as striae; interstriae 3 in male strongly elevated on upper two-thirds of declivity, ending abruptly below, its summit not serrate; Sinaloa; 1.0-1.2 mm .......... 9. thomasi Wood |
| - | Larger; interstriae and striae about equal in width; elevation on interstriae 3 extending to junction with 9 $\qquad$ 9 |
| 9(8) | Inter |
| - | Interstriae 3 and 9 moderately to rather strongly elevated ................................... 11 |
| 10(9). | Strial punctures comparatively small, spaced within a row by distances greater than diameter of a puncture; interstrial scales slender, about three to five times as long as wide; body color brown; Arizona to Chihuahua; Quercus; 0.9-1.3 mm $\qquad$ 10. brunneus Wood |
| - | Strial punctures rather coarse, spaced within a row by distances equal to half diameter of a puncture; interstrial scales broad, less than three times as long as wide; body color black; Arizona to New Mexico; Quercus; 1.4-1.7 mm ............. |

11. sedulus Blackman

11(9). Small, slender, 2.7 times as long as wide; male declivital interstriae 3 exceedingly strongly, narrowly elevated and continued to apex, elevation more than twice as high as wide, height almost equal to width of interstriae 1 and 2 combined, its summit coarsely serrate; interstriae 4-9 on declivity each with two to six rather coarse tubercles; female declivital interstriae 1 and 9 moderately elevated, elevation not as high as wide; female frons narrowly, shallowly concave near center; Jalisco; Struthanthus; $1.0-1.3 \mathrm{~mm}$
12. vallatus Wood

- Larger, stouter species with declivital interstriae only moderately elevated; usually in Quercus12

12(11). Strial punctures coarse, interstriae narrower than striae; vestiture behind pronotal summit uniformly slender; Sinaloa and Durango to Michoacán; Quercus; $1.3-1.6 \mathrm{~mm}$ (see also 13 . securus Wood) 14. quercicolens Wood

- $\quad$ Strial punctures smaller, interstriae as wide as striae; vestiture behind pronotal summit largely scalelike, intermixed with slender setae; New York to North Carolina; Quercus, etc.; 1.1-1.4 mm

15. lecontei Blackman

13(1). Antennal club moderately large, with straight sutures clearly indicated; terminal mucro on anterior tibia unmodified, slender in both sexes; male elytral declivity convex, unarmed by spines or marginal or other elevated ridges, ornamented by rows of interstrial scales; hosts Phoradendron

| - | Antennal club often small, slender, sutures moderately to strongly procurved if visible, obsolete in many species; terminal mucro on anterior tibia normal in male, in female usually conspicuously widened or bifurcate; male elytral declivity commonly armed by spines or elevated ridges $\qquad$ 27 |
| :---: | :---: |
| 14(13). | Female frons rather strongly convex above level of antennal insertion, not ornamented by long hair at vertex; male variable, but frons usually more strongly convex $\qquad$ |
| - | Female frons rather deeply, broadly concave (shallowly concave in graniticus) from epistoma to vertex, upper margins on or near vertex ornamented by a tuft of long hair; male frons shallowly concave almost to upper level of eyes ................. 23 |
| 15(14). | Male declivity strongly convex, commencing well behind middle, declivital striae not impressed, punctures moderately small to very fine, interstrial bristles less radically modified $\qquad$ |
|  | Male declivity broadly convex, commencing in front of middle, striae impressed, punctures coarse, deep, interstrial bristles very long. $\qquad$ 22 |
| 16(15). | Strial punctures on male declivity little if any smaller than on disc; male discal interstrial gramules usually continued to elytral base, interstrial scales usually shorter $\qquad$ |
| - | Strial punctures on male declivity minute or entirely obsolete; interstrial granules on disc absent; interstrial scales longer $\qquad$ 20 |
| 17(16). | Interstrial scales on male declivity two to three times as long as wide, each scale distinctly shorter than distance between scales within a row or between rows $\qquad$ |
| - | Interstrial scales on male declivity at least five times as long as wide, each at least one and one-third times as long as distance between scales within a row or between rows $\qquad$ 19 |
| 18(17). | Interstriae on male disc finely, uniseriately punctured; Phoradendron; Oaxaca; <br> $1.1-1.4 \mathrm{~mm}$ $\qquad$ 16. furvescens Wood |
| - | Interstriae on male disc uniseriately granulate to base; Honduras to Costa Rica; <br> Phoradendron; 1.1-1.4 mm $\qquad$ 17. furvus Wood |
| 19(17). | Male elytral declivity shorter, steeper, more strongly convex, confined to posterior third, interstrial scales each about five times as long as wide, each scale about one and one-third times as long as distance between scales in a row or between rows; Jalisco; Phoradendron; 1.0-1.4 mm $\qquad$ 18. furvatus Wood |
| - | Male elytral declivity more gradual, almost reaching middle of elytra, more broadly convex, interstrial scales each about six to eight times as long as wide, at least twice as long as distance between scales in a row or between rows; California and Arizona to Chihuahua and Texas; Phoradendron; $1.0-1.5 \mathrm{~mm}$ (see also 19a. leechi Wood) $\qquad$ 19b. phoradendri Blackman |
| 20(16). | Male declivity with fine, uniseriate granules on all interstriae, strial punctures fine, distinct, interstrial scales more closely, regularly spaced on lower half of declivity; Jalisco; Phoradendron; 1.3-1.5 mm ................................ 20. funereus Wood |
| - | Male declivity devoid of strial and interstrial punctures and granules on central area of lower half, interstrial scales usually absent from this area $\qquad$ 21 |
| 21(20). | Strial punctures on disc rather coarse, about as wide as interstriae; interstriae 3 on male declivity bearing three or four moderately coarse granules; Durango to Coahuila; Phoradendron; 1.4-1.8 mm ........................................ 21. funebris Wood |

- Strial punctures on disc very small, scarcely half as wide as an interstriae; male declivity devoid of granules, bearing a large, conspicuous, shining bulla on lower half covering interstriae 2 and 3; Oaxaca; Phoradendron; $1.5-2.0 \mathrm{~mm}$

22. bullatus Wood

22(15). Male elytral declivity occupying slightly more than posterior half of elytra, interstriae 8 at base of declivity bearing a double row of scales; scales on male elytral declivity about twice as long as distance between rows, each scale with its sides parallel almost to its apex; Nayarit; Phoradendron; $1.4-1.7 \mathrm{~mm}$
23. viscivorus Wood

- Male declivity occupying posterior two-thirds of elytra, scales at base of declivity on interstriae 8 uniseriate; declivital scales of male three or more times as long as distance between rows, each widest at base, tapering very gradually to blunt apex; Oaxaca; Phoradendron; 1.3-1.6 mm

24. amassius Wood

23(14). Interstrial scales on disc longer, slender, each more than four times as long as wide; female frons with a dense tuft of very long hair on vertex, tips of some hairs reaching epistomal margin; scales on male declivity more widely spaced within a row than between rows, each scale about eight times as long as wide; Puebla; Phoradendron; $1.4-1.7 \mathrm{~mm} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ~ 25 . ~ p e n i c u l u s ~ W o o d ~$

- Interstrial scales on disc broad, less than three times as long as wide; hair in tuft on female vertex not more than half long enough to reach epistomal margin, less abundant; scales on male declivity much more closely spaced within a row than between rows24

24(23). Female frons shallowly impressed from epistoma to vertex, tuft of hair at upper limits of impression very short, moderately abundant; (poorly developed in tumidulus); declivital interstriae in male uniseriately, rather coarsely granulate (except tumidulus), scales on lower half of interstriae 1 slightly smaller25

- Female frons rather deeply concave, tuft of hair on vertex much longer, reaching almost half distance to epistomal margin; declivital interstriae in male feebly if at all granulate

25(24). Female frontal vestiture only slightly longer on vertex; female elytral scales small; male declivity obtusely subangulate at base, basal half impressed, an obscure bulla at middle, declivital face glabrous, interstriae with fine rounded granules; Queretaro; Phoradendron; 1.5-2.0 mm
26. tumidulus Wood

- Female vestiture on vertex distinctly longer and more abundant; male declivity convex, with rows of scales 26
$25 \mathrm{~b}(15 \mathrm{a})$. Female frontal impression ending at upper level of eyes, hair on vertex less abundant, yellowish, lower half of frons brightly shining, glabrous except for well-developed epistomal brush; female elytral scales four times as long as wide; Oaxaca; Phoradendron; 1.9-2.0 mm

27. graniticus Wood

- Female frontal impression deeper, extending above eyes, hair on vertex dense, white, lower half of frons sparsely pubescent, devoid of epistomal brush; female elytral scales short, about one to one and one-half times as long as wide; Hidalgo; Phoradendron; 1.6 mm

28. verticillus Wood

26(24). Male declivity confined to slightly more than posterior third of elytra; strial punctures fine, shallow; scales on male declivital interstriae similar throughout, each about three to four times as long as wide; tuft of hair on female vertex slightly longer; Tlaxcala to Oaxaca; Phoradendron; 1.3-1.8 mm

- Male declivity occupying more than posterior half of elytra; strial punctures rather coarse, rather shallow; scales on interstriae 1-3 on lower half of male declivity about half as long as those on remaining area; tuft of hair on female vertex slightly less dense, shorter; Honduras: Phoradendron: 1.3-1.7 mm

30. viscicolens Wood

27(13). Elytral apices clearly mucronate; general habitus much like Micracis, but tibiae and antennae clearly of Pseudothysanoes; color reddish brown; discal strial punctures small, shallow: declivital interstriae all uniseriately, coarsely granulate; xylophagous: Honduras; $1.2-1.4 \mathrm{~mm}$ 31. mucronatus (Wood)

- Elytral apices not at all mucronate 28

28(27). Male abdominal tergum 8 narrowly mucronate and projecting beyond elytral apices falsely resembling an elytral mucro; last visible female sternum narrowly projecting to form a mucro resembling that of male; female frons concave or flat

- Male tergum 8 and female sternum 5 normal, not mucronate .................................... 31

29(28). Female frons flattened, slender median groove on upper half; strial and interstrial punctures on declivity rather coarse, apparently confused; elytral vestiture of fine hair and slender bristles; Puebla; 1.2-1.4 mm ...... 32. cuspidis Wood

- Female frons concave; strial and interstrial punctures on declivity in rows: vestiture usially coarser 30
30(28). Strial punctures moderately large, rather deep, sharply impressed; male strial and interstrial declivital setae scalelike, those on interstriae twice as large. each about twice as long as wide, in female strial setae hairlike, interstrial scales each three to four times as long as wide; female frons deeply concave; Guatemala: 1.3-1.7 mm 33. subulatus (Wood)
- Strial punctures obscurely shallowly impressed, not clearly defined, evidently very small; male interstrial declivital scales small, three to four times as long as wide, strial setae hairlike, in female both strial and interstrial setae slender, almost hairlike; female frons less deeply concave; Panama; $1.5-1.8 \mathrm{~mm}$

34. spicatus (Wood)

31(28). Sutures of antennal club) commonly but not always clearly marked; pronotum commonly with a distinct constriction on anterior half and narrowly rounded in front; pronotal summit usually behind middle, usually narrow, often impressed on either side, posterior area tending to be more coarsely sculptured (pronotal characters do not fit heliura group); if antennal and pronotal characters doubtful, then male elytral declivity either armed on interstriae 2 and 4 by coarse spines or else a conspicuous partial or complete circumdeclivital ridge present32

- Sutures of antennal club obscure or entirely absent; pronotum broadly rounded in front, without a lateral constriction, summit at or anterior to middle, usually broad; male elytral declivity never armed by spines or ridges
32(31). Male elytral declivity convex, never armed by an elevated ridge or costa; pronotum constricted on anterior half, summit narrow, behind middle; if placement doubtful, then elytral scales very slender33
- Male elytral declivity with a sharply elevated lateral ridge that may continue from apex to suture at base of declivity, forming a complete circumdeclivital ridge; female slender, declivital ridge entirely absent, declivital scales short, broad, each about two to three times as long as wide; pronotal summit broad, in front of middle, posterior area smooth or very finely sculptured
33(32). Male elytral declivity unarmed by spines on any interstriae ..... 34
- Male elytral declivity armed by four or more long, slender, pointed spines ..... 43
34(33). Antennal club large (except hopkinsi), much longer and usually also wider than length of scape, two procurved sutures well developed ..... 35
- Antennal club small, slender, its length less than length of scape, entirely devoid of sutures ..... 40
35(34). Interstrial scales on declivity short, rather broad, separated within a row by more than twice length of a scale ..... 36
- Interstrial scales on declivity separated by distances equal to length of a scale (some male hopkinsi with a few scales more widely spaced) ..... 3736(35). Elytral scales very small, spaced within a row by distances equal to three timeslength of scale, between rows by more than twice length of a scale, each scaletwo to three times as long as wide; frons shallowly concave on lower two-thirds in both sexes; female scape with a conspicuous tuft of hair; Oaxaca;Psittacanthus; $1.4-1.7 \mathrm{~mm}$35. plumalis Wood
Male frons with a narrow, weak impression near center; male declivital scalesseparated within a row by distances equal to twice length of a scale, betweenrows by slightly less than twice length of a scale, each scale broad, less thantwice as long as wide; Jalisco; $1.2-1.3 \mathrm{~mm}$36. coracinus Wood

37(35). Interstrial scales on male declivity elongate, some three or more times as long as distance between rows, normal in female, each scale about three times as long as wide; frons almost flat in both sexes, a very feeble, small impression near center; Michoacán; Phoradendron; 1.3-1.6 mm 37. tenellus Wood

- Male interstrial declivital scales not longer than distance between rows, female scales three or more times as long as wide38

38(37). Frons flattened to weakly convex, devoid of any impression; interstrial scales on declivity 3 to 6 times as long as wide in male, 6 to 10 or more times in female; antennal club small, 1.6 (male) to 1.8 (female) times as long as wide; Durango; Yucca leaves; 1.1-1.3 mm
38. yuccavorus Wood

- Frons flattened to shallowly concave, with a large, strongly impressed, shining fovea within concave area; interstrial scales on declivity about three to four times as long as wide in male, four to five times as long as wide in female; antennal club 1.4 times as long as wide or less39

39(38). Discal interstriae uniseriately granulate, rather coarse in female; male interstrial scales about six times as long as wide; S California; Fremontia; 1.3-1.5 mm 39. hopkinsi Blackman

- Discal interstrial punctures not at all granulate in male, feebly granulate in female; male interstrial scales each about four times as long as wide; Michigan and Ontario to Kansas and Pennsylvania; Tilia; 1.3-1.6 mm

40(34). Antennal club not more than 1.5 times as long as wide, three times as wide as width of pedicel; male and female body form similar, slender41

- Antennal club small, slender, 2.0 times as long as wide, about twice as wide as
width of pedicel; body form sexually dimorphic, male very stout ..... 42

41(40). Discal interstrial vestiture of blunt, slender scales; declivital interstrial scales slightly shorter than distance between rows; frons transversely impressed at level of antennal insertion, with a distinctly impressed median fovea; Puebla; Arbutus; $1.0-1.3 \mathrm{~mm}$

|  | Discal interstrial vestiture of pointed, stout hair; declivital interstrial bristles distinctly longer than distance between rows; frons weakly convex; Panama; <br> $1.2-1.3 \mathrm{~mm}$ $\qquad$ 42. caritus (Wood) |
| :---: | :---: |
| 42 | Male discal interstriae devoid of granules; pronotal summit very narrow; Oaxaca; leguminous shrub; 0.8-1.2 mm $\qquad$ 43. crassinus Wood |
| - | Male discal interstriae uniseriately coarsely granulate; pronotal summit rather broad; Arizona; Yucca leaves; $0.8-1.2 \mathrm{~mm}$ $\qquad$ 44. frondicolens Wood |
|  | Male elytra with recurved spines on declivital interstriae 2, 3, 5, and 7 of about equal size, slightly longer than very broad scales; Chiapas; Acacia; $1.0-1.2 \mathrm{~mm}$ $\qquad$ 45. contrarius Wood |
| - | Male declivity with spines on either interstriae 2 or 3, spines directed caudad ....... 44 |
|  | Male declivity with major spines on interstriae 3; female frons at least partly concave; larger, darker, more coarsely sculptured species. $\qquad$ 45 |
| - | Male declivity with major spines on interstriae 2; female frons convex; smaller, lighter in color, more finely sculptured $\qquad$ 46 |
|  | Male declivital interstriae 3 armed by two coarse spines, 5 and 7 each with one smaller spine, 1 unarmed; female frons abruptly, rather deeply concave on median third; discal interstriae feebly if at all granulate; California; Sphaeralcea; $1.2-1.4 \mathrm{~mm}$ $\qquad$ 46. bartoni Bruck |
| - | Male interstriae 1,3 , and 5 each bearing one or more spines, those on 3 largest; female frons concave from eve to eye from epistoma to vertex; discal interstriae uniseriately, finely granulate; Florida; Tilia; 1.2-1.4 mm |
|  |  |
|  | Male elytral declivity normally convex, commencing well behind middle of elytra; spines on male interstriae 2 equal in length to little more than half width of interstriae 2 ; interstrial granules finer and scales slightly narrower in both sexes; Costa Rica; Acacia; 1.0-1.3 mm $\qquad$ 48. acacicolens Wood |
| - | Male elytral declivity rather strongly impressed on upper half, commencing in front of middle; spines on male interstriae 2 as long or longer than width of interstriae 2; interstrial granules slightly larger and scales broader in both sexes; <br> Oaxaca; 0.9-1.3 mm $\qquad$ 49. spinatus Wood |
| 47 | Male elytral declivity with elevated lateral ridge extending from apex to interstriae 9, ending near declivital base; strial punctures coarse, deep, interstriae about half as wide as striae in male; female frons shallowly impressed on lower half; Arizona; Quercus; 1.0-1.2 mm $\qquad$ 50. costatus Wood |
| - | Male elytral declivity completely encompassed by circular, elevated ridge extending from sutural apex along ventrolateral margin of declivity to suture at base of declivity; female frons more strongly impressed over greater area $\qquad$ 48 |
|  | Face of male declivity broadly, evenly convex, punctures coarse, confused; female frons shallowly concave, median fovea obscure if present $\qquad$ 49 |
|  | Face of male declivity more strongly impressed near ridge, more irregularly protruding toward interstriae 2, interstriae 2 bearing a series of four or more coarse bristles, strial punctures small, more or less in rows; female frons with median fovea very deeply impressed, strong concavity includes part or all of frons $\qquad$ 50 |
|  | Smaller, more slender; male circumdeclivital ridge feebly or not at all elevated near apex; female frons broadly concave from epistoma to vertex, a patch of fine, short pubescence on upper third; Colima; 0.9-1.1 mm $\qquad$ 51. vesculus Wood |

- Larger, stouter; male circumdeclivital ridge strongly elevated near apex, about twice as high as thick; female frons shallowly concave on lower half, devoid of pubescence; Texas; Condalia; 1.3-1.5 mm

52. heliura Wood

50(48). Impressed area immediately inside circumdeclivital ridge on male declivity poorly developed, central convex area occupying three-fourths of declivity, interstriae 2 usually not at all granulate at bases of bristles; female frons with strong, narrow, transverse impression at level of antennal insertion connected to deep, narrow, median impression; Arizona to Chihuahua; Ceanothus; $1.1-1.3 \mathrm{~mm}$
53. spinura Wood

- Impressed area near inner margins of male declivity broad, strongly developed, central, strongly convex area occupying half of declivity, interstriae 2 granulate at base of bristles; female frons deeply concave from epistoma to vertex; Colima; $1.0-1.2 \mathrm{~mm}$

54. mancus Wood

51(31). Interstrial setae on female declivity very slender, bristlelike, those on male declivity four or more times as long as wide; female frons largely convex

- Interstrial setae on both male and female declivity about two to six times as
long as wide; female frons broadly, shallowly impressed ...................................... 53

52(51). Female frons convex above, somewhat flattened on lower third; elytral punctures minute, very obscure; male declivital scales about six times as long as wide; Puebla; Yucca leaves; $0.8-1.2 \mathrm{~mm}$
55. yuccae (Wood)

- Female frons convex, with a small, narrow, shallow, median impression on lower half; elytral punctures minute, distinct; male declivital scales about four times as long as wide; Оaxaca; $0.7-1.0 \mathrm{~mm}$

56. minulus (Wood)

53(51). Male strial punctures on disc coarse, deeply impressed, striae much wider than
interstriae; female frons broadly, shallowly, evenly concave .................................. 54

- Male strial punctures smaller, not as deep, interstriae distinctly wider than striae; female frons usually less extensively, more abruptly impressed at least on upper half of impressed area
54(53). Male discal interstriae smooth, with minute, uniseriate punctures; male elytra more slender, 1.7 times as long as wide; female frons shining, glabrous; S Texas to Tamaulipas; Mimosa, Acacia; 0.9-1.1 mm

57. acaciae (Blackman)

- Male interstrial punctures on posterior half of disc rather coarsely, uniseriately granulate; male elytra stouter, 1.4 times as long as wide; female frons with rather dense, subpilose hair on upper half of concavity; Oaxaca; $0.8-1.0 \mathrm{~mm} \ldots$. 58. subpilosus (Wood)

55(53). Male declivity with strial punctures moderately coarse on upper half, smaller but distinct below, similar differences in females but much more difficult to detect

- Male declivity with striae obsolete or nearly so, punctures confused if distinct
59

56(55). Male declivity with strial punctures very close, separated by much less than diameter of a puncture, deeply impressed, interstrial punctures very close, moderately coarse; female frons rather deeply concave57

Male declivital striae not impressed, strial and interstrial punctures rather
widely spaced, interstrial punctures much smaller than those of striae .................... 58
57(56). Male declivital striae apparently impressed, interstriae weakly elevated, very indistinctly granulate; female frons more extensively excavated to well above upper level of eyes; Оaxaca; leguminous tree; 1.1-1.4 mm 59. acares (Wood)

- Male declivity with striae not impressed, interstriae not elevated, smooth; female frontal excavation ending at upper level of eyes; Oaxaca; leguminous shrub; $1.0-1.4 \mathrm{~mm}$ 60. mirus (Wood)

58(56). Male strial punctures on disc rather deep, interstriae on disc not all granulate; male anterior margin of pronotum armed by eight teeth; pronotal dise more reticulate-granulate; female frons shallowly, broadly concave almost from eye to eye, lateral margins obtusely angled; Michoacán; Acacia; 1.0-1.4 mm
61. aquilus (Wood)

- Male strial punctures on disc of equal size but shallow, interstrial punctures on declivity distinctly, feebly granulate: male anterior margin of pronotum armed by four teeth; pronotal dise more shining; female frons concavely impressed on less than median half, lateral margins indefinite, rounded; West Virginia to Florida and Louisiana; Carya; $1.0-1.3 \mathrm{~mm}$ (see also 63. perseae Wood)

62. dislocatus (Blackman)

59(55). Sutures of antennal club clearly developed and marked by setae; male strial punctures on disc larger, interstrial scales on declivity about four times as long as wide; larger; Arizona; $1.0-1.4 \mathrm{~mm}$
64. huachucae Blackman

Sutures on antennal club obsolete; male strial punctures on disc smaller, interstrial scales on declivity wider, about twice as long as wide; smaller species ... 60
$60(59)$. Strial punctures on male dise fine, shallow, almost obsolete on declivity; female concavity ending below upper level of eyes; Colima; 0.9-1.3 mm $\qquad$ 65. mendicus (Wood)

- Strial punctures on male disc larger, on declivity fine, distinct, confused; female frontal concavity extending above upper level of eyes; Colima; 0.8-1.1 mm

66. pumilus (Wood)

## 1. Pseudothysanoes recavus Wood

Pseudothysanoes recarus Wood, 1974, Brigham Young Univ. Sci. Bull.. Biol. Ser. 19(1):14 (Holotype, female; 8 km or 5 miles S Simojovel, Chiapas, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from dimorphus (Schedl), from Brazil, by the larger, deeper strial punctures, by the more deeply excavated female frons, with the impression extending only slightly above the eyes, by the presence of a dense fringe of short setae on the upper margin of the female frontal concavity, and by the stouter elytral scales.

Female.- Length 1.2-1.4 mm (males 1.2 mm ), 2.2 times as long as wide; color very dark brown, almost black.

Frons deeply, rather broadly concave from epistoma to slightly above eyes; premandibular epistomal lobe rather well developed; surface of concavity reticulate on upper two-thirds, smooth below; upper margin of concavity bearing a dense fringe of scalelike setae on median two-thirds; epistoma with a few long, subplumose setae in lateral areas. Antemnal scape strongly triangular, two and one-half times as wide as long,
bearing a dense brush of long hair somewhat more elaborate than in dimorphus; club moderately large, elongate-oval, minutely pubescent, entirely devoid of sutures.

Pronotum 0.91 times as long as wide; as in dimorphus except posterior areas more finely reticulate, and granules between summit and basal margin slightly larger.

Elytra 1.4 times as long as wide; outline as in dimorphus; striae not impressed; punctures rather fine, distinctly impressed, interstriae rather smooth, shining, almost twice as wide as striae, punctures very fine, uniseriate. Declivity steep, convex; interstrial punctures replaced by rounded granules of similar size and appearance to those of dimorphus, but more widely spaced. Vestiture of rows of minute, fine, recumbent, strial hair, and rows of erect, interstrial scales; each white scale about five times as long as wide, almost as long as distance between rows, slightly longer than distance between scales within a row.

Male.-Similar to female except body 1.9 times as long as wide; frons rather weakly convex, rugose-reticulate, vestiture sparse, less conspicuous; anterior margin of pronotum armed by eight small teeth; interstrial
punctures on disc finely granulate; interstrial scales less than one and one-half times as long as wide.

Distribution.- Chiapas.
MEXICO: Chiapas: 8 km S Simojovel, 4-VII-69, D. E. Bright.

Notes. - The above treatment was based on the type series of 64 specimens.

## 2. Pseudothysanoes turnbowi Wood

Pseudothysanoes turnboui Wood, 1977, Great Basin Nat. 37:2I7 (Holotype, female; Bentsen-Rio Grande State Park, Hidalgo Co., Texas; Wood Coll.)
Diagnosis.- This species is distinguished from recavus Wood by the smoother, more brightly shining pronotum and elytra, by the less deeply, more extensively excavated female frons, which has punctures and small, stout setae in the excavated area, and by the more slender scales on the male declivity.

Female.- Length 1.2-1.4 mm, 2.3 times as long as wide; color very dark brown, vestiture pale.

Frons similar to recavus except less strongly, more extensively impressed, surface of impressed area smooth, shining, with sparse punctures and stout setae.

Pronotum as in recavus except smoother, interstrial setae slightly longer, more slender.

Elytra as in recavus except smoother, interstrial setae slightly longer, more slender.

Male.-Similar to male recavus except differing by smoother frons, pronotum, and elytra and by the much more slender declivital setae, each seta about three times as long as wide.

Distribution.-Texas.
USA: Texas: Bentsen-Rio Grande State Park, Hidalgo Co., emerged 29-XII-75 to 8-VIII-76, Prosopis glandulosa, R. H. Turnbow.

Notes. - The above treatment was based on the type series of 66 specimens.

## 3. Pseudothysanoes excavatus (Wood)

Cryptulocleptus excavatus Wood, I969, Brigham Young Univ. Sci. Bull., Biol. Ser. IO(2):33 (Holotype, male; 30 km SE El Cameron, Oaxaca, Mexico; Wood Coll.)
Diagnosis.- This remarkable species is unique in the genus. It is distinguished by the remarkably extensive frontal excavation of both sexes; its larger size and the short, tufted scape also aid in distinguishing it.

Male.- Length $1.4-1.6 \mathrm{~mm}, 2.1$ times as long as wide; color dark brown to black.

Frons very broadly, deeply, concavely excavated from eye to eye, from epistoma to vertex, upper margin acute, with its median fourth projecting cephalad slightly; surface reticulate, glabrous. Mandibles near middle armed by a transverse, strongly developed ridge. Antennal scape slightly longer and twice as wide as pedicel; club twice as long as wide, devoid of sutures.

Pronotum 0.89 times as long as wide; widest two-fifths pronotum length from base, sides and anterior margin equally rounded on an almost circular arc; anterior margin armed by two small teeth; summit at middle, broad; anterior slope very coarsely asperate; posterior areas almost smooth, obscurely reticulate, shining; small scales almost obsolete except at margins.

Elytra 1.2 times as long as wide, 1.4 times as long as pronotum; widest at base, sides straight on basal two-thirds, very feebly converging posteriorly, broadly rounded behind; striae not impressed, punctures small, shallow, somewhat obscure; interstriae wider than striae, minutely subrugulose, shining, punctures fine, obscure. Declivity steep, convex; strial punctures greatly reduced, becoming obsolete; interstrial punctures finely gran ulate. Vestiture consisting of minute, fine, strial hair and rows of erect interstrial scales; each scale on disc slender, elongate, slightly longer than distance between rows, becoming shorter but not narrower toward declivity, on declivity each scale equal in length to little more than half distance between rows, about twice as long as wide. Posterior margin of sternum 5 narrowly rounded, projecting slightly.

Female.- Similar to male except 2.3 times as long as wide; frontal excavation slightly deeper, with median area near epistoma slightly elevated; mandibular ridge absent; scape wider, bearing a small tuft of hair; margin of pronotum unarmed; discal scales on elytra slightly shorter; sternum 5 less strongly produced.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 30 km SE El Cameron, 21-VI-67, 1000 m , No. 78, S. L. Wood.

Host.- Gossypium sp.

Biology.- This species was taken from twigs of a small tree with obesus.

Notes. - The above treatment was based on the type series of five specimens.

## 4. Pseudothysanoes querneus Wood

Pseudothysanoes querneus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):20 (Holotype, male; 17 km E Pachuca, Hidalgo, Mexico; Wood Coll.)
Diagnosis.- This species is rather closely related to quercinus Wood, but it may be distinguished by the more coarsely punctured, rugulose pronotal disc, by the coarser strial punctures, and by the much wider elytral scales.

Male.- Length 1.2-1.5 mm, 2.5 times as long as wide; color black.

Frons convex, a slight transverse impression just above epistoma; surface obscurely, rather coarsely punctured, rugulose; vestiture of moderately abundant, rather short, coarse setae. Antennal scape short, broad, slightly longer than pedicel; club rather small, widest through segment 2 , sutures 1 and 2 slightly procurved, 1 marked by setae only at sides.

Pronotum 0.87 times as long as wide; widest on basal third, sides arcuately converging toward broadly rounded anterior margin; anterior margin armed by six low teeth; summit at middle, moderately high; anterior slope asperate; posterior area coarsely, indistinctly punctured, rugulose. Vestiture moderately abundant, stout.

Elytra 1.6 times as long as wide; sides straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures moderately coarse, rather deep; interstriae as wide as striae, somewhat irregular, punctures rather fine, uniseriate. Declivity steep, convex; striae irregularly, weakly impressed, interstrial punctures with coarse, low granules; most of surface obscurely subgranulose. Vestiture of semirecumbent strial hair, and rows of equally long, erect interstrial scales; each scale about twice as long as wide.

Female.- Similar to male except antennal scape as wide as long, bearing a tuft of very long white hair; teeth on anterior margin of pronotum smaller, some obsolete; interstrial scales slightly longer and more slender, each about three to four times as long as wide.

Distribution.- Nuevo León to Veracruz.
Mexico: Nuevo León: Chipinque Mesa, Monterrey, 26-IV-69, D. E. Bright. Hidalgo: 17 km E Pachuca, $10-$ V1-67, 2500 m, No. $5 ; 8 \mathrm{~km}$ W Tulacingo, 11-V1-67, 2400 m , No. 10, both from Quercus by me. Querétaro: 129 km NE San Juan del Río on Highway 120, 9-VI-71, 2700 m , Quercus, D. E. Bright. Veracruz: Huatusco, 7-Vll-67. 300 m, No. 173. Quereus, S. L. Wood.

Host.- Quercus spp.
Biology.- Specimens were taken from phloem tissues of twigs of three different species of oak.

Notes.- The above treatment was based on the type series of 44 specimens and on several other specimens.

## 5. Pseudothysanoes coniferae Wood

Aphanocleptus coniferae Wood, 1960, Great Basin Nat. 20:64 (Holotype, female; 30 km W La Laja, Chihuahua, Mexico; Wood Coll.)
Diagnosis.- This is the most distinctive species of those here placed in the subgenus Aphanocleptus. It is somewhat allied to querneus Wood and quercinus Wood, but it may be distinguished by the shining, coarsely punctured pronotal disc, by the coarse strial punctures, by the more abundant vestiture, by the host, and by other characters.

Male.- Length $1.3-1.7 \mathrm{~mm}, 2.5$ (female 2.7) times as long as wide; color dark brown to almost black.

Frons convex, transversely impressed just above epistoma, a very weak impression in central area; surface obscurely reticulate, finely, rather closely punctured; vestiture of moderately abundant, coarse, moderately long setae. Antennal scape short, as wide as long, not longer than pedicel; club small, 1.7 times as long as wide, widest through segment 2 , with two straight sutures.

Pronotum 0.97 times as long as wide; subcircular, widest just behind middle; anterior margin armed by four teeth; summit at middle, anterior area asperate; posterior area smooth, shining, coarsely, very closely, rather deeply punctured. Vestiture of rather abundant, coarse, long setae.

Elytra 1.7 times as long as wide, 2.0 times as long as pronotum; sides straight and parallel on more than basal two-thirds, rather broadly rounded behind; striae not impressed, punctures coarse, deep; interstriae narrower than striae, smooth, punctures fine, uniseriate. Declivity steep, convex; striae
weakly impressed; interstrial punctures very feebly granulate. Vestiture of stout strial hair, and rows of slightly longer, abundant interstrial scales; each scale from one to three times as long as wide, each shorter than distance between rows but longer than distance between scales within a row.

Female.-Similar to male except usually slightly larger and more slender; frons more distinctly impressed; scape more broadly expanded and ornamented by long hair.

Distribution.- Chihuahua and Nuevo León.

Mexico: Chihuahua: 30 km W La Laja, 16-VII-60, about 2500 m, Picea, S. L. Wood; 26 km NE San Juanito, 19-VII-60, Douglas fir, S. L. Wood. Nuevo León: Cerro Potosí.
Hosts.-Picea chihuahuensis, Pseudotsuga menzeisii.

Biology.- Shaded out branches about 2-6 cm in diameter in living trees were selected for attack. Parental galleries consisted of an irregular nuptial chamber, from which two transverse egg tunnels extended in opposite directions, each about 1 cm in length. Both nuptial chamber and egg galleries engraved both wood and phloem. Larval mines engraved the wood very lightly, parallel to its grain, and extended up to 4 cm from the egg tunnel.

Notes.- The above treatment was based on the type series of 40 specimens and on 3 other specimens.

## 6. Pseudothysanoes obesus (Wood)

Cryptulocleptus obesus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):33 (Holotype, male; 30 km SE El Cameron, Oaxaca; Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from quercinus Wood by characters summarized in the above key.
$M_{\text {ALE }}$ - Length $1.0-1.2 \mathrm{~mm}$ (females $1.2-1.4 \mathrm{~mm}$ ), 2.0 (female 2.3) times as long as wide; color reddish brown, elytra black (lighter in less mature specimens).
Frons planoconvex almost to upper level of eyes; minutely punctate above, becoming smoother below; vestiture consisting of a few short subplumose setae over flattened area. Scape short, little longer than pedicel, bearing a small tuft of hair; club moderately large, oval.

Pronotum 0.86 times as long as wide; widest one-third pronotum length from base, sides rather strongly arcuate, converging toward narrowly rounded anterior margin; anterior margin armed by four teeth, median pair larger; summit behind middle, well developed; anterior area coarsely asperate; posterior area very minutely rugose, punctures obscure. Vestiture largely scalelike.

Elytra 1.15 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, rather broadly rounded behind; striae not impressed, punctures small, obscure; interstriae wider than striae, punctures fine, uniseriate. Declivity steep, broadly convex; surface minutely rugose, as on disc, except interstrial punctures closer. Vestiture consisting of interstrial rows of erect scales, each scale less than twice as long as wide.

Female.- Similar to male except 2.3 times as long as wide, frons shallowly concave to upper level of eyes; scape larger, broadly triangular, bearing a large tuft of long hair; anterior margin of pronotum unarmed; elytra minutely rugose, all punctures obscure.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 30 km SE El Cameron, 21-VI-67, 1000 m, No. 79 , Gossypium. S. L. Wood.

Biology.- Specimens were removed from dying twigs of a small shrubby tree identified as Gossypium sp. The beetles were removed from the cambium region.

Notes.- The above treatment was based on the type series of 28 specimens.

## 7. Pseudothysanoes quercinus (Wood)

Cryptulocleptus quercinus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 30$ (Holotype, male; $37 \mathrm{~km} W$ Durango. Durango, Mexico: Wood Coll.)
Diagnosis.- This species may be distinguished by characters summarized in the above key, although it is not closely related to any known species.

Male.- Length $0.8-1.1 \mathrm{~mm}$ (females 1.2-1.5), 2.4 (female 2.8) times as long as wide; color very dark brown.

Frons convex, narrowly, transversely impressed just above epistoma; surface rugosereticulate, punctures fine; vestiture moderately abundant, conspicuous, subplumose,
moderately short. Scape only slightly longer than pedicle, bearing several long setae.

Pronotum 0.81 times as long as wide; widest near middle, subcircular in outline; anterior margin armed by four small teeth; summit at middle, rather high, anterior slope rather coarsely asperate; posterior area smooth, shining, punctures sparse, very minute; vestiture consisting of stout, erect hair posteriorly, of bifid scales in asperate area.

Elytra 1.6 times as long as wide, 1.9 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures of moderate size and depth; interstriae almost smooth, as wide as striae, punctures fine, uniseriate. Declivity rather steep, convex; essentially as on dise but surface more irregular. Vestiture consisting of fine, short, strial hair and rows of erect, interstrial scales; each scale one and one-half times as long as strial hair, about two-thirds as long as distance between rows, similarly spaced within each row, each scale about twice as long as wide.

Female.- Similar to male except 2.8 times as long as wide; frons as in male; scape very slightly larger, bearing a large, long tuft of hair; anterior margin of pronotum unarmed; strial punctures not as deep, more widely spaced; declivity less clearly punctured; elytral scales more closely spaced within rows, very slightly longer, each scale about four times as long as wide.

Distribution.- Durango to Oaxaca.
MEXICO: Durango: $37 \mathrm{~km} W$ Durango, $4-\mathrm{V} 1-65$, 2000 m , No. 10, Quereus, S. L. Wood. Oaxaca: Putla, 14-V-71, Quercus, D. E. Bright.

Host.-Quercus sp.
Brology.- The Durango series was taken from tunnels in the phloem of an unthrifty branch 2 cm in diameter.

Notes.- The above treatment was based on the type series of 34 specimens and on several other specimens.

## 8. Pseudothysanoes concentralis Wood

Pseudothysanoes concentralis Wood, 1975, Great Basin Nat. 35:27 (Holotype, female; 10 km or 6 miles SE Totolapan, Oaxaca, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from quercinus Wood by the concentric, carinate pronotal asperities, by the more
strongly impressed frons, by the greatly reduced elytral punctures, and by the wider elytral scales.

Female.- Length $1.0-1.2 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown.

Frons rather strongly concave on median two-thirds of area below upper level of eyes, surface subrugose, with sparse granules except almost smooth on lower half of concavity; vestiture short, sparse. Antennal scape as wide as long, as long as pedicel, bearing a small tuft of long hair; club about as in quercinus.

Pronotum 0.73 times as long as wide; outline as in quercinus; summit at middle; anterior slope on median third armed by six concentric, uniform, transverse carinae, other asperities absent, carina 1 submarginal, sixth at summit; posterior areas shining, almost smooth, punctures almost obsolete. Vestiture consisting of a row of scales posterior to each of first five carinae, and rather sparse, coarse hair in remaining areas.

Elytra 1.8 times as long as wide, 1.4 times as long as pronotum; outline as in quercinus; striae not impressed, punctures small, shallow; interstriae almost smooth, about twice as wide as striae, punctures almost obsolete; surface usually covered by a thin incrustation. Declivity convex, steep, sculpture as on dise but punctures even more obscure. Vestiture mostly abraded, consisting of widely spaced, short, interstrial scales, each scale one and one-half to two times as long as wide.

Male.- Length 0.8 mm ; similar to female except smaller, slightly stouter; frontal concavity not as deep; pronotal asperities not fused or clearly concentric.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 10 km SE Totolapan, 21-VI-67, 1000 m , No. 73 , leguminous roadside shrub with a yellow flower, possibly Cassia, S. L. Wood.

Notes.- The above treatment was based on the type series of 26 specimens.

## 9. Pseudothysanoes thomasi Wood

Pseudothysanoes thomasi Wood, 1967, Great Basin Nat. 27:38 (Holotype, male; Mazatlán, Sinaloa, Mexico; Canadian Nat. Coll.)
Diagnosis.- This unique species is placed near brunneus Wood and sedulis Blackman, although it is not closely related. The small
size and the unusual elevation on the male declivital interstriae 3 serve to distinguish it.

Male.- Length $1.0-1.2 \mathrm{~mm}, 2.5$ times as long as wide; color light brown.

Frons broad, weakly convex below upper level of eyes, with epistomal area distinctly elevated, more strongly convex above eyes; surface finely rugose and with a small, rounded granule at base of each seta; vestiture consisting of moderately long, abundant, fimbriate setae, those above directed dorsad, those on epistoma directed orad. Antennal scape short, subcircular, scarcely longer than pedicle; club 1.4 times as long as wide; pubescent, sutures indistinctly indicated.

Pronotum 0.94 times as long as wide; sides strongly arcuate, widest just behind middle; summit distinct, asperities moderately large; anterior margin armed by eight coarse, basally separate teeth; surface behind summit minutely reticulate, with a few small, rounded, squamiferous granules; vestiture consisting of semierect scales and a few inconspicuous bristles.

Elytra about 1.5 times as long as wide; sides straight and subparallel on basal twothirds, rather broadly rounded behind; striae feebly impressed, punctures minute, distinguished with difficulty from those of interstriae; interstriae subrugose, punctures indistinct. Declivity convex, moderately steep; interstriae 2 strongly narrowed below, 3 with large unarmed elevation extending about two-thirds length of declivity from base, ending abruptly below, its base as wide as 1 and 2 combined, its height slightly less than its basal width. Vestiture consisting of rows of short, recumbent, hairlike, strial setae, and slightly longer scalelike setae; each scale on posterior half at least as wide as long.

Female.-Similar to male except frons more strongly impressed; strial punctures more strongly impressed; elytral declivity devoid of elevation; interstriae 2 almost normal; elytral scales slightly more slender.

Distribution.-Sinaloa.
MEXICO: Sinaloa: Mazatlán, VIII-64, J. B. Thomas.
Biology.- Except that it was taken from the bark of a tree, nothing is known of the habits of this species.

Notes. - The above treatment was based on two male and two female paratypes in my collection.

## 10. Pseudothysanoes brunneus Wood

Pseudothysanoes brunneus Wood, 1971, Great Basin Nat. 31:72 (Holotype, male; Miller Canyon, Huachuca Mts., Arizona; Wood Coll.)
Diagnosis.- This species is distinguished from sedulus Blackman by the smaller size, by the more widely spaced strial punctures, by the more slender elytral scales, and by the lighter body color.

Male.- Length 0.9-1.3 mm, 2.4 (female 2.7) times as long as wide; color brown.

Frons convex, a transverse impression just above epistoma; surface rather coarsely, closely, subrugulosely punctured; vestiture of moderately abundant, coarse, short setae. Scape very slightly longer than wide, as long as pedicel; club small oval, suture 1 indicated by setae only at sides, 2 weakly procurved.

Pronotum 0.86 times as long as wide; subcircular, anterior margin armed by about four to six small teeth; summit high, anterior slope asperate; posterior area shining, with fine, close punctures and granules. Vestiture of stout, rather short, moderately abundant setae.

Elytra 1.6 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures rather coarse, deep; interstriae narrower than striae, almost smooth, fine, uniseriate punctures on anterior half of disc replaced by fine granules on posterior half. Declivity convex, steep; interstriae 1 slightly, 3 and 9 distinctly elevated, all interstriae with a row of fine granules. Vestiture of rows of fine, short, strial hair, and rows of erect interstrial scales; each scale two to three times as long as wide, shorter than distance between rows of scales or between scales within a row.

Female.- Similar to male except body more slender, 2.7 times as long as wide, scape slightly wider and ornamented by a small tuft of hair; strial punctures much smaller, interstriae wider than striae and devoid of granules on disc; elytral scales about four to five times as long as wide.

Distribution.-Arizona to Chihuahua.
USA: Arizona: Madera Canyon, Santa Rita Mits., 10-VII-52, Qucrcus; Miller Canyon, Huachuca Mts., $10-\mathrm{VII}-$ 52. Quercus. MEXICO: Chihuahua: 40 km S Creel, 18 -VII-60, Quercus, S. L. Wood.

Hosts. - Quercus spp.

Biology.- Small, broken oak twigs were selected for attack. Specimens were removed from phloem tissues.

Notes.- The above treatment was based on the type series of 19 specimens and on 13 other specimens.

## 11. Pseudothysanoes sedulus Blackman

Pseudothysanoes scdulus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Bull. 25:204 (Holotype, male; Bear Canyon, Catalina Mts., Arizona; U.S. Nat. Mus., 27138)

Pseudothysanoes gambetti Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Bull. 25:205 (Holotype, male; Pelonillo Reserve, New Mexico; U.S. Nat. Mus.); Wood, 197I, Great Basin Nat. 31:151. Synonymy
Pseudothysanoes barberi Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Bull. 25:206 (Holotype, male; Williams, Arizona; U.S. Nat. Mus., 27137); Wood, 1971, Great Basin Nat. 31:151. Synonymy
Diagnosis.- This species is allied to brunneus Wood, but it may be distinguished as noted in the diagnosis of brumneus and in the key.

Male.- Length $1.4-1.7 \mathrm{~mm}, 2.3-2.4$ (female 2.5) times as long as wide; color black.

Frons and pronotum as in brunneus except anterior margin of pronotum armed by six to eight teeth, disc closely, rather coarsely, subrugosely punctured.

Elytra 1.4-1.5 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures moderately coarse, deep; interstriae as wide as striae, almost smooth, punctures uniseriate, finely granulate. Declivity convex, steep; striae with punctures smaller, rather obscure; interstriae 3 weakly to moderately elevated, all interstriae uniseriately, rather coarsely granulate, 3 often with a partial double row; declivital surface obscurely rugose. Vestiture consisting of fine, short, strial hair, and interstrial rows of erect scales, each scale one to two times as long as wide, two-thirds as long as distance between rows, slightly longer than distance between scales within a row.

Female.- Similar to male except body more slender, 2.5 times as long as wide, scape much wider; bearing a tuft of long hair; strial punctures slightly smaller, interstrial punctures finer, not at all granulate on dise or
declivity; elytral scales about two to almost three times as long as wide.

Distribution.-Arizona to New Mexico.
USA: Arizona: Bear Canyon, Santa Catalina Mts., 4 -II-08, Hopk. US 7175-2, Quercus, 30-1II-08, Hopk. US 7189, Q. emoryi, Q. gambelii, 20-VIII-14, Hopk. US 12687, Oak, M. Chrisman; Prescott N.F., 17-V-30, Hopk. US 20403-k. Quercus, M. W. Blackman; Tucson, 9-I-08, Q. emoryi, M. Chrisman; 6 km S Prescott, 5-VI-69, 1700 m, No. 29, Quercus, W. G. Harwood; Williams, 26-IX01. Qucreus, 1I-02, 9426-29, Oak, Schwarz and Barber. New Mexico: Mayhill, 4-VI-69, No. 47, Quercus, S. L. Wood; Peloncillo Reserve, bred 12-XI-07, 6-I-08, Hopk. US 5589, Quercus, J. L. Webb.

Hosts.- Quercus emoryi, Q. gambelii, and Q. spp.

Biology.- Dying or unthrifty, standing host material about $2-6 \mathrm{~cm}$ in diameter was selected for attack. Specimens were removed from phloem tissues.

Notes.- The above treatment was based on the holotypes of sedulus, gambetti, and barberi, and on 167 other specimens.

## 12. Pseudothysanoes vallatus Wood

Pseudothysanoes vallatus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 24$ (Holotype, male: Voleán Colima, Jalisco, Mexico; Wood Coll.)
Diagnosis.- This remarkable species is entirely unique in the genus. Presumably it is allied to lecontci Blackman, but the male declivital interstriae 3 are exceedingly strongly elevated and very coarsely serrate, the height of the elevation exceeds the combined widths of interstriae 1 and 2,1 is neither elevated nor serrate, and in the female the elevation on 3 is only moderately developed.

Male.- Length $1.0-1.3 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown.

Frons convex, a slight transverse impression just above epistoma; surface rather coarsely reticulate except almost smooth on epistomal area; vestiture rather sparse, moderately long, consisting of subplumose setae. Scape short, only slightly longer but distinctly wider than pedicel, club small, oval, two weakly arcuate sutures indicated by setae.

Pronotum subcircular in outline, anterior margin armed by two subcontiguous teeth; anterior slope asperate, summit at middle; posterior area transversely substrigosereticulate with a few very small granules, more regularly reticulate laterally; vestiture
consisting of rather sparse, slender scales and hair of equal length intermixed.

Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel on basal two-thirds, then rounded to meet broadly truncate apex; striae not impressed, punctures small, distinct; interstriae slightly narrower than striae, each bearing a uniseriate row of small, rounded, squamiferous granules. Declivity rather steep; flattened to weakly excavated between very strongly, very narrowly elevated interstriae 3 , 1 feebly elevated toward apex, punctures of striae 1 and 2 more strongly impressed than on disc; interstriae 3 elevated to sutural apex, armed by 10 very coarse, contiguous, blunt teeth that increase in size to just below middle of declivity; interstriae 1-9 each bearing one to three rounded nodules at base of declivity, those on 7 largest. Vestiture consisting of rows of interstrial scales and smaller strial hair; scales longer on declivity, particularly those on summit of elevated crest of interstriae 3.

Female.-Similar to male except frons weakly impressed to upper level of eyes and more finely sculptured; scape slightly larger and bearing a small tuft of hair; anterior margin of pronotum unarmed; declivital interstriae 3 only moderately elevated and unarmed, nodules at base of declivity also absent.

Distribution.-Jalisco.
MEXICO: Jalisco: Volcán Colima, 23-V1-65, 2500 m , No. 105, S. L. Wood.

Host.- Struthanthus venetus.
Biology.-This species was taken from dying branches of mistletoe in series with large numbers of Micracisella monadis Wood and of another Pseudothysanoes; consequently, it was overlooked at the time of collection and nothing was recorded of its habits.

Notes.- The above treatment was based on the type series of 14 specimens.

## 13. Pseudothysanoes securus Wood

Pseudothysanoes securus Wood, 1977, Great Basin Nat. 37:216 (Holotype, female; 8 km or 5 miles W Tulacingo, Hidalgo, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from quercicolens Wood by the much longer, more slender, flattened process on the female
scape, by the more slender, more acutely pointed antennal club, by the more slender, more isolated pronotal asperities, and by many other characters.

Female. - Length $1.5 \mathrm{~mm}, 2.9$ times as long as wide, color black, vestiture white.

Frons about as in quercicolens except surface rugose-reticulate. Scape acutely triangular, twice as wide as long, ornamented by a conspicuous tuft of rather long hair; club small, twice as long as wide, acutely pointed at apex, sutures obscure.

Pronotum about as in quercicolens except anterior margin unarmed, asperate area smaller, asperities smaller, more slender.

Elytra about as in quercicolens except strial punctures not as deep, interstriae more irregular, punctate granules larger, closer; declivital striae 1 and 2 with punctures reduced, interstriae 2 narrower, flat, 3 with weak elevation not reaching junction with 9 . Vestiture white, closer, interstrial scales on disc one and one-half to two times as long as wide, on declivity about as long as wide.

Distribution.- Hidalgo.
MEXICO: Hidalgo: 8 km W Tulancingo, 11-VI-67, 2400 m, No. 12, Quercus, S. L. Wood.

Notes. - The above treatment was based on the type series of two specimens.

## 14. Pseudothysanoes quercicolens Wood

Pseudothysanoes quercicolens Wood, 1956, Canadian Ent. 88:235 (Holotype, male; 50 km SW El Salto, Durango, Mexico; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species is distinguished from lecontei Blackman and sedulus Blackman by characters summarized in the above key.

Male.- Length $1.3-1.6 \mathrm{~mm}, 2.5$ times as long as wide; color darker brown to almost black.

Frons as in brunneus Wood. Scape short, longer than wide, as long as pedicel; club moderately large with two weakly procurved sutures. Pronotum as in sedulus.

Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures rather coarse, deep; interstriae slightly narrower than striae, subrugose, punctures very fine, uniseriate, becoming granulate toward declivity. Declivity convex, steep; strial
punctures smaller, less distinctly impressed; interstriae 3 and 9 elevated, almost as high as wide; all interstriae uniseriately granulate. Vestiture consisting of fine, semirecumbent, strial hair and rows of slightly longer, erect interstrial scales; each scale as long as distance between rows, separated within a row by a slightly shorter distance, each about four to six times as long as wide.

Female.- Similar to male except frons more finely punctured; scape as wide as long, bearing a tuft of long hair; declivital interstriae 3 and 9 less strongly elevated, all interstrial granules finer.

Distribution.-Sinaloa and Durango to Michoacán.
MEXICO: Durango: 50 km SW El Salto, 23-VII-53. 2700 m , Quercus, S. L. Wood. Michoacán: 10 km E Volcán Paricutin, 19-V1-65, 2500 m , No. 86, Quercus, S. L. Wood. Sinaloa: 30 km NE Copala, 27-VII-53, 1000 m , Quercus, S. L. Wood.

Hosts.- Quercus spp.
Biology.- Specimens were taken from phloem tissues of recently cut or broken oak branches about 2-6 cm in diameter.

Notes.- The above treatment was based on 24 paratypes and on 31 other specimens.

## 15. Pseudothysanoes lecontei Blackman

Pseudothysanoes lecontei Blackman, 1920, Mississippi Agric. Expt. Sta. Tech. Bull. 9:4 (Holotype, male; Washington, D.C.; Mus. Comp. Zool., 14357)
Diagnosis.- This species is distinguished from sedulus Blackman by characters summarized in the above key.
Male.- Length $1.1-1.4 \mathrm{~mm}, 2.5$ (female 2.7) times as long as wide; color dark brown.

As in sedulus except punctures on pronotal disc very slightly larger; declivital interstriae 2 more narrowly elevated, 2 and 4-8 each with a row of granules, 2 also bearing a row of scales; elytral scales each three to almost four times as long as wide.

Female.- Similar to male except differing in same way female of sedulus differs from male.

Distribution.-New York to North Carolina.

USA: District of Columbia, Maryland, New Jersey, New York, North Carolina, Pennsylvania, Virginia, West Virginia.

Hosts.- Castenea dentata, Celtis sp., and Quercus spp.

Biology. - Reared from the bark of twigs and branches of the host trees.

Notes.- The above treatment was based on the holotype and on 133 other specimens.

## 16. Pseudothysanoes furvescens Wood

Pseudothysanoes furcescens Wood. 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):21 (Holotype, male; 18 km N Huajuapan, Oaxaca, Mexico: Wood Coll.)
Diagnosis.- This species is in the phoradendri group and is very closely related to furvus Wood. From furvus it is distinguished by the absence of granules on the male discal interstriae, and by the shorter elytral scales.

Male.- Length 1.1-1.4 mm, 2.3 (female 2.8) times as long as wide; color black.

Frons convex, transversely impressed above epistoma; surface finely rugose, punctures not evident; vestiture of sparse, coarse, short setae. Antennal scape elongate; club moderately large, oval, widest at middle, suture 1 straight, 2 obscure.

Pronotum as in furvus.
Elytral proportions and outline as in furvus; striae not impressed, punctures small, shallow; interstriae slightly wider than striae, smooth, punctures very fine, not at all granulate or elevated. Declivity convex, steep; striae as on disc; interstriae each with a row of fine granules. Vestiture consisting only of rows of interstrial scales, each scale about three times as long as wide, slightly shorter than distance between rows, spaced within a row by about one and one-half times length of a scale.

Female. - Similar to male except more slender, 2.8 times as long as wide, frons less strongly convex; anterior margin of pronotum unarmed; strial punctures much smaller, obscure; occasional strial hair present.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 18 km N Huajuapan, 15-VI-67, No. 42, Phoradendron, S. L. Wood.

Biology.- Unthrifty or injured mistletoe was selected for attack by this species. The gallery systems were in the phloem tissues.

Notes. - The above treatment was based on the type series of 16 specimens.
17. Pseudothysanoes furvus Wood Pseudothysanoes furvus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):26 (Holotype, male; Cañas, Guanacaste, Costa Rica; Wood Coll.)

Diagnosis.- This species is distinguished from furvatus Wood by the presence of granules on the discal interstriae of the male. These two species may be recognized from other species in the phoradendri group by the short scales on the male elytral declivity.

Male.- Length $1.1-1.4 \mathrm{~mm}, 2.2$ (female 2.8) times as long as wide; color black with white scales.

Frons convex above, transversely impressed from just above level of antennal insertion to epistomal margin; surface finely granulate; vestiture consisting of moderately abundant, coarse, short, subplumose hair.

Pronotum 0.93 times as long as wide; widest about one-third pronotum length from base, sides rather strongly arcuate on basal half, laterally constricted on anterior half, narrowly rounded in front; anterior margin armed by eight serrations that decrease in size laterally; summit just behind middle, rather high; coarsely asperate from summit forward; posterior area minutely punctuatesubgranulate and with obscure, fine punctures, more nearly reticulate laterally; vestiture of minute hair and longer, broad scales, those on asperate area longer.

Elytra 1.3 times as long as wide; 1.5 times as long as pronotum; sides straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures small, deep; interstriae almost twice as wide as striae, minutely irregular, subvulcanate squamiferous punctures weakly elevated, almost as large as those of striae. Declivity convex, steep; sculpture about as on disc, but punctures and granules somewhat smaller. Vestiture consisting of interstrial rows of erect scales; each scale as long as distance between rows and between adjacent scales in a row, about three times as long as wide.

Female.- Similar to male except slightly larger, more slender, 2.8 times as long as wide; frons less coarsely sculptured, vestiture more abundant, finer; antennal scape bearing a small tuft of subplumose hair; sculpture of pronotum finer, anterior margin unarmed;
elytral punctures and granules greatly reduced except only slightly smaller on declivity; elytral scales smaller.

Distribution.- Honduras to Costa Rica.
honduras: Zamorano, Morazán, I8-IV-64, 700 m , No. 569, P'oradendron robustissimum. COSTA RICA: Finca La Pacifica, Cañas, Guanacaste, I3-IV-66, 50 m , No. 1, Phoradendron; 20 km SE Liberia, Guanacaste, 10-VII-66, 50 m , No. 16, Phoradendron; all by me.

## Hosts.- Phoradendron spp.

Biology.- This species breeds in the phloem tissues of dead and dying twigs of mistletoe.

Notes.- The above treatment was based on the type series of 72 specimens and on 30 other specimens.

## 18. Pseudothysanoes furvatus Wood

Pseudothysanoes furvatus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 26$ (Holotype, male; 35 km N Juchitlán, Jalisco, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from furvus Wood by the much coarser and deeper male strial punctures, this difference only slight in the female; by the larger, closer, interstrial granules on the male disc; and by the slightly longer, more slender male declivital scales, the female declivital scales being more slender but slightly shorter.

Male.-Length $1.0-1.4 \mathrm{~mm}, 2.3$ (female 2.8) times as long as wide; color dark brown to black, with summit of pronotum reddish.

Frons and pronotum as in furvus.
Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures moderately large, deep; interstriae slightly narrower than striae, smooth, each with a uniseriate row of rather small, rounded, squamiferous granules, each granule as wide as its interstriae. Declivity beginning at or just behind middle, rather steep, convex; sculpture as on disc except granules smaller, many obscure. Vestiture consisting of rows of erect interstrial scales, each scale on disc two to three times as long as wide, each equal in length at base to two-thirds distance between rows at base of declivity; each scale on declivity about four to six times as long as wide and slightly longer than distance between rows.

Female.- As in female of furvus except as noted in the diagnosis above.

Distribution.- Jalisco.
Mexico: Jalisco: 35 km N Juchitlán, 3-vil-65, 1.300 m, No. 18:3, Phoradendron, S. L. Wood.

Biology.- As in furvus, except the host tree of the mistletoe was not identified.

Notes.- The above treatment was based on the type series of 33 specimens.

## 19a. Pseudothysanoes leechi Wood

Pseudothysanoes leechi Wood, 1980. Great Basin Nat. 40:356 (Holotype, male; 3 km NNE Angwin, Napa Co., Califormia; Calif. Acad. Sci.)
Diagnosis.- This species is distinguished from phoradendri Blackman by the larger size, by the much shorter, stouter male declivital scales, and by the much longer setae on the female vertex. From the more closely related verdicus Wood it is distinguished by the stouter scales on the male declivity, by the much less strongly impressed female frons, with the setae on the vertex distinctly shorter and less abundant, and by other characters cited below.

Male.- Length 1.4-1.7 mm, females $1.6-1.8 \mathrm{~mm}, 2.4$ (females 2.5 ) times as long as wide; color very dark brown, vestiture pale.

Frons as in verdicus except median third on lower half of frons more distinctly, concavely impressed.

Elytra 1.45 times as long as wide, 1.7 times as long as pronotum; as in verdicus except strial punctures on dise slightly larger, interstrial granules distinctly larger, extending to base, interstrial scales closer, shorter, those on declivity about twice as long as wide, each half to two-thirds as long as distance between rows.

Female.- Similar to female verdicus except frons shallowly concave on median twothirds of lower two-thirds, setae on vertex shorter, less abundant, tips of longest attaining middle of frons; posterior areas of pronotum without reticulation; strial punctures slightly deeper, interstrial punctures and scales closer, scales distinctly shorter. A very small tuft of hair on scape.

Distribution.- California.
USA: California: North side Howell Mt., 3 km NNE Angwin, Napa Co., 18-V1 to 27-Vill-80, Phoradendron flatescens var. cillosum (on Quercus kelloggii), H. B. Leech.

Notes.- The above treatment was based on the type series of 33 specimens.

19b. Pseudothysanoes phoradendri Blackman

Pseudothysanoes phoradendri Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Bull. 25:202 (Holotype, male; Victoria, Texas; U.S. Nat. Mus., 27139)

Diagnosis.- This is one of about a dozen species in this genus entirely restricted to mistletoes of the genus Phoradendron, nine of which form a rather compact group. This species is most closely allied to furvatus Wood, from which it may be distinguished by characters summarized in the above key.

Male.- Length $1.0-1.5 \mathrm{~mm}, 2.2$ (female 2.7) times as long as wide; color black, summit of pronotum usually reddish brown.

Frons convex above, transversely impressed just above epistoma and with a small concavity on median third of lower half; granulate-punctate above, becoming smooth and shining in concave area; vestiture sparse, consisting of coarse, erect, moderately long setae. Antennal scape long, slender; club moderately large, oval, two weakly procurved sutures.

Pronotum 0.90 times as long as wide; subtriangular, widest at base, slightly arcuate, converging toward narrowly rounded anterior margin; anterior margin armed by six teeth; summit high, behind middle; anterior slope asperate, posterior area reticulate, subrugulose, punctures fine, obscure, a few fine granules directly behind summit. Vestiture sparse, of a few scales and stout bristles.

Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; sides almost straight on basal two-thirds, slightly wider at declivital base, obtusely angulate behind; striae not impressed, punctures rather coarse, deep, close; interstriae slightly narrower than striae, almost smooth, uniseriately, finely granulate. Declivity broadly convex, beginning at middle of elytra; strial punctures slightly smaller than on disc. Vestiture consisting of rows of interstrial scales; each scale at base about three times as long as wide, increasing in length toward declivity, on declivity each scale about six to eight times as long as wide, at least twice as long as distance between scales within a row or between rows.

Female.-Similar to male except more slender, 2.7 times as long as wide; frontal impression a bit more extensive; antennal scape bearing a small tuft of hair; anterior margin of pronotum unarmed; strial punctures smaller, not as deep; declivity confined to posterior third of elytra; strial hair present on declivity, interstrial scales about four times as long as wide.

Distribution.-S California and Arizona to Chihuahua and W Texas.

USA: Arizona: Catalina Springs, Hubbard and Schwarz; Santa Catalina Mts., Hopk. US 7554, mistletoe. California: Mt. Laguna, San Diego Co., 7-XII-40, Hopk. US 32545, Phoradendron on Quercus kelloggii, D. DeLeon; Ventura Co., 9-IV-06, Hopk. US 2762. Texas: Menard, 13-V-46, mistletoe, L. S. Bottomer; Victoria, 6-III-09, corn stalk (?), and 16-III-11, Phoradendron flavescens, J. D. Mitchell. MEXICO: Chihuahua: 39 km S Creel, 13-VII-60, Phoradendron, S. L. Wood.

Host.-Phoradendron flavescens.
Biology.- This species breeds in the phloem tissues of dying branches of mistletoe.

Notes. - The above treatment was based on the holotype and on 28 other specimens.

## 20. Pseudothysanoes funereus Wood

Pseudothysanoes funereus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):21 (Holotype, male: Volcán Colima, Jalisco, Mexico: Wood Coll.)
Diagnosis.- This species is very closely related to phoradendri Blackman, but it may be distinguished by the more slender body form, by the more rugose pronotal disc, by the much smaller strial punctures on both disc and declivity, and by the near absence of interstrial granules.

Male.- Length $1.3-1.5 \mathrm{~mm}, 2.4$ times as long as wide; body color black.

Head and prothorax as in phoradendri except pronotal dise slightly more rugose.

Elytra 1.5 times as long as wide; sides straight and parallel on basal two-thirds, narrowly rounded behind; striae not impressed, punctures small, shallow, separated by two or more diameters of a puncture; interstriae smooth, at least twice as wide as striae, punctures uniseriate, very small, feebly if at all granulate. Declivity beginning well behind middle, convex; interstrial granules small, regular. Vestiture as in phoradendri.

Distribution.- Jalisco.

MEXICO: Jalisco: Volcán Colima, 23-VI-65, 2500 m , No. 108, Phoradendron longifolium, S. L. Wood.

Biology.- Specimens were just entering the bark of a dying mistletoe that grew in an oak tree.

Notes.- The above treatment was based on the type series of seven specimens.

## 21. Pseudothysanoes funebris Wood

Pseudothysanoes funebris Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):27 (Holotype, male; $27 \mathrm{~km} W$ Durango, Durango, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from bullatus Wood by characters of the male elytral declivity as indicated in the above key.

Male.- Length $1.4-1.8 \mathrm{~mm}, 2.4$ times as long as wide; color black, summit of pronotum reddish.

Frons transversely impressed below upper level of eyes, central area shallowly concave; finely granulate-punctate above eyes, finely punctured below; vestiture consisting of moderately abundant, subplumose setae of moderate length.

Pronotum 0.95 times as long as wide; outline and sculpture as in verdicus except granules in posterior area reduced and setae finer.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; outline as in verdicus; striae not impressed, punctures moderately large, shallow, distinct; interstriae wider than striae, surface somewhat irregularly marked by lines, punctures fine, uniseriate, becoming granulate near declivity. Declivity confined to posterior third, rather steep, convex; strial punctures greatly reduced above, obsolete below; interstriae 1 devoid of granules on lower three-fourths and 2 on lower half, upper half of 2 , all of 3 and 4 and lateral areas armed by moderately large, somewhat pointed, isolated, squamiferous granules. Vestiture consisting of erect scales; each scale on disc about four times as long as wide, almost equal in length to distance between rows, more slender, one and one-half times as long and more widely spaced than on disc; spacing of scales within row on declivity slightly greater than spacing between rows.

Female.- Similar to male except frontal concavity slightly deeper and wider; anterior margin of pronotum unarmed; elytra 1.7
times as long as wide, surface of dise somewhat more irregular; elytral declivity sculptured to apex as on disc; interstrial scales about six times as long as wide, not longer or more widely spaced on declivity.

Distribution.- Durango to Coahuila.
MEXICO: Coahuila: 28 km SE Saltillo, 21-V1- 11,2000 m , mistletoe on juniper, D. E. Bright. Durange: 27 km W Durango, 4-V1-65, 2000 m , No. 9, Phoradendron boleanum, S. L. W'ood; 70 km W Durango, 18-VI-71, 2600 m , mistletoe on oak, D. E. Bright.

## Host.- Phoradendron boleanum.

Biology.- This species was taken from phloem tissues in the dying twigs of the above mistletoe that grew in Arbutus trees. An error occurred in the original description in host designation.

Notes.- The above treatment was based on the type series of 130 specimens. A series from 5 km N Suchixtepec, Oaxaca, on Highway $175,4-$ VI- $71,3100 \mathrm{~m}$, in mistletoe on alder, by D. E. Bright in the Canadian National Collection is assigned to this species, although it represents a slight deviation.

## 22. Pseudothysanoes bullatus Wood

Pseudothysanoes bullatus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):28 (Holotype, male; 42 km SE Nichixtlan, Oaxaca, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from funebris Wood by the large, shining bulla on the male elytral declivity and by other characters mentioned in the above key.

Male.- Length $1.5-2.0 \mathrm{~mm}, 2.3$ times as long as wide; color very dark brown, posterior half of elytra usually lighter.

Frons moderately, transversely impressed on lower half, convex above; surface rather coarsely granulate-punctate above, finely rugose on lower third; vestiture consisting of stout, rather sparse, short, subplumose setae. Scape with about a dozen long setae.

Pronotum 0.94 times as long as wide; widest at base, sides arcuately converging from base to narrowly rounded anterior margin, with a slight constriction one-third pronotum length from anterior margin; anterior margin armed by six small teeth; summit behind middle, well developed, broad; posterior area very finely rugose-reticulate, minute punctures obscure; vestiture of scales and hair intermixed.

Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; outline as in verdicus Wood; striae not impressed, punctures rather small, distinctly impressed; interstriae wider than striae, minutely, irregularly marked by obscure lines and points, squamiferous punctures rather fine, usually distinct, not granulate. Declivity occupying slightly more than posterior third, convex, rather steep; strial and interstrial punctures reduced, becoming obsolete by middle of declivity; points largely replace obscure lines on interstriae, surface shining; interstriae 3 with a large, low bulla on upper part of lower half of declivity, extending slightly to interstriae 2 and 4 . Vestiture consisting of erect, interstrial scales, each about two to three times as long as wide, slightly longer toward declivity, those on upper declivity spaced within and between rows by a distance equal to length of a scale; lower two-thirds of declivity glabrous.

Female.-Similar to male except frons shallowly concave on median three-fourths from epistoma to above upper level of eyes, upper area bearing rather numerous, moderately short, yellow setae; anterior margin of pronotum unarmed and more broadly rounded; declivital interstriae each bearing a uniseriate row of fine granules to apex, bulla obscure; declivity shorter, steeper; vestiture more abundant, extending to apex, each scale more slender, above five times as long as wide.
Distribution- Oaxaca.
MEXICO: Oaxaca: 42 km SE Nochixtlán, 17-VI-67, 2300 m , No. 55 , Phoradendron, S. L. Wood.

Biology.- This species was taken from phloem tissues of a dying mistletoe.

Notes.- The above treatment was based on the type series of 11 specimens.

## 23. Pseudothysanoes ciscivorus Wood

Pseudothysanoes viscivorus Wood. 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):25 (Holotype, male; Volcán Ceboruco, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is in the phoradendri group; it is distinguished from amassius Wood by characters summarized in the above key.

Male.- Length $1.4-1.7 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to black, summit of pronotum reddish.

Frons convex, transversely impressed on lower half, subconcave toward center; surface finely reticulate-granulate, with small, obscure punctures; vestiture of sparse, subplumose setae of moderate length.

Pronotum 0.91 times as long as wide; widest on basal third, sides strongly arcuate on basal half, strongly constricted one-third length from narrowly rounded anterior margin; anterior margin armed by six small teeth; summit behind middle, well developed; anterior slope coarsely asperate to summit; posterior area coarsely reticulate, fine punctures obscure; vestiture of intermixed fine hair and slightly longer, erect scales, each scale about four to six times as long as wide.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae very weakly impressed toward declivity, punctures rather coarse, deep; interstriae almost as wide as striae, punctures uniseriate, rather coarse, subgranulate on anterior margins especially toward declivity. Declivity beginning slightly in front of middle, moderately steep, broadly convex; striae weakly impressed, punctures slightly larger than on disc; interstrial punctures usually not at all granulate. Vestiture consisting of minute strial hair and rows of interstrial scales; each scale on disc slightly shorter than distance between rows, each about three to four times as long as wide; scales on declivity equal in width to those on disc, but three times as long; scales on declivital interstriae 8 and 9 in partial double rows and equal in length to one another.

Female.- Similar to male except anterior margin of pronotum unarmed; elytra 1.5 times as long as wide, declivity restricted to posterior third, more narrowly rounded, steeper; strial punctures smaller, similar on disc and declivity; interstrial granules larger and more regular; declivital vestiture only slightly longer than on disc, each declivital scale about four to six times as long as wide.

Distribution.- Nayarit.
MEXICO: Nayarit: Volcán Ceboruco, 5-VII-65, 1100 m, No. 191, Phoradendron probably robinsomii, S. L. Wood.

Biology.- Specimens were taken from phloem tissues of the above mistletoe.

Notes.- The above treatment was based on the type series of 19 specimens.

## 24. Pseudothysanoes amassius Wood

Pseudothysanoes amassius Wood. 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):25 (Holotype, male; 20 km S Matías Romero, Oaxaca, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished, with some difficulty, from viscivorus Wood, and it eventually may become a subspecies. It is distinguished by a slightly more strongly impressed frons, by the shorter, uniseriate scales on the male declivital interstriae 9 and a reduced number of scales on 8 , and by the much broader interstrial scales of the female.

Male.- Length $1.3-1.6 \mathrm{~mm}, 2.1$ times as long as wide; color dark brown to black, summit of pronotum reddish.

As in viscivorus except frons more broadly, more deeply impressed; strial punctures near declivity somewhat finer, interstrial granules finer; scale son declivital interstriae 9 uniseriate and distinctly shorter than those on 8.

Female.- As in the female of viscivorus except frons broadly, more strongly impressed; interstrial granules much smaller; interstrial scales much broader, each about two to two and one-half times as long as wide.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 20 km S Matias Romero, 24-V1-67, 700 m , No. 93, Phoradendron. S. L. Wood.

Biology.- As in viscivorus.
Notes. - The above treatment was based on the type series of 12 specimens.

## 25. Pseudothysanoes peniculus Wood

Pseudothysanoes peniculus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser, 10(2):28 (Holotype, male; 13 km W Texmelucan, Puebla, Mexico; Wood Coll.)
Diagnosis.- The male of this species resembles funebris Wood, but the female has the frons excavated and elaborately decorated by setae.

Male.- Length $1.4-1.7 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown, part of elytra and summit of pronotum lighter in some specimens.

Frons rather strongly, broadly, transversely impressed on lower half, convex above, epistoma gradually raised to margin; surface finely granulate-punctate, finer in impression; vestiture consisting of moderately abundant, short, subplumose setae.

Pronotum 0.96 times as long as wide; outline as in verdicus Wood; surface behind summit rather coarsely reticulate, minute, sparse punctures obscure; vestiture of scales and stout hair intermixed.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; outline as in verdicus; striae not impressed, punctures small, shallow, obscure; interstriae about as wide as striae, irregularly marked, punctures fine, obscure, very feebly granulate, squamiferous. Declivity on slightly more than posterior third, convex, moderately steep; sculpture essentially as on disc. Vestiture of rows of erect scales; each scale at base about four times as long as wide, at least eight times as long as wide on declivity, each slightly longer than distance between rows at base, increasing in length toward declivity until about twice as long as distance between rows on declivity, spacing within each row equal to or slightly less than length of scale.

Female.-Similar to male except frons concave from eye to eye, from epistoma to vertex, area above eyes ornamented by a dense brush of long, yellow hair, tips of some setae extending to epistomal margin; scape with a rather large fringe of long hair; anterior margin of pronotum unarmed; elytra 1.6 times as long as wide, declivity confined to posterior third; elytral surface, particularly on declivity, more nearly minutely rugose; elytral scales shorter (about two-thirds as large) and closer.

Distribution.- Puebla.
MEXICO: Puebla: 13 km W Texmelucan, 13-V1-67, $2600 \mathrm{~m}, \mathrm{No} .26$, Phoradendron, S. L. W'ood.

Biology. - Specimens were taken from phloem tissues of dying mistletoe.

Notes.- The above treatment was based on the type series of 11 specimens.

## 26. Pseudothysanoes tumidulus Wood

Pseudothysanoes tumidulus Wood, 1975, Great Basin Nat. 35:28 (Holotype, male; 129 km NE San Juan del Río on Highway 120, Queretaro, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from the distantly allied graniticus Wood by the different female frons, by the smaller elytral scales, and by the very different male declivity as described below.

Male.- Length $1.5-2.0 \mathrm{~mm}, 2.2$ times as long as wide; color very dark brown.

Frons flattened on lower two-thirds, with small concavity on median fifth ascending slightly to epistomal margin, convex above; subshining and almost smooth on flattened area, more coarsely punctate-granulate above; vestiture confined to epistomal area and to convex area.

Pronotum similar to graniticus except anterior margin narrowly rounded and armed by six teeth and posterior areas rather strongly reticulate.

Elytra 1.3 times as long as wide; sides straight and parallel on basal three-fourths, rather abruptly rounded, then broadly rounded behind; striae not impressed, punctures small, moderately deep, spaced by distances equal to diameter of a puncture; interstriae three times as wide as striae, almost smooth, punctures minute, granulate, uniseriate except confused near declivity. Declivity with basal margin abrupt, basically convex except upper half flattened to striae 4, a moderate bulla just below middle from inerstriae 2-4; strial punctures smaller and not as deep as on disc, closer, in indistinct rows, of same size and shape as confused interstrial granules, interstrial punctures obsolete; bulla covered by same surface sculpture as elsewhere. Vestiture of interstrial rows of scales, each slightly longer than wide on disc except scales confused, more abundant, much longer, and more slender at base of declivity; declivity glabrous; rows of fine, recumbent strial hair on disc.

Female.-Similar to male except frons broadly, shallowly concave from epistoma to well above eyes, vestiture on upper area slightly more abundant (less abundant and shorter than in graniticus); anterior margin of pronotum more broadly rounded, unarmed; declivity convex, sculpture as on disc except strial punctures obsolete; rows of interstrial scales continued to apex, each scale equal in length to three-fourths distance between rows, more closely spaced within a row, each about three to four times as long as wide.

Distribution.- Queretaro.
MEXICO: Queretaro: 129 km SE San Juan del Río on Highway 120, 9-VI-71, 2500 m , mistletoe on oak, D. E. Bright.

Notes.- The above treatment was based on the type series of 29 specimens.

# 27. Pseudothysanoes graniticus Wood 

Pseudothysanoes graniticus Wood, 197I, Brigham Young Univ. Sci. Bull., Biol. Ser. $15(3): 21$ (Holotype, female; 43 km SE Nochixtlán, Oaxaca, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from verdicus Wood and viscicolens Wood by the shallowly impressed female frons, with setae on the vertex short, and by the more coarsely granulate male declivital interstriae, with scales on lower half of interstriae 1 smaller.

Female.- Length 1.9 mm (male 1.8 mm ), about 2.7 times as long as wide, color very dark brown.

Frons shallowly concave from epistoma to upper level of eyes, flattened to vertex, surface of concave area smooth, shining, impunctate, finely punctured above, somewhat strigose at sides; epistomal brush conspicuous at sides; flattened area above eyes bearing rather abundant, moderately short, coarse hair. Antennal scape elongate, ornamented by abundant, long hair; club about 2.5 times as long as wide; antenna as long as pronotum.

Pronotum 0.96 times as long as wide; widest at base, sides almost straight, feebly converging on basal half, broadly rounded in front; anterior margin unarmed; summit rather high, at middle; anterior area asperate; posterior area rugose-reticulate, with fine, obscure punctures, fine granules behind summit. Vestiture sparse, of fine and coarse short hair.

Elytra about 1.6 (slightly spread) times as long as wide, 1.8 times as long as pronotum; striae not impressed except 1 weakly, punctures rather small, deep; interstriae slightly less than twice as wide as striae, almost smooth, uniseriately, finely granulate. Declivity convex, steep; interstrial granules slightly larger, confused on 2 and 3. Vestiture of very fine strial hair and rows of erect interstrial scales; each scale on dise three to four times as long as wide on disc, four to five times as long as wide on declivity, each scale slightly longer than distance between scales within a row or between rows.

Male.-Similar to female except stouter, about 2.5 times as long as wide (estimated); frons not visible; pronotum distinctly constricted on anterior half, anterior margin armed by 10 teeth; strial punctures coarser,
interstriae one and one-half times as wide as striae, much more coarsely granulate; elytral scales slightly longer, proportions as on female; scales on lower half of interstriae 1 conspicuously smaller; granules on declivital interstriae 2 and 3 uniseriate.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 43 km SE Nochixtlán, 17-VI-67, No. 55, Phoradendron, S. L. Wood.

Biology.- Specimens were taken from bark of a dying branch of mistletoe.

Notes.- The above treatment was prepared from the holotype and allotype; no other specimens are known.

## 28. Pseudothysanoes verticillus Wood

Pseudothysanoes terticillus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):22 (Holotype, female; 27 km N Ixmiquilpan, Hidalgo, Mexico; Wood Coil.)
Diagnosis. - This species is very closely allied to viscicolens Wood, but it may be distinguished by the more shallowly concave female frons, with a more dense tuft of hair on the vertex, and by the much shorter elytral scales.

Female.- Length $1.6 \mathrm{~mm}, 2.8$ times as long as wide; color almost black, pronotal summit reddish brown.

Frons as in viscicolens except less deeply concave, tuft of hair on vertex slightly shorter, more dense. Antenna and pronotum as in viscicolens.

Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; striae not impressed, punctures rather small, moderately deep; interstriae about twice as wide as striae, punctures uniseriate, finely granulate. Declivity as in graniticus Wood, with indistinct granules and punctures on interstriae 2 and 3 confused. Vestiture of fine, short strial hair, and rows of erect, short, interstrial scales; each scale one to one and one-half times as long as wide, half as long as distance between rows, equal in length to distance betwen scales in a row.

Distribution.- Hidalgo.
MEXICO: Hidalgo: 27 km N Ixmiquilpan, 10-VII-67, 1900 m , probably Phoradendron, S. L. Wood.

Biology.- Presumably due to an error, this specimen was associated with the same field collection number (No. 188) as another series from Acacia. It evidently was taken in
flight and dropped in the vial with the series from Acacia without noting that it represented a different species. Phoradendron was in the area.

Notes.- The above treatment was based on the unique holotype.

## 29. Pseudothysanoes verdicus Wood

Pscudothysanocs terdicus Wood, 1969, Brigham Young Univ. Sci. Bull.. Biol. Ser. 10(2):27 (Holotype. male; 7 km N Tlaxco, Tlaxcala, Mexico; Wood Coll.)
Diagnosis. - This species is allied to ciscicolens, but it is distinguished by the more slender body form, and by other characters included in the above key.

Male.- Length 1.3-1.8 mm, 2.3 times as long as wide; color dark brown, pronotai summit reddish.

Frons convex above, moderately, transversely impressed just above epistoma, with a slight dorsal extension of impression toward center; surface finely rugose; vestiture sparse, rather short, widely distributed.

Pronotum 0.92 times as long as wide; widest at base, sides weakly arcuate and converging on basal three-fifths to a conspicuous constriction, rather narrowly rounded in front; anterior margin armed by four small teeth; summit rather high, behind middle; posterior area coarsely reticulate, with small, sparse, rounded, squamiferous granules; vestiture of intermixed fine, short hair and longer. slender scales.

Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures minute, distinct; interstriae about twice as wide as striae, irregularly marked by lines and obscure points, punctures finely granulate, squamiferous. Declivity confined to posterior third, convex, rather steep; sculpture as on disc except granules smaller, obscure. Vestiture consisting of minute strial hair and rows of erect interstrial scales; each scale on declivity four to five times as long as wide, about equal in length to distance between rows, very slightly shorter on disc.

Female.- Similar to male except frons shallowly concave almost from eye to eye from epistoma to vertex, upper margin ornamented by a dense tuft of long yellow hair, tips of setae reaching slightly bevond middle
of concavity; scape with a small tuft of hair; anterior margin of pronotum unarmed; elytral scales slightly smaller.

Distribution.- Tlaxcala to Oaxaca.
Mexico: Oaxaca: 42 km SE Nochixtlán, $17-\mathrm{Vl}-67$. No. 65, Phoradendron, S. L. Wood. Tlaxcala: $7 \mathrm{~km} N$ Tlaxco, 6-V1-67, 2700 m . No. 24, mistletoe, S. L. Wood.

Host.- Phoradendron spp.
Biology.- Specimens were taken from phloem tissues of dying mistletoe that was growing in Juniperus deppeana at Tlaxco.

Notes.- The above treatment was based on the type series of 65 specimens.

## 30. Pseudothysanoes ciscicolens Wood

Pseudothysanoes tiscicolens Wood, 1969. Brigham Young U'niv. Sci. Bull. Biol. Ser. 10(2):25 (Holotype, male: Zamorano, Morazán. Honduras: Wood Coll.)
Diagnosis.- This species is allied to verdicus Wood, but it may be distinguished by characters summarized in the above key.

Male.- Length 1.3-1.7 mm, 2.2 times as long as wide; color dark brown to black, pronotal summit reddish.

Frons convex, with a feeble impression above epistoma; an obscure subfoveate impression indicated near center; reticulate below, becoming minutely subgranulate above; vestiture sparse, inconspicuous.

Pronotum 0.92 times as long as wide; sides weakly arcuate, converging very slightly on basal two-thirds then broadly rounded in front; anterior margin armed by six small teeth; summit well developed; posterior area minutely rugulose, with sparse, small, subgranulate punctures; vestiture consisting of rather sparse, small, scale- and hairlike setae.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures rather small, deep; interstriae wider than striae, punctures small, uniseriate. Declivity beginning well before middle of elytra, moderately steep, broadly convex; sutural striae only feebly impressed, punctures distinctly larger and deeper than on disc; interstriae narrower, otherwise as on disc. Vestiture consisting of minute strial hair and rows of erect interstrial scales; each scale on disc about twice as long as wide, about twothirds as long as distance between rows; each scale on declivity as wide or slightly wider
than those on disc, and on upper half at least three times longer than those on disc, decreasing in length on interstriae 1 and 2 on lower half to size of scales on disc.

Female.-Similar to male except frons rather deeply concave from epistoma to vertex, concavity clothed with moderately abundant, short, stout setae, upper margin bearing a tuft of long, yellow hair equal in length to half diameter of concavity; anterior margin of pronotum unarmed; declivity confined to posterior third of elytra; strial punctures somewhat reduced; interstrial granules small, regularly placed on dise and declivity; declivity more narrowly convex, sculpture and vestiture as on disc, each scale three to four times as long as wide.

Distribution:- Honduras.
honduras: Zamorano, Morazán, 18-IV-64, 700 m , No. 569, Phoradendron robustissimum, S. L. Wood.

Biology.-Specimens were taken in phloem tissues of dying mistletoe.

Notes.- The above treatment was based on the type series of 16 specimens.

## 31. Pseudothysanoes mucronatus (Wood)

Cryptulocleptus mucronatus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):34 (Holotype, male; La Lima, Cortez, Honduras; Wood Coll.)
Diagnosis.- Although most of the generic characters of Pseudothysanoes clearly fit this species, it is unique in having the elytral apices acuminately extended to form a short mucro, as seen in Micracis or possibly Micracisella. The mucro appears to be a secondary acquisition that should not have a bearing on the generic placement of this species.

Male.- Length $1.2-1.4 \mathrm{~mm}, 2.5$ times as long as wide; color dark reddish brown.

Frons convex, with a feeble impression just above epistoma; surface rather coarsely rugose above, more finely below, with a small, median, smooth area on lower third; vestiture short, sparse. Scape elongate, with fewer than a dozen setae; club broadly oval, unmarked by any indication of sutures.

Pronotum 1.0 times as long as wide; widest two-fifths pronotum length from base, sides weakly arcuate, moderately constricted a fourth of pronotum length behind broadly rounded anterior margin; anterior margin armed by four minute teeth; summit at
middle, moderately high; anterior slope armed by many small asperities; posterior areas rather coarsely reticulate, with moderately abundant, fine, isolated granules behind summit; vestiture of stout, hairlike setae.

Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind except for very short, sutural mucro; striae not impressed, punctures fine, distinct; interstriae minutely subrugose, wider than striae, punctures small, obscure, becoming granulate toward declivity. Declivity convex, very steep; strial punctures larger than on disc but very obscure; interstrial punctures replaced by rather large rounded granules. Vestiture consisting of very fine, moderately long strial hair and rows of erect interstrial scales; scales slightly shorter and more slender on disc; each scale on declivity spaced within and between rows by distances equal to length of scale, each scale about four times as long as wide. Apex with a very short mucro.

Female.- Similar to male except 2.6 times as long as wide; frons less strongly convex, less coarsely rugose, with median fovea near center; anterior margin of pronotum unarmed; elytral scales more slender, at least six times as long as wide on declivity.

Distribution.- Honduras.
HONDURAS: La Lima, Cortez, 5-V-64, 70 m , No. 572, S. L. Wood.

Biology.- Specimens were taken from tunnels in the xylem of stems 1 cm in diameter from a shrubby, woody vine.

Notes.- The above treatment was based on the type series of 46 specimens.

## 32. Pseudothysanoes cuspidis Wood

Pseudothysanoes cuspidis Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):22 (Holotype, female; 10 kmi NE Teziutlán, Puebla, Mexico; Wood Coll.)
Diagnosis.- This species is allied to subulatus Wood and spicatus Wood, but it may be distinguished by the smaller size, by the flattened and grooved female frons, by the coarser punctures on the elytral declivity, and by the slender, rather long elytral setae.

Female.- Length $1.2-1.4 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown.

Frons transversely flattened, longitudinally concave from epistoma to upper level of eyes, median line narrowly sulcate from level of antennal insertion to upper level of eyes; surface smooth and shining on epistomal area, then finely substrigose, becoming more coarsely reticulate-granulate above eyes; vestiture sparse, fine, inconspicuous. Antennal scape elongate; club moderately large, sutures very obscure.

Pronotum 1.0 times as long as wide; sides feebly arcute, subparallel on basal half, distinctly constricted on anterior half, broadly rounded in front; summit at middle, moderately high; sparsely asperate on anterior slope; finely rugose-reticulate behind, a few minute gramules. Vestiture of sparse hair.

Elytra 1.8 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel on more than basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures small, shallow; interstriae not smooth, less than twice as wide as striae, punctures fine, obscured by surface sculpture. Declivity convex, steep; interstriae uniseriately, finely granulate. Vestiture of rows of very fine strial hair and rows of slightly longer, coarser, interstrial setae, not at all scalelike; interstrial setae about as long as distance between rows. Last visible sternum narrowly produced to form a mucronate process.

Distribution.- Puebla.
MEXICO: Puebla: 10 km NE Teziutlán, 2-V11-67, 1600 m , No. 144, S. L. Wood.

Biology.- Specimens were taken from the cambium region of a tree branch 3 cm in diameter. The biramous parental tumnels paralleled the grain of the wood. The species is bigamous. Females pack the egg tumnels with frass as they progress; males evidently leave the nuptial chamber soon after the females begin the egg galleries. A sample of the host tree has not yet been identified.

Notes.- The above treatment was based on the type series of 14 female specimens.

## 33. Pseudothysanoes subulatus (Wood)

Cryptulocleptus subulatus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 34$ (Holotype, male; Volcán Pacaya, Esquintla, Guatemala; Wood Coll.)

Diagnosis. - This species, cuspidis Wood, and spicatus Wood form a unique group in the genus in which the last visible tergum of the male and the last visible sternum of the female form a mucro that projects beyond the elytral apex. This species is distinguished from the closely related spicatus as indicated in the above key.

Male.- Length $1.3-1.7 \mathrm{~mm}, 2.3$ times as long as wide; color very dark brown to black, pronotal summit reddish brown.

Frons and pronotum as in spicatus except part of pronotal vestiture stout.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; outline as in spicatus; striae not impressed, punctures rather large, deep, sharply impressed; interstriae almost smooth, shining, one and one-half times as wide as striae, uniseriate punctures finely granulate. Declivity steep, convex; striae very feebly impressed, punctures more obscure. Vestiture consisting of short, fine strial hair (some flattened on declivity), and rows of longer, interstrial scales; each scale slightly more than half as long as distance between rows, separated within rows by distances equal to length of scale, each about twice as long as wide. Tergal mucro about as in spicatus.

Female. - Similar to male except 2.6 times as long as wide; frons rather deeply concave on median three-fourths from epistoma to vertex, a small, smooth, median area on lower half, most females ornamented by a small, sparse tuft of hair at upper margin of concavity; anterior margin of pronotum unarmed; strial punctures not as deep, perhaps smaller, interstrial scales very slightly longer and more slender, each scale about four times as long as wide; tergal mucro replaced by sternal mucro as in spicatus.

Distribution.-Guatemala.
guatemala: Volcán Pacaya, 1-V1-64, 1300 m , No. 700, Caldo de Frijol, S. L. Wood.

Host.- Possibly Eschweilera sp.
Biology. - Specimens were taken from the phloem of branches less than 8 cm in diameter of a recently cut tree known locally as Caldo de Frijol.

Notes.- The above treatment was based on the type series of 59 specimens.

# 34. Pseudothysanoes spicatus (Wood) 

Cryptulocleptus spicatus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):33 (Holotype, male; Cerro Punta, Chiriquí, Panama; Wood Coll.)
Diagnosis.- This species is distinguished from subulatus by characters summarized in the above key.

Male.- Length $1.5-1.8 \mathrm{~mm}, 2.4$ times as long as wide; color dark brown, summit of pronotum reddish brown.

Frons convex above, becoming more nearly flattened on lower third; surface ru-gose-reticulate and obscurely punctured; an indefinite, median, subfoveate impression just below upper level of eyes; vestiture fine, short, inconspicuous, except long and conspicuous along epistomal margin. Scape elongate.

Pronotum 0.90 times as long as wide; widest a third of pronotum length from base, sides arcuate, a weak constriction on anterior third, rather broadly rounded in front; anterior margin armed by about eight small teeth; summit just behind middle, moderately high; asperities on anterior slope rather large; posterior area rugose-reticulate, a few fine granules behind summit. Vestiture hairlike.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures very small, obscure; interstriae almost twice as wide as striae, very finely rugose, punctures very fine, their anterior margins very finely granulate. Declivity convex, steep; sculpture essentially as on disc. Vestiture consisting of fine, moderately long strial hair and rows of slightly longer interstrial bristles; each bristle about two-thirds as long as distance separating rows, separated within rows by distances equal to length of bristle, bristles becoming scalelike on declivity, each scale there at least three times as long as wide. Last visible tergum narrowly produced into a mucrolike process that projects beyond elytral apex.

Female.- Similar to male except 2.6 times as long as wide; frons shallowly concave to vertex, lower, median half smooth, shining, and ascending toward epistomal margin; anterior margin of pronotum unarmed; interstrial setae on disc fine, hairlike, bristlelike
on declivity; mucro formed by last visible sternum; last tergum rounded on posterior margin.

Distribution.- Panama.
PANAMA: Cerro Punta, Chiriquí, 11-1-64, 1800 m , No. 382, S. L. Wood.

Biology.- Specimens were taken from tunnels in the cambium region of a $\log 1 \mathrm{~m}$ in diameter. The galleries tended to be longitudinal.

Notes.- The above treatment was based on the type series of 50 specimens.

## 35. Pseudothysanoes plumalis Wood

Pseudothysanoes plumalis Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):29 (Holotype, male; 18 km N Huajuapan, Oaxaca, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from coracinus Wood by characters summarized in the above key.

Male.- Length $1.4-1.7 \mathrm{~mm}, 2.4$ times as long as wide; color dark brown.

Frons shallowly concave almost to upper level of eyes, convex above; surface rugosereticulate, with a few fine granules in convex area; vestiture sparse, inconspicuous. Scape with fewer than a dozen setae.

Pronotum 0.91 times as long as wide; outline as in verdicus; posterior area reticulate, very fine punctures obscure; vestiture of fine and stout hairlike setae.

Elytra 1.4 times as long as wide, 1.65 times as long as pronotum; sides straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures rather coarse, deep; interstriae narrower than striae, almost smooth, punctures very fine, uniseriate. Declivity largely confined to posterior third, convex, steep; strial punctures greatly reduced, interstrial punctures very finely granulate. Vestiture consisting of rows of small, erect, interstrial scales of about equal size on disc and declivity; each scale about three times as long as wide, about onehalf as long as distance between rows of scales, spaced within rows by distances equal to about three times length of a scale.

Female.-Similar to male except frons more broadly, somewhat more deeply concave; scape bearing a large, dense tuft of long, yellow hair; pronotum armed by two teeth on anterior margin; declivity slightly
shorter and steeper; declivital interstrial granules obsolete.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 18 km N Huajuapan, 15-V1-67. $2000 \mathrm{~mm}, \mathrm{No} .43$. Psittacanthus, S. L. Wood.

Brology.- Specimens of this species were taken from phloem tissues of the abovenamed mistletoe.

Notes. - The above treatment was based on the type series of 12 specimens.

## 36. Pseudothysanoes coracinus Wood

Pseudothysanoes coracinus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):29 (Holotype, male; 34 km N Juchitlán, Jalisco, Mexico; Wood Coll.)
Diagnosis.- The male of this species is distinguished from hopkinsi Blackman by the more nearly flattened frons, by the more weakly impressed strial punctures, and by the much broader interstrial scales.

Male.- Length 1.2-1.3 mm, 2.2 times as long as wide; color almost black, pronotal summit reddish.

Frons convex above, weakly, transversely impressed just above epistoma, with a narrow impression extending dorsad to center of frons; surface rugose-reticulate; vestiture sparse, consisting of coarse, subplumose setae of moderate length.

Pronotum 0.84 times as long as wide; widest a third of pronotum length from base, sides rather strongly arcuate on basal twothirds, then weakly constricted before rather broadly rounded anterior margin; anterior margin armed by four broad, low teeth; summit high, behind middle; posterior area reticulate, punctures sparse, minute, obscure; vestiture of stout and slender, short, hairlike setae.

Elytra 1.3 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, rather narrowly rounded behind; striae not impressed, punctures rather small, distinct but not deep; interstriae about as wide as striae, punctures uniseriate, finely granulate. Declivity on slightly less than posterior half, convex, rather steep; as on disc except strial punctures slightly smaller, interstrial granules very slightly higher. Vestiture consisting of minute, fine, strial hair and rows of erect
interstrial scales; each scale about twice as long as wide; not longer on declivity.

Distribution.- Jalisco.
MEXICO: Jalisco: 34 km N Juchitlán, 3-VII-65. 1300 m, No. 182a, S. L. Wood.

Biology:- Specimens were taken from the cambium region in twigs of an midentified tree.

Notes.- The above treatment was based on the type series of four male specimens.

## 37. Pseudothysanoes tenellus Wood

Psendothysanves tenellus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):23 (Holotype. male: 33 km Whorelia, Michoacán, Mexico: Wood Coll.)
Diagnosis.- This species is distinguished from hopkinsi Blackman by the very elongate interstrial scales on the male declivity and by the flattened frons with a feeble central impression in both sexes.

Male.- Length $1.3-1.6 \mathrm{~mm}, 2.4$ times as long as wide; color almost black.

Frons almost flat from transverse impression just above epistoma to upper level of eyes, convex above, a small median impression at upper level of eyes; smooth and shining near median line, becoming rugosereticulate in lateral areas, rugose-punctate above eyes; vestiture of sparse, coarse setae. Scape elongate, slender; club longer than scape, broadly oval, two sutures clearly marked, rather strongly procurved.

Pronotum 1.0 times as long as wide; widest at base, sides strongly arcuate, very strongly constricted on anterior half, rather narrowly rounded in front; anterior margin armed by six coarse teeth; summit behind middle, asperate on anterior slope; reticulate-granulate in posterior area, with sparse, fine, obscure punctures, a few granules behind summit. Vestiture of sparse, short, stout setae.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, obtusely angulate behind; striae not impressed, punctures moderately large, deep; interstriae slightly wider than striae, almost smooth, uniseriately, coarsely granulate on posterior third, punctures feebly to not at all granulate to base. Declivity broadly convex, rather steep; striae weakly impressed on upper two-
thirds, punctures smaller; uniseriate interstrial granules rather coarse at base, decreasing in size posteriorly on upper two-thirds, almost obsolete below. Vestiture consisting of rows of interstrial scales, short on disc, each about three times as long as wide, increasing in length toward declivity, very long and delicate on declivity, some about four times as long as distance between rows.

Female.- Similar to male except frons more extensively flattened, more finely sculptured; pronotum similarly, almost equally armed; interstrial granules slightly smaller; declivital scales little longer than those on disc, each about three times as long as wide, those on interstriae 1 and 2 smaller.

Distribution.- Michoacán.
Mexico: Michoacán: 33 km W Morelia, 16 -VI-65, 2300 m, No. 64, Phoradendron, S. L. Wood; Patzcuaro km 32, 31-X-80, S-130, Psittacanthus, T. H. Atkinson.

Biology.- Specimens were taken from phloem tissues in dying branches of mistletoe.

Notes. - The above treatment was based on the type series of 19 specimens and on 5 other specimens.

## 38. Pseudothysanoes yuccavorus Wood

Pseudothysanoes yuccavorus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):23 (Holotype, male; 15 km W Durango, Durango, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from hopkinsi Blackman by the flattened frons with the absence of a central fovea, by the smaller, more slender antennal club, and by the shorter, stouter interstrial scales.

Male.- Length $1.1-1.3 \mathrm{~mm}, 2.2$ (female 2.5) times as long as wide; color black.

Frons weakly convex, almost flat to upper level of eyes, a weak transverse impression just above epistoma; epistoma shining, remaining area rather coarsely reticulategranulate, punctures fine, obscure; vestiture of sparse, short, coarse setae. Antennal scape elongate, slender; club small, 1.6 (female 1.8) times as long as wide, sutures very obscure, weakly procurved.

Pronotum 0.92 times as long as wide; subtriangular, widest at base, sides weakly arcuate, converging toward narrowly rounded anterior margin; anterior margin armed by four coarse teeth; summit high, narrow; anterior area coarsely asperate; posterior area
rugulose, a few fine granules behind summit; vestiture of sparse, coarse setae of moderate length.

Elytra 1.3 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on slightly more than basal twothirds, rather broadly rounded behind; striae not impressed, punctures small, moderately deep; interstriae twice as wide as striae, almost smooth, uniseriately, rather coarsely granulate. Declivity rather steep, convex; as on disc. Vestiture consisting of minute, fine strial hair, and erect, interstrial scales; each scale three times as long as wide, separated between rows and within a row by distances slightly greater than length of a scale.

Female. - Similar to male except body form more slender; antennal club longer; anterior margin of pronotum more broadly rounded, unarmed; interstrial granules almost obsolete on disc; interstrial scales slightly longer, very slender, each eight or more times as long as wide.

Distribution.- Durango.
MEXICO: Durango: $15 \mathrm{~km} W$ Durango, 4-VI-65, 1300 m , No. 1, Yucca leaves, S. L. Wood.

Biology.- Specimens were taken from dying leaves of a large, healthy, branching Yucca. The parental galleries apparently were biramous and transverse.

Notes.- The above treatment was based on the type series of 47 specimens.

## 39. Pseudothysanoes hopkinsi Blackman

Psudothysanoes hopkinsi Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Bull. 25:200 (Holotype. male; Piru Ck., Ventura Co., California; U.S. Nat. Mus., 27140)

Diagnosis.- This species is distinguished from yuccavorus Wood and rigidus (LeConte) by characters summarized in the above key.

Male.- Length $1.3-1.5 \mathrm{~mm}, 2.3$ (female 2.5) times as long as wide; color black.

Frons flattened to very shallowly concave, with a very large, deep, central fovea; otherwise as in yuccavorus. Antennal club 1.3 times as long as wide. Pronotum essentially as in yuccavorus except posterior area more brightly shining, less coarsely rugulose, with punctures clearly evident.

Elytra as in yuccavorus except strial punctures larger, interstriae as wide as striae;
interstrial scales each about four to six times as long as wide, spaced between rows and within rows by distances slightly less than length of a scale.

Female.- Similar to male except body more slender; frons narrowly, deeply concave on lower half; teeth on anterior margin of pronotum reduced in size and number.

Distribution.-S California.
USA: California: Big Pines Pk., Los Angeles Co., I8-IV-40, Fremontia californica: $3 \mathrm{~km}(2$ miles) E California Hot Springs, XII-6S, IS-IN-40, F. californica, H. B. Leech; Piru Ck., Ventura Co., 4-VI-04, Hopk. US 2782, Salix: San Bernardino Co.: Sequoia N.P., 19-IV-34. Hopk. US 21069, Fremontia; Tejon Pass near Lebec, Ventura Co., 4000 ft , Fremontia.

Host.- Fremontia californica.
Biology. - Except for host preference nothing on the habits of this species has been reported.

Notes.- The above treatment was based on the holotype and on 125 other specimens.

## 40. Pseudothysanoes rigidus (LeConte)

Fig. 143

Cryphalus rigidus LeConte, 1876. Proc. Amer. Philos. Soc. 15:362 (Lectotype, male: Canada: Mus. Comp. Zool., 103 I present designation)
Pseudothysanoes drakei Blackman, 1920, Mississippi Agric. Expt. Sta. Tech. Bull. 9:48 (Lectotype. male: Syracuse, New York; U.S. Nat. Mus., 24746, present designation); Wood, 1957, Canadian Ent. 89:402. Synonymy
Diagnosis.- This species is distinguished from hopkinsi Blackman by characters summarized in the above key.

Male.- Length 1.3-1.6 mm, 2.2 (female 2.4) times as long as wide; color very dark brown, almost black, pronotal summit reddish brown.

Frons as in hopkinsi. Pronotum about as in hopkinsi except anterior area broader, posterior area more finely sculptured, subreticulate, punctures very fine.

Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures small, distinct; interstriae wider than striae, smooth, punctures fine, uniseriate, not at all granulate. Declivity convex, moderately steep; striae very feebly impressed; interstriae weakly convex, punctures not granulate. Vestiture of fine, short, strial hair, and interstrial rows of erect scales; each scale on declivity about four times as long
as wide, slightly longer than distance between scales between rows or within a row.

Female.-Similar to male except more slender; frons shallowly, broadly concave from epistoma to upper level of eyes, deeply, narrowly impressed at center of lower half; anterior margin of pronotum unarmed; elytral scales very slightly shorter; interstrial punctures on dise and declivity feebly granulate.

Distribution.- Ontario to Kansas and Pennsylvania.

CANADA: "Canada" (presumably southern Ontario), G. H. Horn. USA: Kansas: Lawrence, 5, 7-IN-50, Tilia americana, S. L. Wood. Michigan: Detroit, VI, Hopk. W. Va. 7599c, Hubbard and Schwarz. New York: Syracuse, 6-X-20, basswood, C. J. Drake. Ohio: Deshler, Hopk. US 2301, Tilia, A. D. Hopkins. Peunsylvania: Clark's Valley, 20-III, Tilia americana, J. N. Knull; Dauphin, 10-I, J. N. Knull.

Host.- Tilia americana.
Biology. - Hundreds of specimens were reared from recently cut branches about 3-8 cm in diameter at Lawrence, Kansas. Parental galleries were biramous and transverse. Larval mines tended to follow the grain of the wood, but were entirely within the bark.

Notes. - The above treatment was based on the three syntypes of rigidus, on 15 paratypes of drakei, and on 263 other specimens.

Because a lectotype has not formally been designated, I here designate the first specimen in the LeConte series, a male, previously regarded as the type and bearing the label Type 1031, as the lectotype of Cryphalus rigidus LeConte. Although Blackman's description of drakei was based almost exclusively on a particular male, he indicates his species was based on a (syntypic) series of 59 specimens. Because of the ambiguity and to avoid future problems, I here designate the male in the U.S. National Museum from Blackman's series that has been labeled as the holotype, and recognized as such by all who have dealt with this species, as the lectotype of Pseudothysanoes drakei Blackman.

## 41. Pseudothysanoes arbuti (Wood)

Cryptulocleptus arbuti Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 30$ (Holotype, male: 13 km W Texmelucan, Puebla, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from caritus Wood by characters summarized in the above key.

Male.-Length $1.0-1.3 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown.

Frons convex above, narrowly, rather strongly, transversely impressed just above epistoma, impression extending slightly dorsad at center; vestiture confined to epistomal margin. Scape twice as long as pedicel, bearing about six setae; club oval, very slightly longer than wide.

Pronotum 0.94 times as long as wide; essentially as in quercinus except posterior area minutely rugose-reticulate, most of punctures minutely granulate.

Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; outline about as in quercinus; striae not impressed, punctures rather coarse, close, not sharply impressed; interstriae as wide as striae, minutely irregular, punctures very fine, uniseriate. Declivity steep, convex; strial punctures slightly reduced in size, interstrial punctures minutely granulate. Vestiture consisting of very fine, moderately long strial hair and slightly longer, erect interstrial scales; each scale slender, equal in length to distance between rows, slightly closer within each row, each at least eight times as long as wide.

Female.- Similar to male except 3.0 times as long as wide; upper frons bearing rather abundant short, stout setae; scape bearing about a dozen setae; anterior margin of pronotum unarmed; elytral scales a little more slender.

Distribution.- Puebla.
MEXICO: Puebla: 13 km W Texmelucan, 13 -VI- 67 , 2600 m , No. 27 , Arbutus, S. L. Wood.

Brology.- Specimens were taken from small twigs.

Notes.- The above treatment was based on the type series of 36 specimens.

## 42. Pseudothysanoes caritus (Wood)

Cryptulocleptus caritus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):30 (Holotype, male; Cerro Punta, Chiriqui, Panama; Wood Coll.)
Diagnosis.- This species is distinguished from arbuti Wood by the less strongly convex frons that lacks a transverse impression, by the smaller, less abundant, pronotal asperities, and by the very different pronotal and elytral vestiture.

Male.- Length $1.2-1.3 \mathrm{~mm}, 2.7$ times as long as wide; color dark brown.

Frons convex to epistomal margin, a moderately large fovea just below center; surface reticulate in marginal areas, smooth and shining on middle half, with a few scattered, small, punctures; vestiture inconspicuous. Scape elongate; club small, oval.

Pronotum 1.0 times as long as wide; widest near base, sides very weakly arcuate, converging slightly to shallow constriction onethird pronotum length from rather narrowly rounded anterior margin; anterior margin armed by four moderately large teeth; summit at middle, moderately high; anterior slope with fine asperities; posterior area minutely rugose, minute punctures obscure; vestiture slender, hairlike in both asperate and posterior areas.

Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; outline as in quercinus; striae not impressed, punctures fine; interstriae as wide as striae, with abundant, very minute points, punctures very fine, obscure. Declivity steep, convex, as on disc except interstrial punctures finely granulate. Vestiture consisting of very fine long, strial hair and erect interstrial setae; each interstrial seta on disc stout, hairlike, one and one-half times as long as strial hair, slightly longer than distance between rows, more closely spaced within each row; interstrial setae becoming scalelike on declivity and very slightly longer, each scale at least six times as long as wide.

Female.- Similar to male except 2.9 times as long as wide; frons very weakly, transversely impressed just above epistomal margin; anterior margin of pronotum unarmed; interstrial granules on declivity very minute; interstrial setae on declivity stout but essentially hairlike.

Distribution.- Panama.
PANAMA: Cerro Punta, Chiriquí, 11-I-64, 1800 m , No. 411, S. L. Wood

Brology.- This species was taken from phloem tissues in broken branches of an unidentified tree.

Notes.- The above treatment was based on the type series of 12 specimens.

## 43. Pseudothysanoes crassinus Wood

Pseudothysanoes crassinus Wood, 1969, Brigham Young Sci. Bull., Biol. Ser. 10(2):29 (Holotype, male; 24 km W Tehuantepec, Oaxaca, Mexico; Wood Coll.)

Diagnosis.- This species is allied to frondicolens Wood, but it may be distinguished by characters mentioned in the above key.

Male.- Length $0.8-1.0 \mathrm{~mm}$ (female $1.0-1.2 \mathrm{~mm}$ ), 2.0 (female 2.4) times as long as wide; color black.

Frons and pronotum as in coracinus Wood except teeth on anterior margin of pronotum more slender, summit higher and wider, and posterior areas obscurely reticulate.

Elytra 1.1 times as long as wide, 1.25 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind; striae not impressed, punctures obsolete; interstriae each with a uniseriate row of large tubercles, increasing in size toward declivity. Declivity beginning at middle, rather steep, convex; a few minute strial punctures obscurely indicated; interstrial granules greatly reduced on upper half, obsolete on lower half and replaced by very minute, obscure punctures. Vestiture consisting of fine, moderately long, suberect, strial hair and interstrial rows of longer, erect scales; each scale about four times as long as wide on disc, six times as long as wide on declivity; each scale as long as distance between rows on disc, slightly longer on declivity, spaced within rows by a slightly greater distance.

Female.- Similar to male except larger; 2.4 times as long as wide; frontal impression very slightly larger; anterior margin of pronotum unarmed; strial punctures obscurely visible; interstrial granules obsolete; declivity confined to posterior third of elytra, more narrowly convex; interstrial scales slender, at least eight times as long as wide.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 24 km W Tehuantepec. 22-VI-67, 70 m , No. 35. S. L. Wood.

Biology.- Specimens were taken from the cambium region of the bole of a small, dying, thornless leguminous tree having bipinnately compound leaves.

Notes.- The above treatment was based on the type series of 65 specimens.

## 44. Pseudothysanoes frondicolens Wood

Pseudothysanoes frondicolens Wood, 1971, Great Basin Nat. 31:73 (Holotype, male; Herb Martyr Campground, Chiricahua Mts., Arizona; Wood Coll.)
Diagnosis.- This species is distinguished from crassinus Wood by the absence of
interstrial granules in the male, by the impressed female frons, by the finer pronotal sculpture, and by the less abundant elytral vestiture.

Male.- Length $0.8-1.0 \mathrm{~mm}$ (female $1.0-1.2 \mathrm{~mm}$ ), 2.1 (female 2.3) times as long as wide; color rather dark brown.

Frons flattened on lower third, convex above, with a conspicuously impressed median fovea; surface rather obscurely reticulate-granulate below, coarser above; vestiture of sparse, coarse hair. Antennal scape long, slender; club small, oval, sutures not indicated.

Pronotum 0.90 times as long as wide; subtriangular, widest near base, sides arcuately converging to narrowly rounded anterior margin, armed by two coarse, median teeth (four teeth present in some specimens); summit slightly behind middle, rather high and narrow; anterior slope rather coarsely asperate; posterior area very finely sculptured, almost smooth, sparse minute punctures. Vestiture sparse, short, rather fine.

Elytra 1.3 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind; surface usually covered by an incrustation; striae not impressed, punctures moderately coarse, rather shallow, not close; interstriae as wide as striae, evidently smooth, punctures fine, not at all granulate. Declivity occupying slightly more than posterior third, very broadly convex, rather steep; strial punctures larger than on disc; interstriae not at all granulate; somewhat flattened between interstriae 3, with suture feebly elevated on upper half. Vestiture of rows of fine, short strial hair, and rows of longer, erect interstrial scales; scales sparse, widely, irregularly spaced, each about four times as long as wide, curved toward elytral apex on apical part; declivital interstriae 3 usually devoid of scales, 1 often with only one, 3 and 4 each with about three to five scales.

Female.- Similar to male except body form more slender; frons irregularly concave on rather narrow triangular area from epistoma to vertex; anterior margin of pronotum armed as in male; strial punctures finer; elytral scales more slender, each about six
times as long as wide, sparse but more regularly placed.

Distribution.-S Arizona.
USA: Arizona: Herb Martyr Campground, Chiricahua Mtts, 7 -Vll-69, $1900 \mathrm{~m}, \mathrm{No} .75$, Yucca, S. L. Wood.

Biology.- This species breeds in the dying lower leaves of living plants about $2-3 \mathrm{~m}$ in height. The parental galleries were in the form of a transverse "H," apparently with two short egg tunnels formed by each of two females. The straight larval mines were constructed longitudinally between the fibers.

Notes. - The above treatment was based on the type series of 156 specimens.

## 45. Pseudothysanoes contrarius Wood

Pseudothysanoes contrarius Wood, 197., Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):14 (Holotype, male; Lagos de Colores, Chiapas, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from bartoni Bruck by the more slender, recurved spines on the male declivital interstriae $2,3,5$, and 7 , by the coarser strial punctures, by the broader interstrial scales, and by the more broadly rounded anterior margin of the pronotum.

Male.- Length $1.0-1.2 \mathrm{~mm}, 2.1$ times as long as wide; color black.

Frons convex, a weak transverse impression on lower half, subfoveate at center; surface rugose-reticulate, punctures not evident; vestiture confined to epistomal brush.

Pronotum 0.89 times as long as wide; widest near base, sides moderately arcuate, converging toward rather broadly rounded anterior margin; anterior margin armed by 10 small denticles. Vestiture of sparse, short, stout bristles, a few small scales in lateral area.

Elytra 1.3 times as long as wide; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures coarse, deep; interstriae as wide as striae, smooth, shining, with uniseriate rows of small granules. Declivity convex, gradual, beginning at middle of elytra; strial punctures gradually reduced in size until minute near apex; granules on interstriae 1 smaller than on dise, obsolete on 2 except one or two near base enlarged into slender, sharply pointed, recurved spines, 3 with seven to nine similar spines, 5 with three, and 7
with about five spines; spines on 3 slightly recurved, longest spines equal in length to width of an interstriae, slightly shorter than interstrial scales. Vestiture of rows of minute, fine, interstrial hair, and rows of erect, interstrial scales; each scale about two-thirds as long as distance between rows, about three to four times as long as wide, those arising from posterior surface of spines often slightly larger.

Distribution.- Chiapas.
MEXICO: Chiapas: Lagos de Colores, 14-VI-69, Acacia, D. E. Bright.

Notes.- The above treatment was based on the type series of four specimens.

## 46. Pseudothysanoes bartoni Bruck

Pseudothysanoes bartoni Bruck, 1936, Bull. S. Califormia Acad. Sci. 35:32 (Holotype, male; Saddle Peak, Santa Monica Mts., California; Ohio State Univ. Coll.)
Diagnosis.- This species, contrarius Wood, and multispinatus Wood are the only species in the genus in which male declivital interstriae 3 and 5 are armed by long, slender, sharply pointed spines. This species is distinguished from contrarius and multispinatus by characters summarized in the above key.

Male.- Length 1.2-1.4 mm, 2.3 times as long as wide; color black.

Frons convex, rather weakly, transversely impressed above epistoma; surface almost smooth below impression, rather coarsely granulate-punctate above; vestiture of moderately abundant, coarse setae of moderate length. Antennal scape slender, elongate; club moderately large, oval, sutures obscurely indicated.

Pronotum 0.95 times as long as wide; subtriangular, widest at base, sides arcuately converging toward very narrowly rounded anterior margin; anterior margin armed by four teeth, median pair longer; summit at middle; anterior slope asperate; posterior area shining, finely punctured, surface irregular but not rugulose. Vestiture rather sparse, short, stout.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures rather small, deep; interstriae as wide as
striae, almost smooth, punctures fine, becoming granulate near declivity. Declivity confined to posterior third, convex, rather steep; about as on disc except interstrial granules very fine, interstriae 3 armed by two moderately large, slender, pointed spines, one at declivital base, othre spine two-fifths declivital length from base; interstriae 5 and 7 each with one similar spine just below declivital base. Vestiture of rows of short, fine, strial hair, and rows of interstrial scales; each scale rather slender, six or more times as long as wide at base of declivity, slightly shorter on disc and declivity.

Female.-Similar to male except more slender; frons more broadly flattened, with a deep, shining, oval concavity on median third at and just above level of antennal insertion; pronotum more broadly rounded in front, anterior margin usually unarmed; elytral declivity devoid of spines.

Distribution.-S California.
USA: California: Saddle Peak, Santa Monica Mts., I6-XII-33, Maluastrum thurberi, C. R. Bruck; Wentwood Hills, Los Angeles Co., 26-II-35, 25-VI-39, 1,6-1X-40, Malcastrum, A. T. McClay.

Host.-Sphaeralcea fasciculata.
Biology.- Unknown except for the host association.

Notes.- The above treatment was based on the holotype, allotype, 22 paratypes, and 37 other specimens.

## 47. Pseudothysanoes multispinatus Wood

 Fig. 154Pseudothysanoes multispinatus Wood, 1957, Great Basin Nat. 17:109 (Holotype, male: Gainseville, Florida: U.S. Nat. Mus., 71622)
Diagnosis.- This species is distinguished from bartoni Bruck by the discal interstriae being narrower than the striae, with punctures finely granulate, by the spines on the male declivital interstriae 1,3 , and 5 , and by the more extensively impressed female frons.

Male.- Length $1.2-1.4 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown.

Frons somewhat flattened below, with median third on lower half abruptly, deeply concave, epistomal area elevated; surface granulate-punctate above, almost smooth and shining on epistoma and in concavity; vestiture of rather sparse, coarse setae. Antennal scape long, slender; club rather large, oval, sutures obscure.

Pronotum 0.91 times as long as wide; basically as bartoni except more broadly rounded in front.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; outline as in bartoni; striae feebly impressed, punctures coarse, rather deep; interstriae narrower than striae, uniseriately, subcrenulately granulate. Declivity occupying slightly more than posterior third, convex, moderately steep; about as on disc except interstriae 1,3 , and 5 each armed by one to three long slender spines on upper half, those on 3 usually longer. Vestiture consisting of rows of fine, short, strial hair, and rows of erect, interstrial scales; each scale about three times as long as wide at base of declivity, shorter on disc and lower half of declivity, much longer on upper half of declivity.

Female.- Similar to male except frons more broadly impressed exclusive of median excavation on lower half; anterior margin of pronotum usually unarmed; elytral spines absent; interstrial scales of uniform length, each about four times as long as wide.

Distribution.-Florida.
USA: Florida: Gainesville, IT-I-39, No. 8570, Tilia cienserrata, A. N. Tissot; Alahua Co., 21-IV-76, Tilia, T. H. Atkinson.

Host.- Tilia cienserrata.
Biology. - Unknown except for the host association.

Notes.- The above treatment was based on the type series of 43 specimens.

## 48. Pseudothysanoes acacicolens Wood

Pseudothysanoes acaricolens. Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):23 (Holotype, male; Playa del Coco, Guanacaste, Costa Rica, Wood Coll.)
Diagnosis.- This species is distinguished from spinatus Wood in the male by the much smaller declivital spines and by the unaltered sculpture and vestiture of the elytral declivity, both being essentially continuous with that of the disc. In the female the pronotum is more coarsely reticulate and the elytral declivity more coarsely punctured than in spinatus, evidently with very fine granules on interstriae 3.

Male.- Length $1.0-1.2 \mathrm{~mm}$ (female 1.1-1.3 mm), 2.4 times as long as wide; color light brown.

Frons convex above, transversely impressed above epistoma; surface coarsely reticulate; vestiture consisting of scattered, rather short, subplumose hair.

Pronotum 1.0 times as long as wide; subcircular, with a slight constriction on anterior half; anterior margin armed by six irregular teeth; summit at middle, high; coarsely asperate in front; posterior area rather coarsely reticulate, punctures fine, inconspicuous; vestiture rather abundant, consisting of suberect slender scales and shorter hair intermixed.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly, evenly rounded behind; striae not impressed, punctures moderately large, rather deep; interstriae as wide as striae, 1 and to a lesser extent 5 bearing a uniseriate row of moderately large, low tubercles, punctures on other interstriae weakly if at all granulate. Declivity convex, very slightly flattened on upper half; striae as on disc but evidently somewhat narrower; interstriae 2 bearing a slender spine at upper margin of declivity, and a similar spine one-fourth of declivital length from upper margin; spines similar in position and shape to those of spinatus but only half as long; interstriae 5 bearing two similar but smaller spines, one just above and one just below level of lower spine on interstriae 2 ; granules on 2 and 5 not continued below lower spine on each interstriae. Vestiture consisting of fine strial hair and interstrial scales; each scale about four times as long as wide on disc and sides, somewhat shorter on striae 1-3 on lower two-thirds of declivity.

Female.- Similar to male except larger, more slender; frons a little less strongly convex; anterior margin of pronotum unarmed; declivity more strongly convex, unarmed; elytral scales more slender, somewhat shorter and narrower on declivity.

Distribution.- Costa Rica.
COSTA RICA: Playa del Coco, Guanacaste, 21-111-63, 10 m, No. 236, Acacia, S. L. Wood.

Biology. - Specimens were taken from the cambium region in the bole and larger limbs of a dying Acacia tree (a species having slender thorns).

Notes.- The above treatment was based on the type series of 68 specimens.

## 49. Pseudothysanoes spinatus Wood

Fig. 145

Pseudothysanoes spinatus Wood, 1956, Canadian Ent. 88:154 (Holotype, male; 27 km W Tehuantepec, Oaxaca, Mexico; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This distinctive species is distinguished from acacicolens Wood by characters summarized in the above key.

Male. - Length 0.9-1.1 mm (female 1.1-1.3 mm), 2.4 (female 2.5) times as long as wide; color yellowish brown.

Frons convex, transversely impressed just above epistoma; surface finely granulate, finer toward epistoma; vestiture of sparse, coarse, short setae. Antennal scape long, slender; club moderately small, oval, devoid of sutures.

Pronotum 0.90 times as long as wide; widest near base, sides arcuate, converging very slightly on basal half, rather narrowly rounded in front; anterior margin armed by four teeth; summit at middle, rather high; anterior slope asperate; posterior area shining, obscurely reticulate, finely, sparsely punctured. Vestiture of short, sparse, broad scales on disc, a few short bristles at sides and on asperate area.

Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures rather small, deep; interstriae as wide as striae, smooth, punctures minute, granulate near declivity. Declivity occupying posterior half of elytra, gradual, broadly convex; striae about as on disc, interstriae narrower; interstriae 2-6 each with a granule at base of declivity, 2 with one large, slender spine at base of declivity, another just above middle of declivity, length of each spine equal to combined width of interstriae 1 and 2; interstriae 5 and 6 each with one slightly smaller spine at margin of declivity. Vestiture on disc of rows of fine, short strial hair, and rows of erect, interstrial scales; each scale about two to four times as long as wide; scales on declivity very small, if present.

Female.- Similar to male except body more slender; anterior margin of pronotum unarmed; declivity confined to posterior third, more strongly convex, steep, devoid of spines and large granules; elytral scales more uniformly distributed.

Distribution.- Oaxaca.
USA: Oaxaca: 27 km W Tehuantepec, 8-VII-53, 200 m , and 25 km W Tehuantepec, 22-VI-67, 200 m , No. 85 , S. L. Wood.

Biology.- Specimens were taken from the cambium region in a dying limb 8 cm in diameter of a small, spineless, leguminous tree having bipinnately compound leaves.

Notes.- The above treatinent was based on the male and female paratypes in my collection and on 33 other specimens.

## 50. Pseudothysanoes costatus Wood

Pseudothysanoes costatus Wood, 1956, Canadian Ent. 88:236 (Holotype, male; Madera Canyon. Santa Rita Mts., Arizona; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species belongs to the heliura group of species, but it differs from all other species in the group in having the lateral declivital costa in the male extend only from the elytral apex to interstriae 9 . Additional distinguishing characters appear in the above key.

Male.- Length $1.0-1.2 \mathrm{~mm}, 2.7$ (female 3.0) times as long as wide; color dark brown.

Frons flattened and minutely punctured on lower half, convex and granulate-reticulate above; vestiture of coarse, short setae of moderate abundance on upper area. Antennal scape elongate, slender; club small, oval, sutures obscurely indicated.

Pronotum 0.93 times as long as wide; widest on basal half, sides on basal half arcuate, not converging, distinctly constricted on anterior half, rather broadly rounded in front; anterior margin armed by four subcontiguous teeth, lateral pair submarginal; summit at middle; anterior slope asperate; posterior area almost smooth, punctures minute, sparse. Vestiture on disc consisting of a few erect scales; a few subplumose bristles on anterior area.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures coarse, deep; interstriae less than half as wide as striae, punctures fine. Declivity convex, rather steep; strial punctures greatly reduced in size; interstriae wider, with fine granules; an acutely elevated subcostal margin extends from elytral apex to interstriae 9.

Vestiture consisting of rows of fine, short, strial hair, and rows of interstrial bristles; each bristle short, about twice as long as wide, usually entirely abraded on declivity.

Female.- Similar to male except more slender; frons shallowly concave to upper level of eyes, impressed area smooth, shining; anterior margin of pronotum unarmed; strial punctures small, interstriae wider than striae; elytral declivity shorter, steeper, more narrowly convex; declivital interstriae devoid of granules; interstrial scales more generally distributed on declivity.

Distribution.- Arizona.
LSA: Arizona: Madera Canyon, Santa Rita Mts., 16-VII-52, Quercus, W'. E. La Berge.

Biology.-Specimens were taken from the bark of oak twigs.

Notes.- The above treatment was based on the three male and one female paratypes in my collection.

## 51. Pseudothysanoes vesculus Wood

Pseudothysanoes veseulus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):24 (Holotype, male: 3 km W Armeria, Colima, Mexico: Wood Coll.)
Diagnosis.- This species is distinguished from heliura Wood by the smaller size, by the more slender form, by the nonelevated apical margin of the male declivity, and by the excavated female frons that bears a tuft of minute setae toward the vertex.

Male.- Length $0.9-1.1 \mathrm{~mm}, 2.4$ times as long as wide, color brown.

Frons not visible on only male studied. Antennal scape long; sutures on club largely obsolete.

Pronotum 0.97 times as long as wide; widest near base, sides weakly arcuate, converging slightly before broadly rounded, unarmed anterior margin; summit distinct, asperate on anterior slope, subshining, minutely, obscurely punctured and with obscure lines in posterior area; vestiture with scales and short stout hair intermixed.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides straight, increasing very slightly posteriorly to obliquely truncate declivity; striae not impressed, punctures distinctly impressed; interstriae wider than striae, punctures uniseriate, fine, obscure. Declivity obliquely truncate, face evenly,
weakly convex, an acutely elevated ridge extending from suture at base around margin of declivity about three-fourths distance to sutural apex, obsolete on this final fourth; strial and interstrial punctures equal in size, very close, moderately deep over entire face. Vestiture consisting of rows of interstrial scales and short strial hair; scales on disc about three times as long as wide, increasing slightly in length toward declivity; declivital margin bearing a ring of closely set, much larger, stout scales; scales on declivital face uniform in size, much smaller and more slender than on disc.

Female.-Similar to male except frons shallowly, broadly concave from epistoma to vertex, median third of upper half densely pilose; strial punctures finer; declivity convex, without elevated margin, sculpture essentially as on dise but slightly deeper; vestiture as on dise and somewhat finer.

Distribution.-Colima.
Mexico: Colima: 3 km W Armeria, 28-VI-65, 70 m , No. 136 (not 131), S. L. Wood.

Biology.-Specimens were taken from a small, cut, thornless tree 8 cm in diameter.

Notes.- The above treatment was based on the type series of the male holotype and five females.

## 52. Pseudothysanoes heliura Wood

Pseudothysanoes heliura Wood, 1956, Canadian Ent. 85:237 (Holotype, male; Luling. Texas; Snow Ent. Mus., Univ. Kansas)
Diagnosis. - This is the largest known species in the heliura species group. It is distinguished from vesculus Wood by characters summarized in the above key.

Male.- Length $1.3-1.5 \mathrm{~mm}, 2.4$ (female 2.6) times as long as wide; color dark brown.

Frons transversely impressed at level of antennal insertion, convex above; surface smooth, shining in central area of lower third, rather coarsely reticulate-granulate in convex area; vestiture sparse, rather short, moderately coarse. Antennal scape slender, elongate; club widest on distal half, sutures obscure.

Pronotum 0.93 times as long as wide; widest on basal third, sides arcuately converging to moderate constriction on anterior half, rather broadly rounded in front; anterior margin armed by about six small teeth;
summit at middle, rather high; anterior slope asperate; posterior area coarsely reticulate, with fine, sparse, obscure punctures. Vestiture a mixture of short, fine hair and slender scales in posterior area, a few stout bristles in asperate area.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal three-fourths, obtusely angulate behind; striae not impressed, punctures small, deep; interstriae about twice as wide as striae, minutely irregular, punctures fine, uniseriate. Declivity margined from elytral apex to declivital base by an elevated circumdeclivital ridge; declivital face rather steep, convex; declivital punctures moderately large, close, deep, confused; declivital face completely unarmed by tubercles or granules; circumdeclivital ridge a costa of almost uniform height except slightly higher toward apex. Vestiture of rows of minute strial hair on disc and rows of erect interstrial scales; scales on declivital margin longer, wider, closely set.

Female.- Similar to male except body more slender; frons more extensively, more deeply impressed almost to upper level of eyes; anterior margin of pronotum unarmed; interstrial punctures on disc finely granulate; circumdeclivital ridge entirely absent; declivital striae as on disc, declivital interstriae with fine punctures; declivital vestiture as on disc but slightly longer, scales each about four times as long as wide, equal in length to distance between rows.

Distribution.- Texas.
USA: Texas: Luling, 30-III-51, Condalia obtusifolia, S. L. Wood; Brownsville, VI.

Host.- Condalia obtusifolia.
Bıology.- This xylophagous, bigamous species constructed parental and larval gallery systems very similar to Micracis in stems about 3 cm in diameter.

Notes. - The above treatment was based on 18 paratypes and on one other specimen.

## 53. Pseudothysanoes spinura Wood

Pseudothysanoes spinura Wood, 1959. Great Basin Nat. 19:58 (Holotype, male: Oak Creek Canyon, Arizona, Wood Coll.)
Diagnosis.- This species belongs to the heliura group; it is distinguished from
mancus Wood by characters summarized in the above key.

Male.- Length $1.1-1.3 \mathrm{~mm}, 2.4$ (female 3.0) times as long as wide; color dark brown.

Frons and pronotum as in heliura except anterior margin of pronotum slightly produced medially and armed by only four teeth; pronotal disc almost smooth, obscurely reticulate, punctures minute.

Elytral dise as in heliura, declivity more narrowly convex in central area, more broadly impressed laterally; strial punctures in rows, obscure on 1 ; declivital interstriae 1 with four to six coarse, very long, pointed bristles, a fine granule at base of each bristle; circumdeclivital ridge not as high on upper third.

Female. - As in female heliura except frons more abruptly impressed above epistoma, impression extending as a narrow, median groove to a very deep, foveate impression at upper level of eyes; interstrial punctures fine, not granulate; elytral scales shorter, more widely spaced.

Distribution.- Arizona and Chihuahua.
USA: Arizona: Oak Creek Canyon, 20-VIII-58, 30-IX60, Ceanothus integerrimus; Cave Creek, Chiricahua Mts., 7-VI-69, 2300 m , Ceanothus integerrimus. MEXICO: Chihuahua: 10 km N Chihuahua, 2l-VII-60, (?) Rhus; all taken by me.

Host.- Ceanothus integerrimus.
Biology.- This species was taken from phloem tissues of branches about 2-4 cm in diameter.

Notes.- The above treatment was based on the type series of 24 specimens and on 46 other specimens.

## 54. Pseudothysanoes mancus Wood

Pseudothysanoes mancus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):24 (Holotype, male; 3 km E Armeria, Colima, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from spinura Wood in the male by the steeper elytral declivity, with the circumdeclivital elevated costa higher and more acute particularly on the upper half, and, in the female, by the very deeply excavated frons.

Male.- Length $1.0-1.2 \mathrm{~mm}, 2.4$ (female 2.8) times as long as wide; color dark brown.

Frons as in spinura except impression slightly deeper.

Pronotum 0.97 times as long as wide, otherwise as in spinura.

Elytra evidently 1.5 times as long as wide, as in spinura except declivity slightly steeper, circumdeclivital costa more strongly, subacutely elevated from sutural margin above to sutural margin below; spinelike setae on declivital interstriae 1 six in number and at least as large; vestiture similar.

Female.-As in the female of spinura except frons very deeply excavated on median three-fourths from epistoma to vertex, deepest point at upper level of eyes; general surface of elytral declivity more irregular.

Distribution.-Colima.
MEXICO: Colima: 3 km E Armeria, 28-VI-65, 70 m , No. 131, S. L. Wood.
Biology.-Specimens were taken from phloem tissues of a recently cut limb of an unidentified thorn tree.

Notes.- The above treatment was based on the type series of 36 specimens.

## 55. Pseudothysanoes yuccae (Wood)

Cryptocleptes yuccae Wood, 1956, Canadian Ent. 88:239 (Holotype, female; Tecamachalco, Puebla, Mexico; Snow Ent. Mus., Univ. Kansas)
